28. G. *ſegetum*. Ker in Curt. Mag. t. 719. Dryandr. in Ait. Hort. Kew. ed. 2. v. 1. 102. (G. communis; Bulliard. Herb. de la France, t. 8. Sm. Fl. Græc. Sibth. v. 1. 27. t. 37, 38. Lamarck Illuſtr. t. 32. Tourn. t. 190. G. italicus; Ger. em. 104.)—Leaves many-ribbed. Spike one-ranked. Flowers horizontal; upper ſegment diſtant; three lowermoſt equal, each with a linear-lanceolate bordered ſtripe.—Native of corn-fields in the ſouth of Europe, common in Italy, Greece, and the neighbouring countries, flowering in the ſpring; hardy, but not frequent in gardens. It is diſtinctly repreſented in the Hortus Eyſtetenſis, by the name of *Victorialis rotunda;* Ord. Eſt. 4. t. 10. f. 2, though the other *Gladioli* of that huge book are leſs preciſe. This is diſtinguiſhable from the two laſt by the diſtance between the uppermoſt lobe of its *bloſſoms* and the two next, which are peculiarly narrow; while the *ſeeds*, according to Mr. Ker, are round, with a ſomewhat pulpy coat, not flattened and winged as in the whole of the genus beſides, which is a moſt material ſpecific diſtinction, and even forms an exception to one of the generic characters. Mr. Ker ſuſpects the exiſtence of other European ſpecies, ſtill confounded as varieties of theſe, and which may perhaps account for anomalies and incongruities in the figures of authors. Whether t. 38. of Flora Græca may be one of theſe, we muſt ſubmit to future enquiry. Though ſmall, it is ſaid to be a native of fertile ground; the three upper ſegments ſeem more approximated, and the three lower ones united by a longer baſe, than in t. 37, our G. *ſegetum;* but this we learn merely from the figure, nor was the artiſt acquainted with the characters ſubſequently found out in this tribe, ſo as to give peculiar authority to what he has expreſſed in his drawing. The acquiſition of living ſpecimens at ſome future time can alone ſettle the queſtion.—It is proper to mention that G. *ſpicatus* of the Linnæan herbarium, alluded to by Mr. Ker, is a Siberian ſpecimen, with very broad lateral ſegments to the corolla, and as far as we can judge ſeems rather to be *communis*, if not, as is poſſible, a ſpecies hitherto undefined. It is probably different from the African plant of Van Royen, intended in Sp. Pl. ed. 1, nor has it the authentic marks of originality. What might chance to be compared with it in the Bankſian herbarium, when none of the parties preſent had any preciſe ideas about theſe plants, we cannot anſwer for, but our ſpecimen was then voted to be *communis*.

29. G. *imbricatus*. Linn. Sp. Pl. 52. Lamarck. Dict. v. 2. 723.—Leaves many-ribbed, ſpike of numerous, crowded, upright flowers; upper ſegment rather diſtant; three lowermoſt nearly equal.—Gathered by Gerber near Luban in Livonia. His own ſpecimen in the Linnæan herbarium is the only one we have ſeen, nor do recent writers appear to know any thing of this ſpecies, which appears to us very diſtinct, akin to the three laſt in *leaves* and habit; but differing widely in its curved aſcending *ſpike*, and crowded erect *flowers*, which are ſmaller than thoſe of G. *communis*, of a purple or crimſon colour, pervious at the baſe, in conſequence of a conſiderable diſtance between the claws of the upper and lateral ſegments, while their upper parts ſeem to fold over each other; but of theſe characters we cannot, of courſe, ſpeak abſolutely, from the dried flowers; the three lowermoſt ſegments ſeem equal and rather narrow. No white ſtripe is diſcernible in their preſent condition. The *leaves* riſe above the ſpike of flowers, and have each an oblique point, but this may not be conſtant.

Whatever ſpecies of *Gladiolus* (excluſive of ſuch as are now referable to the genera *Sparaxis*, *Anomatheca*, *Tritonia*, *Watſonia*, *Melaſphærula* or *Babiana* of Mr. Ker), may be found here and there in authors, we decline deſcribing without ſeeing living ſpecimens. The diſcordance between ſeveral of the figures, above quoted for the ſame ſpecies, proves how variable many of them are, eſpecially from accidental circumſtances in cultivation. The Botanical Magazine is now become a faithful and valuable repoſitory of this family, ſo that however botaniſts may differ about definitions, the memory of the plants can never be entirely loſt.

GLADIOLUS, in *Gardening*, compriſes plants of the tuberous-rooted, flowery, perennial kind; of which the ſpecies moſtly cultivated are the common ſword-lily, or corn-flag (G. communis); the imbricated flowered gladiole (G. imbricatus); the ſquare-ſtalked gladiole (G. triſtis); the narrow leaved gladiole (G. anguſtus); and the ſuperb ſcarlet gladiole (G. cardinalis).

There are ſeveral varieties of the firſt ſpecies, as the Italian and French corn flags, with the bluiſh, the white, and the ſmall purple coloured.

Method of Culture.—In the firſt ſort and varieties the culture may be readily effected by planting the off-ſets from the old roots in the beginning of the autumn in the places where they are to grow. And the other ſorts may be raiſed in the ſame way as well as by ſeeds. Theſe ſhould be planted in a warm border, and be protected in the winter by glaſs or ſome other means, when there is a neceſſity for it, as during very ſevere weather, &c.

When increaſed by ſeed it ſhould be ſown towards the end of Auguſt, in pots filled with light earth, placing them in a ſhady ſituation at firſt, but afterwards where they may be expoſed to the ſun, being protected during the winter in a hot-bed frame, free air being admitted when the weather is mild. In the ſpring the pots ſhould be removed to a ſhady ſituation, with only the morning ſun. When the ſtems decay, the roots ſhould be taken up and kept in ſand in a dry place till the time of planting. In the ſecond year's planting they ſhould be put in ſeparate ſmall pots, filled with mould formed from the turf or ſward.

With reſpect to the old roots they may be taken up every two or three years, to have the off-ſets taken off from them, in order to their future increaſe.

All the ſorts afford a fine effect and variety in the flower borders and other parts among other plants of the flowery kinds, being properly arranged in mixture with them.

GLADIUS, SWORD. *Jus Gladii*, or *right of the ſword*, is uſed, in our ancient Latin authors, and in the Norman laws, for ſupreme juriſdiction.

Camden, in Britannia, writes "Comitatus Flint pertinet ad gladium Ceſtriæ:" and Selden, Tit. of Honour, p. 640. "Curiam ſuam liberam de omnibus placitis, &c. exceptis ad gladium ejus pertinentibus."

And it is probably from hence, that at the creation of an earl, he is *gladio ſuccinctus*; to ſignify, that he had a juriſdiction over the county.

GLADIUS *piſcis*, in *Ichthyology*, a name uſed by many for the ſword-fiſh, called alſo the *xiphias*, which ſee.

GLADKA, in *Geography*, a fort of Ruſſia, in the government of Caucaſus, on the Malva; 36 miles W. of Kiſliar.

GLADWIN. See IRIS.

GLADWIN, JOHN, in *Biography*, the late organiſt of South Audley chapel, was the firſt performer on the organ at Vauxhall, after the building of the orcheſtra in the middle of the gardens, and the eſtabliſhment of a regular band. He was a pleaſing player in his day, and a worthy man, who lived to a great age, and died in 1799.

GLAIR *of Eggs*, is the ſame as the white of eggs, and is uſed as a varniſh for preſerving paintings. For this purpoſe it is beat to an unctuous conſiſtence, and commonly mixed with a little brandy or ſpirit of wine, to make it work more freely, and with a lump of ſugar to give it body and prevent its cracking; and then ſpread over the picture or painting with a bruſh.

GLAIZE, AU, in *Geography*, a S.S.W. branch of the Miami of the lake in America, which interlocks with St. Mary's river. By the treaty of Greenville, the Indians have ceded to the United States a tract of land, ſix miles ſquare, at the head of its navigable waters, and ſix miles ſquare at its confluence with the Miami, where port Defiance now ſtands.

GLAMA, in *Zoology*. See CAMELUS.

GLAMMISS, in *Geography*, a ſmall town in the county of Forfar, Scotland, contains 385 houſes, and 1931 inhabitants. Here are two ſmall manufactories of yarn, and coarſe linen cloth. The earls of Strathmore formerly poſſeſſed, and occupied a noble caſtle in this pariſh. The remains of this baronial fortreſs are ſtill very conſiderable, and occupy a commanding ſcite on the banks of the river Dean. In this pariſh are ſeveral ancient obeliſks, or ſtone croſſes; alſo many cairns. Theſe are traditionally ſaid to commemorate the murdered king Malcolm II. Glammiſs is divided into two parts reſpectively, called the New, and the Old Town.

GLAMORGANSHIRE, the ſouth maritime county of South Wales, is ſuppoſed to have derived its name from having afforded a temporary, though inſecure, retreat to an ancient prince, at a very early period of Britiſh hiſtory. The ſtory is briefly recapitulated by Spenſer, in his Chronicle of Britiſh kings. (Fairy Queen, b. ii. c. 10.) Glamorgan was in ſucceeding ages an independent ſovereign principality, diſtinct, as thoſe who profeſs to be acquainted with the ancient hiſtory of Wales aſſert, from the rule and government of South Wales. The principality, or ſovereign lordſhip of Glamorgan, as theſe perſons ſay, contained the preſent counties of Glamorgan and Monmouth, the ſouthern and eaſtern parts of Brecknockſhire, and that part of Herefordſhire lying to the weſt of the river Wye.

The lordſhip of Glamorgan was ſubdivided, at an early period, into a great many petty lordſhips, in every one of which their lords exerciſed "jura regalia," reſerving, however, to the ſubject a right of appeal to the court of the chief lord, or, as he was termed, the lord paramount. There are at leaſt 50 ancient buildings ſtill remaining in the diſtrict, univerſally underſtood to be the halls in which the courts of legiſlation and of juſtice were held for the reſpective petty lordſhips. They are now commonly called "Church-houſes," and belong to the pariſhes in which they ſtand. They are at preſent uſed as ſchool-rooms, and occaſionally for dancing; an amuſement ſtill common in Glamorganſhire, though now beginning to decline. The ground-floor apartments under theſe halls are uſed as alms-houſes for the poor of the pariſh. From ancient ſurveys and other accounts of the lordſhips it appears that before the reformation a market was held in each of theſe halls every Sunday morning, till the tolling of the firſt bell, which is ſaid to have been intended as a notice for the buſineſs of the market to ceaſe. The ſecond bell was a ſignal of preparation for church, and the third for the commencement of divine ſervice, during which no door, but the church door, was allowed to be ſeen open.

This county, extending about forty-eight miles from eaſt to weſt, and 27 from north to ſouth, is bounded on the N. by Brecknockſhire, on the E. by Monmouthſhire, from which it is ſeparated by the river Remny, on the S. by the Briſtol channel, and on the W. by Caermarthenſhire. The greateſt part of the ſea-coaſt forms a ſemi-circular courſe; the weſtern extremity being formed into a narrow beak between the open channel on the one hand, and an arm running round to the Caermarthenſhire coaſt on the other. (See GOWER.) An ample account of the manner in which the lordſhip of Glamorgan was obtained by its conquerors, is to be found in Powel's Hiſtory of Wales, written in the time of Elizabeth, or in Evans's edition of Wynne's Hiſtory of Wales. The following abſtract is taken from Malkin's work. Jeſtin ap Gurgant, a petty prince of odious character, waged war, in the year 1088, againſt Rees ap Tudor, and was aſſiſted by Eneon ap Collwyn. Unable to make any impreſſion on his enemy's dominions, Jeſtin commiſſioned Eneon to go to England, and to procure ſome more powerful ally. His propoſitions were eagerly received by Robert Fitzhawen, and twelve other Norman adventurers, who came to Glamorgan on an expedition, profeſſedly for the purpoſe of retrieving the affairs of Jeſtin. The allies, marching againſt Rees ap Tudor, came up with his forces on the borders of Brecknockſhire. In a battle which enſued at a place called Hirwin, Rees was entirely defeated: and in his flight was taken priſoner, and put to death. On this occaſion, Jeſtin betrayed his characteriſtic treachery, by violating his agreement with Eneon, to whom he had promiſed his daughter in marriage, as a recompence for his ſervices. Eneon, juſtly offended, was determined on revenge; and therefore, when the Normans, after having fulfilled their engagements, and having obtained ſatisfaction for their ſervices, quietly returned home, Eneon repreſented the injuries he had ſuſtained by the treachery of Jeſtin, and alſo the hatred of the country to its tyrant. He alſo ſtated how eaſy it was to obtain poſſeſſion of this feeble country, with the aid of the different princes at variance with Jeſtin. R. Fitzhawen, and his ſoldiers of fortune, availing themſelves of the favourable moment, turned their arms againſt their employer, who was unprepared for ſo formidable a reverſe, and overran the country; whilſt Jeſtin ſaved himſelf by flight, and died ſoon after, unlamented and unrevenged. Fitzhawen, upon a diviſion of the conquered territory, took for his own ſhare the caſtles of Cardiff and Kenſig, with the market town of Cowbridge, and the demeſne of Llantwit; appropriating to himſelf the lands belonging to them, together with the ſovereignty of the whole country. The other parts were diſtributed in various proportions among his followers. Eneon ap Collwyn, in particular, poſſeſſed Caerphilly, with Jeſtin's daughter in marriage, the prize which occaſioned the conteſt. (See WALES.) With reſpect to the pictureſque character of this county, it is diſtinguiſhed by unbounded variety. It has ſea, mountains, valleys and rivers; and it is ſaid to reſemble North Wales in general aſpect more than any of the ſix counties. Its mountains are not ſo high as thoſe of Brecknockſhire, but they preſent, in a conſiderable degree, the appearance of Merionethſhire, by their extreme abruptneſs, which imparts an air of wildneſs to the country, and of elevation exceeding the reality to them. They differ, however, in one material reſpect, that they exhibit greater traces of cultivation and occupancy. Glamorganſhire lies under the imputation of want of wood; but this is only true of its level and moſt cultivated parts. The obſervation does not apply either to its eaſtern or weſtern extremities. Thoſe who know the banks of the Taff, the two Ronthas, and the Cunno, the wilds of Abudarr, and Yſtradyvodwg, have ſeen ſuch woods and groves as are rarely to be found. The magnificently clothed hills of Margam, Bagland, Britonferry, and the vale of Neath, unite the beauties of cultivation with the unfelled luxuriance of foreſt ſcenery. Glamorganſhire produces with ſufficient liberality oak, aſh, beech, and all the common foreſt-trees, except elm, which is obſerved not to be indigenous. On the north and north-eaſt ſides this county is very mountainous; and in ſome parts preſents rugged rocks, and in others a ſoil covered with plenty of fine wood, and concealing rich mines of coal and iron. A tract of land can ſcarcely any where be found more inviting to ſcientific cultivation than the vale of Glamorgan, between the mountains and the ſea; and yet it is obſerved that the agriculture of this county does not keep pace with the fertility of the ſoil. In addition to natural fruitfulneſs, they have lime every where at command for manure; and this facility affords a ſtrong temptation to that act of injuſtice which the farmers call "driving the land." In Glamorganſhire, good land, ſituated near a conſiderable town, lets almoſt as high as within five miles of London; but land among the northern hills, ſcarcely reclaimed, and from its locality irreclaimable to any very lucrative purpoſe, is of courſe low in its rent, and occupied only by tenants, natives of the hills, and unacquainted with the ſuperior advantages and comforts enjoyed by the farmer in the vale. Another circumſtance which materially affects the value of farms, is right of mountain; where that is attached to an eſtate, it compenſates in ſome degree for diſtance from markets or poverty of ſoil. Theſe conſiderations are applicable to other counties as well as Glamorganſhire. But what diſtinguiſhes and enriches this county above all the reſt is the profuſion of coal, iron, and lime-ſtone, with which it almoſt every where abounds. The earth, indeed, of which it is compoſed, taken externally and internally, ſeems to be full of every thing neceſſary to the uſe and convenience of man. Manure, metal, and the means of manufacturing that metal, are all found on the ſame ſpot; ſo that induſtry is exerted at the leaſt poſſible expence, and conſequently to the greateſt poſſible advantage. The rivers, and mountain torrents, ſo remarkable in this diſtrict, afford an ample ſupply of water for all the purpoſes of life, as well as the means of procuring that artificial and cheap conveyance which is among the moſt ingenious improvements of the preſent age. With reſpect to that moſt extenſive bed of lime-ſtone, of which nearly the whole of Glamorganſhire forms only a part, it commences with the eaſtern extremity of the county, and, taking a direction due weſt, runs in a ſtraight line to Swanſea bay, appearing again in Gower, and, having paſſed under Caermarthen bay, is ſeen to occupy in great part the ſouth and weſt of Pembrokeſhire; it then takes its courſe through St. George's channel, and is found in Ireland in that exact bearing which unqueſtionably marks its continuity.

The air on the N. ſide of the county is ſharp, occaſioned by the long continuance of the ſnow on the hills; but on the S. ſide mild and temperate, occaſioned by the ſea-breezes. That in the vicinity of Margam is deemed peculiarly ſalubrious.

The antiquity of the cottages is a ſtrongly marked feature in the appearance of this county. Many of them are probably as ancient as the caſtles, to which they were attached. Their architecture is particularly deſerving of notice. The pointed door-ways, and pointed windows, ſufficiently evince their date; and though Welch towns are univerſally cenſured by ſtrangers, for the inelegance and inconvenience of their houſes, the direct reverſe is the fact with reſpect to the habitations of the peaſantry. There is one circumſtance, beſides their general ſtructure, that of many of which is the ancient Gothic, which adds to the reſpectable appearance of the cottages, and that is, the univerſal practice of lime-whitening them. This has been the cuſtom of the county from very remote ages, and is extended even to the barns and ſtables, to the walls of yards and gardens. It is noticed and praiſed in the moſt ancient Welch poems, and certainly evinces a very early ſenſibility to the arts and decencies of life. The price of proviſions in this county has of late very much increaſed, and is comparatively very high, on account of the increaſed demands of the manufacturing diſtricts, which are numerous. The price of labour is equally enhanced from the ſame cauſe. The increaſe of population, owing to the influx of commerce, and the magnitude of its eſtabliſhments at Swanſea, Merthyr-Tydvil, Neath, Aberavon, Melin Gruffydd, near Cardiff, where are the largeſt tin works in the kingdom, &c. afford another reaſon why the cheap comforts and elegancies of life are no longer to be ſought for here.

The dreſs in Glamorganſhire is not ſo ſtrongly marked as in ſome other counties, except that the women univerſally adopt the man's hat; but they wear it with a very good grace, and are remarkably neat in their attire, as well as comely in their perſons, and graceful in their carriage; which may probably be attributed to the habit of dancing, which is their favourite amuſement. Their modes of greeting are unuſually affectionate, ſometimes bordering on the ludicrous, particularly among the women, who are conſtantly ſeen ſaluting each other at market, and on the moſt ordinary occaſions of buſineſs, as well as on occaſions of diſtreſs. At a wedding it is the cuſtom of all who are invited, both men and women, to ride full ſpeed to the church porch, and the perſon who arrives there firſt has ſome privilege or diſtinction at the marriage feaſt. In caſe of death, the bed on which the corpſe lies is always ſtrewed with flowers, and the ſame cuſtom is obſerved after it is laid in the coffin. It is an invariable practice, both by day and night, to watch a corpſe; and the hoſpitality of the country is no leſs remarkable on melancholy than on joyful occaſions; for the invitations to a funeral are very general and extenſive; and the refreſhments are not light, and taken ſtanding, but ſubſtantial and prolonged. The grave of the deceaſed is conſtantly overſpread with plucked flowers for a week or two after the funeral: the planting of graves with flowers is confined to the villages, and the poorer people. It is very common to dreſs the graves on Whitſunday, and other feſtivals, when flowers can be procured.

The Roman ſtations, forts, and camps, in this county, are generally underſtood to be at Cardiff, Caerphilly, and Caera, which lies between Wenvoe, a large handſome houſe built in the caſtellated form, and the Cardiff road. The great Roman road was over Newton Down, leaving the preſent road on the right, and paſſes through Kenfig to Margam, and as ſtraight as the nature of the country will admit, through Aberavon pariſh to Neath. Glamorganſhire contains one epiſcopal town, *viz.* Llandaff, and ſeveral others, as Cardiff, the capital of the county, Caerphilly, Llantriſent, Cowbridge, Bridgend, Neath, Merthyr-Tydvil, and Swanſea; which ſee reſpectively. The principal rivers are the Remney, the Taff, the Elwy, the Ronthas, great and ſmall, the Ogmore, the Cunno, the Nedd or Neath, the Tawe or Tave, and the Loghor. In this county are ſeveral rail-ways and canals. (See CANAL.) The canal from Merthyr-Tydvil to Cardiff was completed in the year 1798. From the tide-lock, where it enters Pennarth harbour, up to the town of Cardiff, it is navigable for ſhips of 400 tons; but from Cardiff to Merthyr-Tydvil, it is navigable for barges of 100 tons. The head of this canal at Merthyr-Tydvil is 568 feet five inches higher than the tide-lock two miles below Cardiff, where it falls into Pennarth harbour. This canal has upwards of 40 locks upon it in the ſpace of 26 miles, which is its whole length; and it is croſſed by more than 40 bridges. For an account of the bridge with one arch upon Taff; ſee BRIDGE. In a vale S. W. of Cardiff, near Duffrin houſe, and not far from the village of St. Nicholas, are ſome ancient monuments, ſuppoſed to be druidical. The moſt remarkable of theſe monuments is a grey ſtone, which claſſes among thoſe pieces of antiquity called Cromlechau. (See CROMLECH.) This monument is ſupported by five large ſtones, encloſed entirely on the eaſt, weſt, and north ſides, and open to the ſouth, forming a conſiderably large, though low room, 16 feet in length, 15 wide, and, at the eaſt end, ſix feet high, but only 4½ at the weſt end. The rubbiſh about it prevents the inveſtigation of its original height. The ſupporting ſtone to the north is 16 feet long; that on the weſt end about nine feet in length. At the eaſtern extremity three ſtones are ſet cloſely together; the middle ſtone is 4½ feet wide, the northern ſtone of theſe three about three feet, and the ſouthern nearly two feet in width. Theſe ſtones, ſtanding upright, ſupport a large ſtone on the top, which forms the roof of this rude apartment. The length of this horizontal ſtone is 24 feet; it is 17 feet in its wideſt part, and of different breadths at other places; it is 10 feet at one extremity, and 12 about the middle; and from two feet to two and a half thick. The area of the top-ſtone, therefore, having for its mean breadth 13½ feet, and 24 feet for its length, will contain 324 ſquare feet; whence it appears that it is nearly thrice as large as that of the famous cromlech, near Newport in Pembrokeſhire. Near this cromlech are other heaps of ſtones called Carneu or Cairn. Of theſe cromlechs different opinions have been entertained. Some have ſuppoſed them to be places of ſhelter for the Druids, who always worſhipped in the open air, and after them, for the firſt Chriſtian prieſts, in rain and other inclemencies of the weather; others have ſuppoſed them to be oratories, from the tops of which they delivered their diſcourſes; and others again, that they were altars on which victims were offered in the times of Druidiſm.

Glamorganſhire is divided into ten hundreds, and 118 pariſhes, which, in 1801, contained 71,525 inhabitants, of whom 6903 were employed in trade and manufacture, and 18,515 in agriculture. Two members are returned for Glamorganſhire to the Britiſh parliament, *viz.* one for the county, and one for the boroughs, Cardiff, &c. Malkin's South Wales.

GLAMOUR, or GLAMER, an old term of popular ſuperſtition in Scotland, denoting a kind of magical miſt believed to be raiſed by ſorcerers, and which deluded their ſpectators with viſions of things that had no exiſtence, altered the appearance of things really exiſting, &c.

GLAN, a river of France, which runs into the Nahe, three miles E. of Sobernheim.—Alſo, a river of Carinthia, which riſes near Koſtnberg, and joins the Gurck, four miles E. of Clagenfurt.

GLAND, in *Anatomy*, is a name applied to thoſe organs of the body, which ſeparate from the blood conveyed to them by their blood-veſſels various ſubſtances, generally of a fluid nature, and diſcharge them through one or more tubes, called excretory ducts. The term however has been, and is employed more extenſively, having been applied to various organs, which, although analogous in their ſtructure, on ſuperficial obſervation, to thoſe already deſignated, do not reſemble them at all in their functions. Thus, the ſmall bodies belonging to the lymphatic ſyſtem have been called lymphatic or conglobate glands; although the knowledge hitherto acquired by phyſiologiſts concerning the action of theſe bodies, and their anatomical relations and connections do not warrant us in aſcribing to them any function ſimilar to thoſe exerciſed by the glands properly ſo called: the account of theſe will be found under the articles ABSORBENTS and ABSORPTION. The pineal, thyroid and thymus glands, the renal capſules and the ſpleen, have all been included in the glandular ſyſtem of the body, but will not be conſidered in this article, as we know nothing at all of their offices, and have no reaſon to ſuppoſe that they ſecrete any fluid. Our definition will include the ſalivary, lacrymal, and Meibomian glands, the tonſils, the ceruminous glands of the ear, and the ſebaceous glands of the face, in the head; the mammary glands in the cheſt; the liver, pancreas, and kidneys in the abdomen; the proſtate, teſticle, Cowper's glands, and glandulæ odoriferæ about the penis; and the extenſive ſyſtem of mucous glands about the head and trunk. Theſe parts, although differing widely from each other in many reſpects, agree in a ſufficient number of points to allow of their being arranged in one organic ſyſtem, which has been named the glandular: the other organs juſt enumerated, belonging to this only in name, are excluded from the arrangement by their texture and properties, their mode of vitality and functions. The extremities contain no parts belonging to the glandular ſyſtem; the fluids formed in the different organs of this apparatus belong almoſt entirely to the organic functions, while the limbs are particularly deſigned to execute the offices of the animal life.

As the phyſiology of theſe organs cannot be conveniently ſeparated from the hiſtory of their ſtructure, we ſhall conſider the vital properties as well as the organization of the glandular ſyſtem; and we ſhould make a very unnatural and arbitrary diviſion of the matter, if we did not give at the ſame time a view of ſecretion in general. We ſhall preſent the reader, in the firſt place, with an enumeration and arrangement of the ſecreted matters; we ſhall proceed, ſecondly, to give a general view of the organization of the glandular ſyſtem; and ſhall exhibit, in the third and laſt place, the opinions of phyſiologiſts concerning the mode of action of the glands and the ſubject of ſecretion in general. The reader will obſerve that the preſent article is of a general nature; the ſtructure of the particular organs will be deſcribed on other occaſions, and detailed accounts of the nature and properties of the various fluids will be found under their reſpective titles, or in other articles of the work.

The blood, apparently an homogeneous fluid, is compoſed of various matters, which chemical examination can detect and ſeparate. It contains gelatine, albumen, fibrine, acids, alkalies, earths, ſaline and colouring matters, which are employed for the renovation of the ſolids and fluids of the body. It preſents theſe to the various organs, which, by converting them into their own ſubſtance, derive the means of ſupplying the waſte occaſioned by the natural actions of the parts, or form out of them various products, diſtinguiſhed by new characters, and extraneous to their own compoſition.

tion. The former of theſe proceſſes is nutrition or aſſimilation; the latter ſecretion: they reſemble each other in their commencement, in which the organ, by ſome powers of a nature entirely unknown to us, but peculiar to living bodies, and forming part of that complicated notion, which we expreſs by the term vitality, ſelects from the blood ſuch principles as ſuit its nature or functions; but they differ in the employment of what is thus ſelected, which is retained in the body, and aſſimilated to the already exiſting organization in the former caſe, and applied to ſome other purpoſe in the latter. The ſubject of nutrition does not come under our notice at preſent.

The products of ſecretion reſult from an eſſential change in the compound conveyed to the organ, from a new combination of the principles contained in the blood, which is transformed by the ſpecific action of the various organs into different fluids, retained in or expelled from the body, according to the qualities of each. Hence, there are organs which, after forming certain fluids, collect and retain them; while others ſeparate and expel their ſecretions from the body. The object of the ſecretions is, to collect thoſe which are deſtined to fulfil important uſes in the body; while that of the excretions is, on the contrary, to expel matters which would be injurious to the frame. The two functions then of ſecretion and excretion reſemble each other in moſt reſpects: there is in both a ſeparation and collection of fluids. The difference conſiſts in this, that in the former caſe the ſeparated fluid remains in the body, while it is ſoon expelled in the ſecond. Thus ſecretion always precedes excretion; and, in order to underſtand the latter, it is neceſſary to know how the former takes place.

The word ſecretion, derived from *ſecerno*, I ſeparate, ſignifies ſimply the act of ſeparating; and its phyſiological import is conveyed in that notion. It denotes, in phyſiology, that function of a living body, in which various fluids, differing from the blood and from each other, are prepared from the common maſs of the blood, the ſame fluid being conſtantly formed in the ſame organ. No part of phyſiology is more obſcure, and more difficult in its inveſtigation, than this very function. Malpighi, who had beſtowed great labour on the ſtructure of the glands, and was conſidered to have unveiled, in a great meaſure, the myſteries of their organization, confeſſes his ignorance on this ſubject; and, as the avowal, from ſuch a quarter, is intereſting, we ſubjoin the paſſage, obſerving that the remarks here made, concerning the kidnies, apply equally to all other ſecretions. He ſays of the urinary ſecretion, "quanam arte id contingat obſcuriſſimum: licet enim glandularum miniſterio totum hoc ſubſequi rationi ſit conſonum, quoniam tamen minima illa, ſimplexque meatuum in glandulis ſtructura nos latet, ideo quædam tantum meditari poſſumus, ut huic quæſito probabiliter ſatisfaciamus. Neceſſe eſt hanc machinam interna configuratione ſeparationis opus peragere; an vero his, quæ ad humanos uſus paſſim uſurpamus, quibus fere conſimilia effigimus, conſonet, dubium; licet enim occurrant analogæ ſpongiæ, incerniculi, fiſtularum cribrorumque ſtructuræ, cui tamen ex his conſimilis undequaque ſit renum fabrica, difficillimum eſt aſſignare, et cum naturæ operandi induſtria fecundiſſima ſit, ejuſdem ignotæ nobis reperientur machinæ, et quas nec mente quidem aſſequi licet. Illud miror tam copioſa, diverſaque corpora ſeparari per has glandulas in naturæ ſtatu, exit enim ſubſtantia aquea cum ſalinis, ſulphureis et conſimilibus particulis, et ex morbo etiam abſceſſuum reliquiæ, et totius quandoque corporis inquinamenta ſeparantur detentis ſanguineis particulis," &c. De Viſcerum Structura; De Renibus, cap. 6. The whole buſineſs is carried on in the minute, and, as we may call them, elementary parts of the viſcera and glands, the ſtructure of which eludes the reſearch of our ſenſes, and can ſtill leſs be developed by reaſoning or reflection. Obſervation cannot follow the work throughout; nor does it admit of elucidation by experiment, like ſome other ſubjects which have been explained by artificial imitation of the proceedings of nature.

Unwilling to confeſs their ignorance and leave their ſyſtems imperfect, phyſiologiſts have attempted to raiſe, on hypotheſes, that ſtructure, for which anatomy afforded no foundation. Their notions, reſting merely on probabilities and looſe analogies, have flouriſhed and fallen in ſucceſſion; and we ſhall find that the liſt of truths and aſcertained facts is much ſhorter than that of opinions and errors.

The compoſition of the ſecreted fluids preſents various differences in the nature and proportions of their conſtituent parts. They poſſeſs, in common, all the general characters which belong to animal ſubſtances: but each has certain particular diſtinctive qualities, depending on the various ſimple or compound principles, the union of which determines its ſpecific nature. Thus, ſetting aſide the reſemblance of all our fluids, conſidered as animal productions, fat does not reſemble bile; the latter is very different from milk; which, again, has no reſemblance to the ſalivary, gaſtric, pancreatic, ſeminal fluids, &c. which muſt be referred to ſo many different claſſes.

The arrangement of the animal fluids is more difficult than we ſhould have expected at firſt ſight. The falſe and imperfect notions, which were long entertained of their chemical compoſition, lead to claſſifications founded on the uſes to which they ſeemed to be deſtined. Thoſe employed in the nouriſhment and growth of the body were called recrementitious, ſuch as chyle, blood, ſerum, lymph, &c. The excrementitious included thoſe which are expelled from the body; as the urine, perſpiration, &c. A third claſs was made up of ſuch as partake of the characters of both theſe; of which a part is rejected as noxious, while the reſt is retained, in order to anſwer ſome particular purpoſe. Under the head of excremento-recrementitious humours, were arranged the ſaliva, bile, pancreatic juice, mucus of the inteſtines, &c. The objections to ſuch an arrangement are too obvious to need enumeration. This diviſion, as well as that before alluded to, of excretions and ſecretions, cannot be adopted with any benefit, while the nature and objects of many ſecretions are ſo little underſtood, that we cannot determine whether they are expelled as noxious, or ſerve very uſeful purpoſes in the economy. The bile, for example, has been very commonly deemed an excrementitious fluid, but by a completely arbitrary aſſumption: what proof have we that perſpiration ſeparates any thing noxious from the blood? For what reaſon is the ſecretion of the pancreas placed in one rather than in the other of theſe diviſions?

Pitcairne, who was followed by Michelotti, divided the animal ſecretions in a manner which has, at leaſt, the merit of ſimplicity, and leads to no falſe notions concerning their uſes; he diſtinguiſhed them merely as being thick or thin.

Haller diſtributed the fluids into four claſſes, according to the chemical notions of his time, and to the degree of complication in their elements. 1. The aqueous fluids. Theſe have a very large proportion of water in their compoſition; hence they are diſtinguiſhed by their fluidity, and have no ropineſs. Fire diſſipates them almoſt entirely, excepting a very ſmall proportion of earthy reſidue; neither alcohol nor acids coagulate them. Beſides a little earth, they contain ſome ſaline and oily matters. Many of our fluids belong to this diviſion. Some are expelled from the body, and are ordinarily deemed excrementitious; ſuch are the urine, which is not coagulable in the natural ſtate; the inſenſible Sanctorian perſpiration, and the pulmonary exhalation. Sweat is a mixed fluid, containing oily or ſebaceous matter, together with water. Several of the fluids, which are deſtined to ſerve particular purpoſes in the animal economy, contain very little except water. This is the caſe with the ſecretion of the proper ſalivary glands, with that of the pancreas and lacrymal gland; with the perfectly pure and tranſparent aqueous humour of the eye, and other watery fluids in the ſame organ.

2. Mucous fluids. Theſe differ from water in being leſs fluid; they are tenacious, ſo as to adhere to ſolid bodies, and ropy. They mix with water, are inſipid and inodorous, and nearly colourleſs. The evaporation of their aqueous parts reduces them into hard and dry cruſts. Acids do not coagulate them; but alcohol has a ſlight effect. They yield, on diſtillation, a large quantity of water, volatile ſalt, oil, and a carbonaceous reſidue. To this diviſion belong the lubricating fluids, which are poured out over the extenſive ſurfaces of the reſpiratory, digeſtive, urinary, and genital organs, and all the parts connected with them.

3. Gelatinous fluids; which are coagulable by heat, warm water, alcohol, and acids, remain fluid below 148° Fahrenheit; and have a mild or ſlightly ſaline taſte. Haller places in this order the ſerum of the blood, the lymph conveyed by the abſorbents, the water of the amnios, the ſerous exhalations of the circumſcribed cavities, the lymph of the cellular ſubſtance, and the fluid of the Graafian ovula. He alſo places in this diviſion the ſynovia of the joints, and the fluid of the tendinous thecæ; obſerving, at the ſame time, that theſe are partly compoſed of oily matters.

4. Oily fluids. Theſe are repreſented by Haller as more perfectly animalized productions: they are freed from the ſuperfluous quantity of water, and are inflammable; or at leaſt contain much of that matter which takes fire and deflagrates. At their firſt production they contain much water, ſo as not to be capable of inflammation, nor to poſſeſs their peculiar characters, but rather to reſemble mucus or gelatine: they undergo changes afterwards, which deprive them of their aqueous parts, and render them more viſcid and oily. The fat and the medullary ſubſtance of the bones, are the moſt extenſive ſpecimens of this order: it contains alſo ſebaceous matters of various kinds, as the greaſy cutaneous matter, the Meibomian ſecretion of the eye-lids, that of the glans penis, and of the external organs in the female. The bile, cruor of the blood, milk, and proſtatic fluid, belong to the ſame claſs.

Such are the four diviſions, in which Haller has arranged the animal fluids: he obſerves that ſeveral, being of a mixed nature, do not belong excluſively to either claſs, but ought, from the diverſity of their principles, to be referred to more than one: indeed there is hardly any, which can be rigorouſly ſaid to conſiſt of a ſingle element. Then, again, many evidently contain more fluids than one, formed ſeparately in the firſt inſtance, each in its appropriate organ, and afterwards mixed together. Thus the ſemen contains the ſecretions of the teſtis, proſtate, and veſiculæ; the ſweat is made up of the water of perſpiration with the cutaneous oil; the tears are a mixture of water, mucus, and ſebaceous matter; ſpittle contains water and mucus, &c.

The vaſt improvements in the ſcience of chemiſtry ſince the time of Haller muſt neceſſarily have ſubverted the baſis of the arrangement juſt deſcribed; which, when conſidered by a chemiſt of the preſent day, would be found open to objection at all points. The deficiencies of the claſſification are too obvious to render it neceſſary that we ſhould particularize them.

Blumenbach has claſſed the products of ſecretion on a ſomewhat different principle. "The ſecreted fluids," ſays he, "diſplay on one hand ſo much variety, while on the other they ſeem to be joined by ſo many points of affinity, that their arrangement in claſſes muſt be in great meaſure arbitrary. They may, however, be diſpoſed in the following order, according to the ſlighter or more eſſential changes and modifications which their elements, contained in the maſs of the blood, undergo in the ſecretory organs. Milk may be placed in the firſt rank, as conſiſting apparently of a very ſimple modification of chyle, and formed from the blood by a very eaſy proceſs after the influx of the chyle. The watery ſecretions come next, ſo called from their fluidity and tranſparency, although they differ materially from water in the nature of their conſtituent elements, particularly in containing a portion of albuminous coagulable matter—including the fluids of the eye; the tears, the matter of perſpiration, the exhalations in the cellular ſubſtance, and in the thoracic and abdominal cavities, to which the liquor pericardii and the fluid of the ventricles ſeem to be analogous. The urine, ordinarily referred to the aqueous fluids, is diſtinguiſhed by very remarkable peculiarities. The ſalivary fluids, concerned in the functions of maſtication, digeſtion, and chylification, ſeem to be rather more changed. Then follow the mucous ſecretions, ſpread over the ſurfaces of moſt of the viſcera belonging to the natural and generative functions, as well as the cavities of the noſe, larynx, and reſpiratory organs. The mucus in the interior of the eye, as well as that under the epidermis, do not appear to differ eſſentially from the preceding. Under the title of adipous fluids may be claſſed, beſides the common fat, the medulla of the bones, and the ſebaceous matter of the ſkin (including alſo the cerumen of the ears). The greaſy matter formed under the prepuce about the corona glandis of the male, and the ſimilar production in the female pudenda, may be referred to the ſame claſs; as well as the ſecretion of the Meibomian palpebral glands. The liquor of the amnios, and the ſynovial fluids, are commonly deemed gelatinous; but their real nature is not yet underſtood, neither is that of the fluid, hitherto unnamed, thrown out in the uterus under the venereal ſtimulus, known. The fluid contained in the early months of conception between the chorion and amnios, that of the veſicula umbilicalis, and that which ſurrounds the veſſels of the umbilical chord, is as yet little underſtood. The contents of the Graafian veſicles, and the proſtatic fluid, ſeem to be truly ſerous or albuminous. The male ſemen is quite a peculiar product, not to be compared to, or claſſed with, any other: and the ſame remark will hold good alſo of the bile." Inſtitut. Phyſiolog. ſect. 32.

The diviſion of this able phyſiologiſt would be natural and inſtructive, if the animal fluids deviated from the nature of chyle by gradations which could be eaſily perceived and marked. But we really cannot eſtabliſh among them any order correſponding to their natural compoſition; and the differences obſervable between chyle and fat, between the aqueous fluids and bile, conſtitute intervals, which we cannot appreciate or meaſure. Indeed there are often ſo many differences and ſo few relations between one fluid and another, that we can ſcarcely compare them at all.

The vaſt progreſs which chemiſtry has made of late years, and the valuable diſcoveries with which the analyſis of animal ſubſtances, as well as other parts of the ſcience, has been enriched; might have led us to expect that the claſſification of the fluids would have been reformed according to their conſtituent principles, and brought into a condition correſponding to the reſt of the ſcience. Fourcroy has indeed given ſuch a diſtribution of the ſubject in his Elements of Chemiſtry; but he does not ſeem to value the arrangement very highly, as he has not continued it in his laſt great work, the "Syſteme des Connoiſſances Chimiques." In proportion as the various animal products are analyſed with more accuracy, they are found to poſſeſs ſpecific characters which diſtinguiſh them from each other; and therefore render it impoſſible to refer them without impropriety to any general heads: accordingly in the moſt recent and able chemical works, they are enumerated and conſidered ſeparately. In this point of view, therefore, the exactneſs and perfection of modern analyſis renders our attempts at a general arrangement of the animal fluids unavailing; and it has only ſerved hitherto to ſhew the defects of ſuch methods.

Dumas, in his "Principes de Phyſiologie," adopts a different plan, which he calls a natural phyſiological one, and to which he aſcribes the advantage of connecting cloſely the knowledge of the fluids with that of their uſes. "This method," he obſerves, "which is the moſt natural and uſeful of all, is to refer the fluids to the various organic ſyſtems in which their ſecretion takes place, to make a claſs of humours for each ſyſtem, to conſider each of them as inſeparable from the ſyſtem to which it belongs, and to conduct the ſtudy of both together. We ſhall therefore have as many different claſſes or ſpecies of fluids as there are organic ſyſtems in the body. This ſimple and natural method of conſidering the ſubject appears to me to be preferable to the more laboured arrangements founded on the eſſential nature and chemical compoſition of the fluids, becauſe it is not expoſed to that uncertainty, which the imperfection, the variations, and even the progreſs of our knowledge concerning the nature and properties of animal matters, muſt unavoidably occaſion. It is, moreover, the moſt eaſy and inſtructive way to conſider the ſecreted fluids in their relations to the ſolid organs, with whoſe functions they are concerned. The diſtribution of the animal fluids with regard to the ſeven organic ſyſtems of which the human body is compoſed, will be better underſtood by preſenting it in a tabular view, where their relations, influences, and uſes, will be immediately perceptible.

Fluids of the nervous or ſenſitive ſyſtem.	Fluid of the ventricles of the brain, Aqueous, vitreous, and cryſtalline humours of the eye, Tears, Meibomian ſecretion, Mucus of the noſe, Cerumen, Fluid of the labyrinth of the ear, Saliva.
Of the muſcular or moving ſyſtem.	Fibrine, Seroſity, Fat.
Of the vaſcular or calorific ſyſtem.	Mucus of the trachea and air-veſſels, Fluid of the pericardium, ——— pleuræ, Pulmonary exhalation, Blood.
Of the viſceral ſyſtem or organs of ſupply.	Mucus of the mouth, pharynx, and œſophagus, ——— ſtomach, ——— inteſtines, ——— kidney and bladder, Gaſtric fluid, Pancreatic fluid, Inteſtinal fluid, Exhalation of the abdominal cavity, Bile, Liquor of the renal capſules, Urine.
Of the lymphatic or collecting ſyſtem.	Reſidue of all the fluids, and of nutrition, Lymph, Fat of the cellular tiſſue, Mucous fluid.
Of the ſexual or reproductive ſyſtem.	Proſtatic liquor, Mucus of the urethra, ——— vagina, Seminal fluid, Exhalation of the tunica vaginalis, Contents of the ovarian veſicles, Liquor amnii; Meconium.
Of the bony or ſupporting ſyſtem.	Gelatine, Medulla, Synovia.

Of the fluids juſt mentioned, ſome are ſecreted in certain organs belonging to their reſpective ſyſtems; *e. gr.* thoſe of the conglomerate glands, of the glandular viſcera, &c.; others are formed over whole organic ſyſtems, without any particular apparatus, as the exhalation in the cellular membrane, that of the circumſcribed cavities, &c.; while others are not the produce of ſecretion, but move freely through all parts of the ſyſtem in which they are concerned, as the blood and contents of the abſorbing ſyſtem. With the latter we have nothing to do at preſent; neither does the organization, from which the fluids of the middle claſs are produced, come under our conſideration in this article, but it will be deſcribed in INTEGUMENTS, MEMBRANE, and CELLULAR SUBSTANCE.

The phyſiological theory of the ſecretions muſt be founded on a perfect knowledge of the nature of the animal fluids, and of the ſtructure of the ſecretory organs. The ſolution of the intereſting problems ariſing out of this ſubject, can be expected only from the union of anatomy, enlightened by juſt views of phyſical ſcience, with chemiſtry, ſupported and directed by phyſiological obſervation. The ſecretory organs are of various kinds, and preſerve a conſtant relation to the kind of ſecretion, and the manner in which it is effected. Thoſe fluids, which ſeem to be derived from the blood, with the leaſt change, are not produced by a complicated organic apparatus. The exhalation, which moiſtens the ſurfaces of the circumſcribed cavities, the aqueous vapour of the lungs, and the cutaneous perſpiration are formed by organic ſyſtems, compoſed chiefly of vaſcular ramifications, without poſſeſſing any thing that is at all analogous to glandular ſtructure. The arrangement of the fibrous tiſſue of muſcles, and of the bony fabric, admit of the ſame remark; if we ſuppoſe that theſe organs habitually ſecrete fibrine or bony matter. But theſe are caſes, which come under the deſcription of nutrition, and in this ſenſe all parts of the body may be called ſecretory organs,

gans. The mucous fluids, which appear to differ more conſiderably from the materials in the blood, are generally ſeparated by particular glands, which are called crypts or follicles, contained in the ſubſtance of the membranes or viſcera. But it ſeems probable, that theſe alſo may be ſeparated from the vaſcular ramifications of a ſimple membranous tiſſue without any expreſs glandular ſtructure, as in the caſe of ſeveral mucous membranes. It remains therefore for us at preſent to explain, in a general way, the anatomical ſtructure of the various glands, by which the other animal fluids are ſecreted.

The glandular differs from moſt other ſyſtems, in the animal economy, in this circumſtance, that its peculiar tiſſue is not exactly identical in all the organs belonging to it. The fibres of any voluntary muſcle would ſerve equally well to compoſe any other of the ſame kind. Tendinous fibres, cartilaginous and bony ſtructures, are the ſame every where. The ſubſtance of the liver, on the contrary, is widely different from that of the kidney; which again is very diſtinct in its character from that of the ſalivary glands. The glandular ſyſtem, therefore, is marked in its various parts with very few general attributes, which alſo ſuffer many exceptions.

Situation, forms, diviſion, &c. of the glandular ſyſtem.—Glands have two different ſituations in the body. Some are ſubcutaneous, as the breaſts and ſalivary glands; others deeply ſeated, as the liver, kidnies, pancreas, and moſt of the mucous glands, and conſequently, not expoſed to the action of the external bodies. Many of them occupy ſituations where there is much motion, as the ſalivary glands near the jaw, the mucous in cloſe contact with a plane of muſcular fibres, the liver in the vicinity of the diaphragm, &c. Theſe facts have led to the ſuppoſition that the neighbouring motion, extraneous to their functions, determined the excretion of the ſecreted fluids. But, in the firſt place, the palatine glands, the pancreas, the teſticles, and even the kidnies, are ſo ſituated, as to be out of the way of ſuch external aſſiſtance. And we obſerve, further, that mucus is ſecreted as abundantly by the pituitary membrane, as in any other part, although there is no muſcular plane here; that the lining of the bladder produces an equally copious ſupply, when the viſcus is paralytic; and that various cauſes augment the ſecretions, without any connection with the circumſtance firſt alluded to, as ſialagogue medicines, or the ſight of food in the caſe of ſalivary glands. We cannot doubt, therefore, as Bordeu has obſerved, that this mechanical cauſe has nothing to do with the matter, and that the eſſential cauſe of all excretion conſiſts in a peculiar vital action.

Some glands are ſingle, as the liver and pancreas; others are arranged in pairs, as the kidnies, ſalivary, and lacrymal glands. The latter are ſimilar on both ſides of the body; but the reſemblance cannot be compared, in reſpect to its exactneſs, to that of the double organs in the animal life. One kidney is lower than the other; their arteries, veins, and nerves, are not analogous in length or ſize; often various notches exiſt in one, and not in the other: the ſame obſervations will apply to the ſalivary glands.

Generally the forms are not determined in a very certain manner in this ſyſtem: they are ſubject to innumerable modifications in volume, direction, and the different proportions; and differ remarkably, in theſe reſpects, from the preciſe and rigorous laws which govern the conformation of the organs of animal life. Take ſome one organ, by way of example, from both lives. A ſmall brain will be found to poſſeſs a corpus calloſum, thalami optici, and corpora ſtriata of correſponding ſize; while, on the contrary, a large liver often has a ſmall lobulus Spigelii, and *vice verſâ.* A kidney will often be larger in its upper portion only, or in the lower. Theſe variations in the animal life affect the whole organ: while they frequently are obſerved in ſome part only in the organic. Bichat, who makes this remark, endeavours to explain the fact, by his opinion concerning the neceſſity of a harmony of action in the animal life. If one ſide of the brain were developed more than the other; if one eye, one ear, or one ſide of the noſe exceeded the correſponding organs, the operations of the mind, the ſenſe of ſight, hearing or ſmelling, would be inevitably diſturbed: while the ſecretion of bile or urine would go on equally well, although ſome particular part of the ſecreting organs were proportionally larger or ſmaller than the others. The glands, which are ſurrounded by membranes, as the liver, kidnies, and even the pancreas, are leſs ſubject to theſe variations of figure, than thoſe which are contained in the cellular ſubſtance, without any membranous covering, as the ſalivary, lacrymal, mucous glands, &c. Thoſe of the latter deſcription in the mouth, and along the trachea, are never alike in two ſubjects. The parotid ſometimes is prolonged over the maſſeter, and at others leaves that muſcle uncovered; varies in its breadth, &c. When either of a pair of glands is ſo diſeaſed, as to be incapable of continuing its function, that on the oppoſite ſide of the body either increaſes in bulk, as we may ſometimes obſerve in the kidnies; or its ſecretion is augmented.

The ſurface of ſuch glands as are not covered by membranes is uneven and tuberculated; it may be in contact with muſcles, veſſels, nerves, &c. even with bones, as in the ſalivary and lacrymal glands. In general, they are ſurrounded by leſs cellular tiſſue, than organs which have conſiderable motion. That which is in immediate contact with them is denſe, like the exterior covering of arteries and veins, but it is not ſo firm. It does not uſually contain fat; and by iſolating the gland to a certain degree, it is analogous to the peritoneal covering of the liver, or to the proper membrane of the kidney or ſpleen. Anatomiſts have very commonly divided the glandular ſyſtem into the conglobate and conglomerate glands. The former name denotes the gland-like bodies belonging to the lymphatic ſyſtem, and was deſigned to ſhew that each formed only one maſs. The latter term is moſt properly applied to the ſalivary and lacrymal glands and pancreas, which are made up of numerous ſmaller particles united together. It cannot well be given to the liver and kidnies, which poſſeſs nothing of a conglomerate ſtructure; and theſe, accordingly, have been generally called glandular viſcera.

Organization of the Glandular Syſtem.

1. *Peculiar tiſſue of this ſyſtem.*—The glandular tiſſue differs from moſt others, in poſſeſſing no marks whatever of a fibrous diſpoſition. Its component elements are not placed by the ſide of each other, according to longitudinal or oblique lines, as in the muſcles, the fibrous ſyſtem, the bones, nerves, &c.; but they are heaped together, by a kind of confuſed, and, as it were, caſual approximation, and adhere together but weakly. Thus, while organs, which poſſeſs diſtinct fibres, have conſiderable powers of reſiſtance, particularly in the direction of their fibres, glands are torn eaſily by ſlight degrees of violence. The broken ſurface is uneven, full of projections and depreſſions, which diſtinguiſh theſe organs from cartilage; the rupture of which is generally ſmooth. The proſtate, tonſils, and mucous glands reſiſt much more powerfully than the liver and kidnies, in which the phenomenon juſt mentioned is the moſt eaſily obſervable. The pancreas and ſalivary glands are elongated by any diſtending force, without tearing; but this circum-

ſtance ariſes from the abundant cellular tiſſue diſtributed throughout their ſubſtance, and not from any peculiar property of their glandular tiſſue. Their lobes are ſeparated in proportion as the intermediate cellular filaments are elongated.

The glandular tiſſue, which anatomiſts have generally called *parenchyma*, is diſpoſed in three different ways. 1. In the ſalivary, lacrymal, and pancreatic glands, which are properly called conglomerate, the organ is made of diſtinct portions, connected together by a looſe and copious cellular texture, the intervals of which tranſmit veſſels and nerves. Theſe are again made up of ſmaller lobes united in the ſame way; and the diviſions are more eaſily purſued when water has penetrated into the connecting ſubſtance. Repeated diviſions ſhew us ſmaller and ſmaller component portions, till we come at laſt to very ſmall bodies, ſtill conſpicuous to the naked eye, and called glandular acini (grains glanduleux, Fr.) Theſe component parts are firmer in proportion to their ſmallneſs, as they are ſurrounded and connected to the adjoining portions by ſhorter and firmer cellular ſubſtance. We can eaſily follow the 2d, 3d, and even the 4th diviſion of theſe lobes with the ſcalpel. The acini are of a roundiſh figure and pale colour, and diſtinguiſhable from any thing of a muſcular nature by the abſence of fibres. When examined with magnifying glaſſes, they are ſeen divided into ſmaller portions by cellular interſtices, and we can hardly come to an end of theſe diviſions, if we employ ſucceſſively greater magnifying powers. 2. There are no traces of the primary diviſions juſt deſcribed, into the larger and ſucceeding lobes, in the liver and kidnies. They conſiſt of an uniform and even tiſſue made up of glandular acini, cloſely united together into one ſubſtance. The connecting cellular ſtructure of theſe particles, if there be any, is very ſmall in quantity and ſhort; hence the facility with which theſe bodies may be torn, and the kind of granulations which their rupture preſents. 3. The proſtate, tonſils, and all the mucous glands, have no appearance either of primary or ſecondary lobes or acini. The firſt of theſe conſiſts of a denſe parenchyma: the latter of a ſoft and almoſt pulpy ſubſtance. They cannot be torn, like the liver and kidnies.

Controverſy concerning the ſtructure of the glandular acini.—It is eaſy to proceed thus far in analyſing the compoſition of the glands; but theſe reſearches do not at all contribute to explain the mechaniſm of ſecretion. In the hope of accompliſhing that object, anatomiſts began, as ſoon as the improved condition of the ſcience furniſhed the means of proſecuting ſuch inveſtigations, to ſubject the various ſecretory organs to a very attentive and cloſe examination, and endeavoured to ſhew the nature of the acini, into which moſt of the glands were ultimately reſolvable. The aid of magnifying glaſſes, and of anatomical injections, was reſorted to on this occaſion; but the opinions of two individuals, who had devoted much time to the ſubject, were completely at variance, and gave riſe to a controverſy, which had at leaſt this good effect, that it occaſioned a very thorough examination of the ſubject. Malpighi taught that the acini are hollow; that the arteries diſtributed on their ſurface depoſit the ſecreted fluid in their cavities, and that it is conveyed thence by an excretory duct; that the union of theſe tubes forms larger excretory canals, &c. He deems the mucous glands of the alimentary canal, mouth, &c. to be the moſt ſimple forms of glandular ſtructure, and conſiders that the larger glands differ only in conſiſting of an aggregation of ſuch ſimple ones. "Glandula, qua palatum, œſophagus, inteſtina, et conſimiles partes copioſe ditantur, eſt omnium ſimpliciſſima, et idea reliquarum glandularum. Hæc itaque folliculo membranoſo ſeu loculo conſtat, qui ovali, interdum rotunda, quandoque lenticulari, vel oblonga conſtat forma; concavitate pollet, quæ ut plurimum in vaſculum excretorium aperitur, quo ſeparatus humor in peculiarem capacitatem, vel foras extra pellitur. Circa loculum ſeu folliculum vaſa ſanguinea et nervi diramantur, et ut conjectura aſſequi licet, carneæ fibræ circumducuntur, vel ſaltem ſub plano extenſi muſculi locantur, ut in ventriculo, et œſophago patet. Huic proximæ ſuccedunt glandulæ, majori loculorum numero ditatæ, quales ſunt in facie, in labris, in quibuſdam cutis partibus, circa pudendum et palatum: excretorio namque vaſculo, interdum oblongo multiplices appenduntur loculi membranoſi in ipſum hiantes, circa quos ſanguinea vaſa et nervi ramificantur." Epiſtola Reg. Soc. Londin. Dicata, in Opp. Poſthum.

In the Exercitationes de Structura Viſcerum, he endeavours to prove that the larger glandular bodies are formed on the ſame principles with the parts juſt alluded to. He examines the liver by removing the external membrane, macerating it in water, boiling, &c. and employs the microſcope. "In compingendo itaque hepate talis videtur firma naturæ methodus: vaſa in ramos hinc inde diſperguntur; ad ſingulas autem vaſorum propagines, licet etiam exiles, lobuli appenduntur, conicam ut plurimum ſervantes figuram: conſimilem etiam in pancreate, cæteriſque conglomeratis glandulis obſervamus.—Glanduloſi acini, quibus lobulus componitur, cum peculiarem circumſcriptionem habeant, neceſſario propria et ipſis figura, quæ ut plurimum hexagona, vel plurium laterum eſt: hinc etiam neceſſe eſt, ut ad invicem, præter vaſorum ramos, peculiaribus membranoſis vinculis nectantur, et interſtitia aliqua emergant, quæ in piſcibus et imperfectioribus magis conſpicua ſunt, in perfectioribus autem obſcurantur. Ad ſingulos autem, hoſque minimos lobulos, multiplices vaſorum rami derivantur. Tota jecoris moles ex his duobus coaleſcit, glanduloſis ſcilicet acinis, et diverſis vaſorum propaginibus; quare, ut aliquod ex his commune opus emanet, neceſſe eſt, ut inter glandulas et vaſa commercium intercedat." Exercit. Anat. de Hepate, cap. 2. He deſcribes ſimilar acini as exiſting in the kidnies, ſpleen, and cortical ſubſtance of the brain. And he defends his opinions on this ſubject in general, by arguments drawn from various ſources, as the appearances of diſeaſe, &c. which cannot be allowed to prove much on either ſide.

The opinion oppoſed to that of Malpighi, conſiders all the viſcera and glands to conſiſt of veſſels and cellular ſubſtance, without any membranous cavities interpoſed between the arteries and the excretory ducts. This doctrine was particularly ſupported and extended by Ruyſch, who, although he was not remarkable for quickneſs or learning, exceeded moſt of his contemporaries in his opportunities of diſſection, which were very ample, and continued for nearly eighty years, and in the art of injecting and preparing the organs of the body in various ways. His obſervations carried the greater weight, becauſe he was averſe to hypotheſes, and taught only what he ſaw. In his youth he admitted, with other anatomiſts, the glandular acini of the viſcera. But, when he found, as he proceeded in his anatomical labours, that membranes, naturally perfectly white, exhibit innumerable veſſels after injection, that the ſubſtance of the viſcera is filled almoſt entirely with injected fluids, and may be reſolved into a mere vaſcular contexture by maceration in pure water, he gradually changed his opinion, and began to teach that the viſcera and the conglomerate glands, and even moſt of the ſimple ones, are compoſed entirely of veſſels, from which the excretory tubes are continued without any intervening medium. Injections in the dead body ſeem to prove the latter circumſtance, as fluids in ſome inſtances paſs very readily from the blood-veſſels into the excretory ducts; *e. gr.* in the kidney and liver. As Ruyſch continued his inveſtigations, he found that the bodies conſidered as glandular and hollow acini by Malpighi, are mere blood-veſſels. After accurately injecting the liver and kidney, and macerating them in water, he found them reſolved into ſmall cluſters of blood-veſſels, and proved this ſo clearly by his preparations, that Boerhaave, who had been a warm defender of Malpighi's doctrine, in defence of which he wrote the Epiſtola de Fabrica Glandularum, ad F. Ruyſch., was induced to renounce his opinion. The elegant preparations of Ruyſch, and his appeal to the evidence of diſſection, and other anatomical inveſtigations, brought moſt anatomiſts over to his opinions, which, indeed, are generally received in the preſent day. Haller gives the following ſummary of his opinions on this ſubject. "Viſcera nempe ſecretioni deſtinata, eorumque imprimis acinos, glandulaſque conglomeratas, meris componi vaſculis, celluloſæ telæ ope conjunctis, eo cum vinculi robore ut conſiſtat acinus, aque ſui ſimilibus, laxioribus filis ſibi annexis, totus et integer deduci poſſit. In quolibet præterea acino, vaſorumve glomere, ex eadem ſententia, ductus excretorius eſt, pluresve ductuli, qui de arteriola minima, tanquam ramulus minor et ſanguini impervius, decedere videtur, quæ fabrica in rene certo reperitur, in aliis quidem colis magna cum veri ſpecie ex conjectura admittitur. Secretio adeo a vulgari ſanguinis circuitu hactenus differt, quod in iſta quidem arteriola minima cylindrica, in venam ſibi æqualem, aut ampliorem continuetur, quæ ſanguinem recipere apta ſit, in humorum vero ſeparatione ductus excretorius, rubro vaſculo arterioſo minor, tanquam ramus ex eo vaſculo prodeat." Element. Phyſiolog. lib. 7. ſect. 2. § 14. The opinions and arguments of Ruyſch may be collected in his anſwer to the letter of Boerhaave mentioned above, in ſome of his other epiſtles, and in various of his Theſauri. He has given ſeveral figures repreſenting the diſtribution of the minute veſſels in various organs, and proves ſatisfactorily that the bodies called acini by Malpighi are merely minute veſſels: he ſhews this concerning the ſpleen and brain, as well as in the glandular viſcera. On the ſubject of this controverſy, we may obſerve, that its importance does by no means warrant the pains beſtowed on it, and the noiſe made by the combatants in conducting it. The nature of the inveſtigation, which is carried on entirely in the minute elements of the body, and proſecuted by means of magnifying glaſſes, injection, maceration, and corroſion, renders the concluſions, which we arrive at, in great meaſure, uncertain; and the parts, of which the ſtructure is ſought, are ſo exceedingly ſmall, that neither opinions can be conſidered as clearly demonſtrated, or ſatisfactorily refuted. The mode, in which ſecretion is effected, is equally obſcure, whichever of the two ſuppoſitions we may adopt: neither of them ſolves the myſtery. Let us admit with Ruyſch that the excretory tube is continuous with the ſecreting artery; ſhall we then underſtand how ſuch infinitely diverſified products, all differing from each other, and from the blood, are formed from the common maſs of that fluid? Shall we be able to point out the preciſe ſpot in the continuous canal where the blood ends, and the bile, urine, or milk begins? and to explain *how* the change is effected? If, on the contrary, we ſuppoſe, with Malpighi, that arteries, ramifying on ſmall membranous cavities, depoſit the new products in thoſe receptacles, our ignorance of the points in queſtion is neither more nor leſs complete than in the other caſe. Too much labour has been already ſpent on theſe idle diſquiſitions; modern anatomiſts have judged wiſely in abandoning them, and in preferring the taſk of collecting facts concerning the natural and diſeaſed ſtructure and functions of our frame.

With ſuch impreſſions, concerning the value of theſe purſuits, we were much diverted, at obſerving the complacency with which Ruyſch, the great authority of the two laſt centuries on the ſtructure of glands, contemplates his own doctrines, and the ſang-froid with which he repreſents his own diſcoveries, as the immediate produce of a direct divine revelation. "Placuit bonitati divinæ hæc revelare meis laboribus jam ſenilibus. Invidi, et inimici mei hæc ridebant in initio, ſed Deus cui ſoli omnis gloria et honor, hæc ita benedixit poſtea," &c. Epiſtola Anatom. ad v. c. H. Boerhaave.

The organization of all the glands is by no means ſo uniform as to admit of our referring the mode of glandular ſecretion to any one mechaniſm. The mammary gland and teſtis do not reſemble the texture of the organs already deſcribed. In both of theſe, which again are widely different in all their ſenſible properties from each other, there is a vaſt congeries of ſecretory tubes, infinitely convoluted, with vaſcular ramifications copiouſly diſtributed among them. In the ultimate elementary parts of theſe glands, as far as our ſenſes can purſue them, we diſcover nothing but minute, ſerpentine, and very ſlender tubes; which are particularly obvious in the teſtis, without any trace of Malpighian or Ruyſchian acini. In the breaſt, indeed, the exiſtence of theſe bodies has been a matter of diſpute, and arguments, not deficient in plauſibility, have been adduced on both ſides of this important queſtion, which, like many religious myſteries, is involved in juſt ſo much obſcurity, as to make it a very ſuitable ſubject for polemical exercise.

The organs of the mucous ſecretion, in general, do not fall within the deſcription already given of the glandular ſtructure. Theſe ſeem to exhibit, in many inſtances, a very ſimple form of gland, of which, however, the action is no more underſtood, than that of the more complicated kinds. They conſiſt of ſmall receptacles, lined by the membrane covering the part, receiving the ſecretion, and pouring it out by a ſingle orifice in the centre. Very ſimple glands of this kind are ſeen at the root of the tongue: their figure is circular or elliptical; the cavity is lined by a thin membrane, ſurrounded by a pulpy vaſcular ſubſtance, which cauſes a ſuperficial prominence, in the centre of which is a ſimple aperture, affording mucus on preſſure after death.

In other inſtances, the membranous part is more conſpicuous, and the glandular ſubſtance leſs conſiderable, or indeed hardly perceptible, ſo that the whole ſeems to be formed merely of membrane. Theſe have been called cryptæ, folliculi, &c. Their figure is generally circular or oval, and they are lined by continuations of the membrane, to which they belong. They are placed in the cellular ſubſtance, and may poſſeſs more or leſs of the pulpy vaſcular matter. They have ſimple excretory tubes, commencing from the hollow of the membranous cavity, and terminating by open orifices on the ſurface of the part to which they belong, as the mouth, fauces, trachea, or inteſtines. Preſſure forces the ſecreted mucus from the open orifice. To this claſs may be referred the glands of the lips, cheeks, epiglottis, pharynx, and œſophagus, thoſe of the ſoft palate, trachea, ſtomach, and inteſtines.

Theſe more ſimple kinds of crypts or follicles are united in different inſtances, ſo as to compoſe larger maſſes. Sometimes they are ſimply contiguous, connected by looſe cellular ſubſtance, and poſſeſs each its proper duct: *e. g.* at the back of the tongue, and about the arytenoid cartilages. Such have been called glandulæ congregatæ. In other inſtances, numerous follicles, included in a common covering, depoſit their mucus in one or more large cavities, into which ſeveral follicles open. The tonſils afford an example, and have been called glandulæ conglutinatæ.

The ſecretion of mucus is often performed in a ſpecies of ſtructure, which does not ſeem to poſſeſs any thing of a glandular nature: in ſmall membranous canals, which will admit briſtles for about half an inch in length, ending by blind extremities in the cellular ſubſtance, and terminating by oblique apertures on the ſurfaces of the mucous membranes to which they belong. Neither acini nor round follicles can be diſcovered opening into ſuch canals, which are technically named ſinuſes or lacunæ, and which, in the urethra, have a perfectly ſmooth ſurface. Some of theſe are ſimple, as in the ſeptum narium, the urethra of both ſexes, the entrance of the vagina, &c.; others are ramified, as in ſome inſtances in the male urethra; in the neck of the uterus, &c.

The glands, which produce various matters of an unctuous deſcription, appear to be very ſimple in their ſtructure, but they are moſtly ſo ſmall as to prevent us from entering into much detail concerning their organization. The ceruminous glands of the ear are ſmall round bodies, diſperſed in the interſtices of the cellular ſubſtance, and each of which poſſeſſes a duct, penetrating the integuments of the meatus auditorius, and ending on its ſurface by an open mouth. They ſeem to conſiſt of ſimple membranous cavities. The organs, which ſecrete ſebaceous matter, in various parts of the integuments, do not ſeem to differ eſſentially from theſe. They are round membranous cavities, with their ſides covered by numerous vaſcular ramifications, opening on the ſurface of the part to which they belong, with or without the intervention of a ſimple duct. Where they produce a fluid which concretes, it may be expreſſed from them in the form of a ſlender white thread. The areola of the nipple, the nymphæ, and the other external female organs, the corona glandis of the male, the noſe, and particularly the cavity between its ala and the cheek, the upper lip, and the hollows of the external ear, poſſeſs numerous glands of this deſcription. The Meibomian apparatus of the eye-lids is only a rather complicated ſpecimen of the ſame ſtructure; ſeveral ſimple glands open into a common duct.

The proſtate poſſeſſes a peculiar ſtructure, which can hardly be referred with propriety to any of the ſpecies firſt enumerated.

The glandular tiſſue, cut in ſlices and dried in the air, loſes its original colour, acquires a dark hue, and even a blackiſh tint in the liver and kidney, on account of the large quantity of blood which they contain: if the latter viſcera are repeatedly waſhed, before they are dried, they continue to appear greyiſh. The glandular tiſſue, in its dried ſtate, is remarkably hard and brittle. If kept moiſt and expoſed to the air, it becomes putrid very rapidly, and exhales in that ſtate a highly diſagreeable odour. A greater quantity of ammoniacal matter is formed. The liver is particularly diſtinguiſhed for the inſupportable ſtench cauſed by its putrefaction. The kidney goes leſs rapidly into that ſtate. When boiled, the glandular ſubſtance produces at firſt a greyiſh ſubſtance, which troubles the water uniformly at firſt, and is then collected in an abundant froth at the top. This product is moſt abundant in the preſent, the muſcular, mucous, and cellular ſyſtems; and leaſt in the cartilaginous, tendinous, fibrous, &c. The froth produced by its boiling is of a deeper colour, and ſeems to contain more numerous principles, than that derived from the white organs.

Like all other ſyſtems, the glands grow hard at the firſt periods of ebullition, but inſtead of becoming ſofter afterwards, as the others do, the continued boiling makes them more and more hard; ſo that after five or ſix hours of ebullition, their firmneſs is triple or quadruple that which belongs to them naturally. This phenomenon is moſt remarkable in the liver. When removed immediately after the firſt corrugating effects of the hot water, they do not diſplay the elaſticity which the other ſyſtems poſſeſs at this time. A tendon or muſcle in ſuch a ſtate, if drawn, reſtores itſelf immediately, while a ſlice of liver breaks. The abſence of fibrous matter perhaps is the real cauſe of this difference. The ſudden action of naked fire criſps and corrugates the ſurface, as in all the other ſolids, and produces a hard exterior cruſt.

Maceration in water produces different effects on the different glands. The liver reſiſts longer than the kidney, which, after two months, is reduced to a reddiſh pulp ſwimming in the water, while the former ſtill preſerved its form and denſity, and had undergone no other change than from a red to a blueiſh brown colour. The ſalivary glands exhibit much of the whitiſh, unctuous and firm matter, which is ſeen in all cellular organs after long maceration. This does not ariſe from an alteration of the glandular tiſſue, but from the fat contained in the abundant cellular texture of theſe parts.

Acids act on the glandular tiſſue nearly as upon the others. They reduce it into a pulp, varying in its colour, and in the promptitude of its formation according to the nature of the acid employed. The ſulphuric acts moſt quickly, and gives a black pulp, while the nitric renders it yellow. They act much more ſlowly on the glands after boiling than before.

Generally ſpeaking, the glands are much leſs digeſtible than moſt other animal ſubſtances; particularly in their boiled ſtate: for coction produces in them quite oppoſite effects to thoſe which it exerts on the cartilages, tendons, and all the fibrous organs, which are rendered leſs denſe, more gelatinous and viſcous, and more ſpeedily diſſolvable by the gaſtric juice. The glands would probably be digeſted more eaſily, if eaten raw. Liver is leſs digeſtible in proportion as it is longer boiled. Bichat made a comparative trial of it in a raw and dreſſed ſtate: the former was reduced into a pulp in the ſtomach of a dog, when the latter had undergone a very ſlight alteration.

Excretory tubes.—All glands have tubes for the purpoſe of conveying away the fluids, which they ſeparate from the blood; and as theſe canals are only found in glands, their conſideration belongs to that of the peculiar tiſſue of the gland. The excretory ducts have an uniform origin in all glands. They ariſe like veins, by an infinite number of capillary tubes, which appear to begin at the acini, where theſe exiſt. Each acinus is ſaid to have an arterial and venous, as well as an excretory tube. Ariſing in this way from all the interior of the gland, they ſoon unite together, into more conſiderable tubes, which generally run in ſtraight lines through the glandular tiſſue, unite to each other, and form at laſt one or more large tubes.

Glands are to be diſtinguiſhed into three kinds, with reſpect to their excretory tubes. 1. Some tranſmit their ſecretion through ſeveral ducts, each formed by ſmaller ones, and opening near together, but diſtinctly, and without any communication. In ſome caſes theſe ſeparate apertures are found on a more or leſs diſtinct prominence, as in the breaſt, proſtate, and ſublingual glands. Sometimes the orifices are found in a depreſſion, in a kind of cul-de-ſac, as in the tonſils, the foramen cæcum of the tongue, &c. 2. Other and more numerous glands pour out their fluids by a ſingle tube, and there is nothing remarkable in general in the orifice. 3. Some glands depoſit the produce of their ſecretion in a reſervoir, where it is retained, in order to be expelled at particular times. Such are the kidnies, liver, and teſticles. In this caſe there muſt be two excretory tubes; one to convey the ſecretion from the gland to the reſervoir, and the other to tranſmit it to its final deſtination.. Theſe reſervoirs are therefore evidently connected with the excretory tubes.

Although the two firſt claſſes of glands have no reſervoirs, we may in ſome degree regard the different ramifications of their excretory tubes as ſupplying their place. Theſe, indeed, as well as in the glands, which have reſervoirs, are habitually full of the ſecreted fluid. Under whatever circumſtances the individual may have died, we may always produce a conſiderable flow of proſtatic fluid by preſſure on the gland. The papilla of the kidney affords urine on the preſſure, ſections of the liver ſhew bile in the hepatic ducts, and the lactiferous veſſels are full of milk, for which there is no other reſervoir. From variations in the quantity of fluid, in the latter inſtance, the greater or leſs ſize of the breaſt, during ſuckling, entirely depends.

It appears in general that the paſſage of the ſecreted fluids in the excretory ducts is much ſlower than that of blood in the veins, or of lymph in the abſorbing veſſels. Urine is conſtantly flowing through the ureters; but a much greater proportion of blood would paſs through a vein of equal diameter, while the bladder was filling. The rate of motion however varies under different circumſtances, the ſaliva is excreted much more quickly during a meal, and urine paſſes off much faſter after watery drinks.

The ſize of the excretory tubes varies very conſiderably. 1. Where ſeveral are produced from one gland, they are very ſmall, and ſometimes ſcarcely perceptible. They run in a ſtraight line, have no communications, and open immediately on quitting the gland. 2. Thoſe which are ſingle are larger; bearing a proportion however to the ſize of the gland, excepting the hepatic duct, which is manifeſtly very ſmall in compariſon to the bulk of the liver. They paſs for ſome diſtance after quitting the gland, and are produced by the union of ſuch tubes as belong to the laſt mentioned claſs; ſo that if their iſolated excretory tubes were to be united together, a common ſingle duct would be formed reſembling thoſe of this ſecond kind. The pancreas is the only inſtance in which the common duct is concealed in the ſubſtance of the gland: and there is no other inſtance, but the teſtis, where it forms convolutions, ſo as to be much longer than the courſe through which it paſſes.

Whatever the arrangement of the excretory tubes may be, they all pour their fluids either on the ſurface of the body, as in the ceruminous and ſebaceous glands, and the breaſt; or on the ſurface of mucous membranes, as the mucous, ſalivary, pancreatic and hepatic excretories. The ſkin and mucous membranes, therefore, are the only parts moiſtened by glandular fluids; no ducts terminate on ſerous or ſynovial ſurfaces. The excretories of the pretended articular glands would form an exception to this obſervation, if the glands exiſted. They never terminate in the cellular membrane; and if a communication ſhould take place, by accident, abſceſſes are formed by the ſupervening irritation, as in urinary fiſtulæ: or inflammation occurs in the track of the extravaſated fluid, producing adheſions, which preſerve the cellular ſyſtem from more extenſive infiltration. Thus the alimentary canal may be regarded as a kind of general excretory, ſuperadded to thoſe of the liver and pancreas, &c., and expelling in one maſs all the fluids ſeparately poured through their reſpective ducts into its cavity. Indeed, all ſecreted fluids ſeem deſigned to be thrown out of the body. Separated from the maſs of blood, they are heterogeneous to it, and do not enter the general circulation again in a ſtate of health.

All the excretory ducts have an internal mucous membrane, which is a continuation of the cutaneous or mucous ſurface, on which they terminate. In addition to this they all poſſeſs an exterior ſubſtance, including the mucous canal, and differing conſiderably in the particular glands. It is a very thick and peculiar ſubſtance in the vas deferens: an extremely denſe and cloſe texture, reſembling that of the arteries and veins in the hepatic and ſalivary tubes, &c. The latter is very different from ordinary cellular ſubſtance. It does not appear that theſe tubes poſſeſs any membrane beſides the tiſſue juſt deſcribed, and the mucous lining. Every excretory tube has its blood-veſſels. The ureters receive very manifeſt arterial branches from the renal and ſpermatic arteries: the hepatic artery ſupplies the biliary tubes, and the Stenonian duct has its branches from the tranſverſalis faciei. Various nerves from the ganglia accompany the blood-veſſels; but they never form ſuch intricate plexuſes as round the arteries.

The excretory ducts poſſeſs chiefly the vital properties of the mucous ſyſtem, which has the greateſt ſhare in their formation. Their ſympathies are, therefore, nearly of the ſame kind.

2. *Of the other Syſtems belonging to the formation of the Glands.*

Cellular ſubſtance.—Glands differ much in the proportion of this tiſſue, which they contain, and may be divided accordingly into two claſſes. It is very abundant in the ſalivary organs, in the pancreas, and lacrymal gland, and in all ſuch as have a conglomerate or granulated ſtructure and white appearance. Every gland of this claſs is divided into lobes very diſtinctly iſolated by grooves filled with this texture, and determining the tuberculated ſurface which characterizes the exterior of the organ. Each lobule, and every glandular acinus, down to the ſmalleſt diviſion, is covered by cellular ſubſtance: hence the whole conſiſts of an aſſemblage of ſmall diſtinct bodies, connected together only by the circumſtance of their excretory tubes being united to form a common duct, and which we could conceive to be perfectly capable of exerciſing their functions if actually ſeparate. We ſee this in the parotid; where ſmall acceſſory portions are often ſeen in the courſe of the duct, completely unconnected with the principal gland. The ſubmaxillary and ſublingual are ſometimes continuous, ſometimes iſolated. The cellular tiſſue in theſe glands often contains an abundance of fat. This is particularly obſervable in the breaſt, the volume of which ſometimes depends on the ſize of the gland, ſometimes on an accumulation of the adipous ſubſtance; a difference, which is very eaſily recognized by the touch. Hence the quantity of milk is not always in proportion to the apparent ſize of the mammæ. In the proper conglomerate glands, however, the adipous ſubſtance ſeldom amounts to a very conſiderable quantity. The connecting threads are very ſhort and ſlender in the teſtis. In thoſe glands, which have a denſe parenchyma, as the liver, kidney, proſtate, and mucous organs, there is very little cellular tiſſue, and hence the facility with which ſome of them may be torn. Their ſubſtance never contains fat. The unctuous ſtate of the liver in various diſeaſes does not invalidate this obſervation; for the fat then enters into its compoſition as an eſſential element of the organ, and is ſubſtituted in place of the colouring matter, which diſappears; it is not contained in cells. Fat may be ſeen alſo in the interior of the kidney, but it is round the pelvis, and not in the proper parenchyma of the gland. The tonſils, proſtate, and mucous glands never contain any. Serous fluids are never thrown out in the ſubſtance of glands, which have a cloſe parenchyma; they are not affected in caſes of the moſt general and extenſive anaſarca. We cannot, however, doubt the exiſtence of cellular tiſſue in ſuch glands: maceration demonſtrates it. The fungous tumours, growing from theſe organs, contain much of it; and it is principally ſeen round the veſſels, as in the capſula Gliſſoni. This texture, indeed, is often diſeaſed, while the proper ſubſtance of the gland remains

ſound:

found: hence the developement of ſteatomatous tumours in the liver, of ſerous cyſts in the kidnies, and of hydatids in both, without the ſecretion being at all diſturbed. The liver is ſometimes encreaſed three or four-fold by internal tumours, without its proper tiſſue being augmented: the latter forms a kind of ſepta between the ſwellings in which the biliary ſecretion goes on.

Blood-veſſels.—Glands, which are not ſurrounded by a membrane, receive their arteries from all quarters. An abundance of ſmall branches from the neighbouring trunks penetrates the ſurface of the ſalivary and lacrymal glands, the pancreas, &c. They firſt run between the lobes, penetrate into the ſmaller diviſions, and are finally diſperſed on the acini. The branches coming from different quarters anaſtomoſe freely in the gland.

Where the organ is ſurrounded by a membrane, as in the liver, kidney, teſtis, &c., the arteries penetrate on one ſide only, generally at a more or leſs deep notch, and in a ſingle conſiderable trunk, which, however, is ſometim[illegible] divided into a few ſmaller branches. The pa[illegible] the artery enters, is always the fartheſt removed from th[illegible] action of external bodies; a remark, which is commo[illegible] all important organs, as the lungs, inteſtines, ſpleen, &c. The convex ſurface of theſe, where the veſſels are the ſmalleſt, and where hæmorrhage would conſequently be attended with the leaſt danger, is always turned outw[illegible] When it has entered the gland, the main artery quickly [illegible]vides into various branches, which diverge and are ſubdi[illegible] as they approach the convexity. They have various branches in the body of the organ, as they proceed, and end by producing a large number of capillaries, covering the ſurface of the organ. Sometimes they come through, are viſible on the ſurface, and ramify between it and the inveſting membrane. The moſt favourable method of obſerving the diſtribution of the arterial ſyſtem in theſe organs is to inject them with hard injection, and to deſtroy the animal ſubſtance by means of immerſion in muriatic or nitric acids: a caſt of the vaſcular ſyſtem, even to its very minute diviſions, may be obtained in this way, and ſuch preparations, on account of their elegance, are contained in all cabinets. Ruyſch, who was remarkable for his dexterity in theſe proceſſes, found that the ſmall arteries were differently arranged in the different organs. In the kidney they are convoluted, ſo as to form, through the whole ſubſtance of the organ, ſmall granular bodies leſs than a pin's head, which are the acini already alluded to. The ſurface of the liver is covered, after a ſucceſsful injection, with innumerable capillaries arranged in a ſtellated form, and giving the appearance of little tufts of minute arteries, when the part is corroded, which have been compared to camel's hair pencils; and this arrangement has been termed the penicillous. A ſimilar diſpoſition is obſervable in the ſpleen.

Some have conceived that the large arterial trunks of glands communicate to the organs an interior motion very favourable to the execution of their functions. Theſe bodies are placed, for the moſt part, in the trunk, and therefore near to the heart; and their veſſels generally enter after a ſhort courſe, ſo that the impulſe has been conſidered, from this cauſe, to be more powerful. The ſpermatic artery is a remarkable exception to this obſervation, and the ſlowneſs of the ſeminal ſecretion has been explained from this cauſe. We own that we cannot diſcover any very convincing arguments in proof of theſe poſitions.

The veins accompany the arteries throughout, in their diſtribution to the glands; we have no diſtinction here of a ſuperficial and deep-ſeated ſet. The liver is the only example in which red blood enters on one ſide, and black goes out in the oppoſite direction.

Blood of the glands.—The quantity of blood contained habitually in theſe organs differs remarkably in the different parts of the ſyſtem. 1. The conglomerate glands contain very little. It imparts no colour to theſe organs, which are whitiſh in their appearance, and only require the water to be changed two or three times in maceration. 2. The mucous glands, proſtate, and teſticle contain a larger quantity. 3. The liver and kidney have ſuch a conſiderable portion, that they differ widely in this reſpect from the reſt of the glandular ſyſtem. They contain a large quantity even after death from hæmorrhage, or when the glands are ſuddenly removed from a living animal. Hence, when we macerate theſe organs, it is neceſſary to renew the water at leaſt twelve times before it ceaſes to be bloody: when we preſerve them in alcohol, long previous maceration is neceſſary, to prevent the ſpirit from becoming turbid by the blood. This large quantity of blood occaſions the glands now under conſideration to be heavier than the other parts of the ſyſtem; hence, too, ariſes their diſtinguiſhing red colour, which is not more eſſentially inherent in their tiſſue, than in [illegible]s ſurfaces or muſcles: in fact repeated waſhings will diſ[illegible]. The [illegible] tiſſue, as white is that of the muſcular fibre. The hue of the kidney ſeems to be leſs immediately influenced by the blood. It retains a degree of redneſs after frequent renewals of the macerating water; and the pulp produced by leaving it in water for ſome months, with frequent changes, ſtill has a red tint, although leſs deep than in the recent ſtate. Does the ſtate of the ſecretion influence the quantity of blood contained in glandular organs? Is there more blood ſent to the kidney, when the urinary fluid is ſeparated abundantly, than when it paſſes off ſlowly? or is there leſs returned by the veins in the former caſe?

Nerves.—Glands receive two kinds of nerves. 1. The lacrymal and ſalivary glands, the tonſils, &c. are ſupplied almoſt excluſively from the cerebral nerves. 2. The teſticles, proſtate, and liver, derive nearly an equal portion from the brain and the ganglia. 3. The kidney and moſt of the mucous glands, &c. are almoſt entirely ſupplied from the ganglia. Theſe remarks apply to thoſe nerves only, which are unconnected with the arteries; for each arterial trunk penetrating a gland, is ſurrounded by a nervous network belonging to the ſyſtem of the ganglia, and very manifeſt in the larger organs, as the liver and kidney, where the plexuſes come from the ſemilunar ganglion, in the ſalivary glands, where it is derived from the ſuperior cervical, in the teſtis from the lumbar, &c.

The nerves are ſmall compared to the ſize of the glands. We muſt not decide on this ſubject from thoſe which enter the parotid and ſubmaxillary; for the nerves merely traverſe thoſe organs, leaving a few branches behind them. But the liver obviouſly poſſeſſes as ſmall a ſupply as any organ in the economy, which receives nerves at all. Nerves enter the glands, like the veſſels; that is, they come in on all ſides where there is no ſurrounding membrane; and enter at the notch in other caſes. They divide and ſubdivide, as ſoon as they reach the gland, and are quickly loſt. There are never any ganglia in the interior of theſe organs.

We know but little of the exhaling and abſorbing veſſels in the ſubſtance of glands, where they are merely ſubſervient to the purpoſes of nutrition.

Properties of the Glandular Tiſſue.

1. *Properties derived from their Organization.*—Theſe are

very ſlightly marked in this ſyſtem, probably from its texture not partaking at all of the fibrous nature. In order that an organ ſhould be ſuſceptible of elongation and ſubſequent contraction, without injury, its component particles muſt poſſeſs a certain degree of coheſion; and this attribute particularly belongs to fibre. The glandular ſyſtem, too, is ſubject much leſs frequently to cauſes of diſtention and contraction, than thoſe which are made up of fibres. Where the liver contains a large quantity of blood after death, in conſequence of the venous ſyſtem being overloaded, its bulk remains the ſame: its ſubſtance is compreſſed by the veſſels. The enlargement of the teſticle in gonorrhæa, and of the parotid glands under certain circumſtances, and their ſpeedy ſubſequent reduction, prove that theſe organs poſſeſs a certain degree of extenſibility and contractility. Are the liver, kidney, and other internal glands ſubject to ſimilar acute enlargements? The phenomena now alluded to may take place in the cellular tiſſue of the glands, and therefore ſuppoſe a leſs degree of extenſibility in the proper ſubſtance of the gland than might at firſt have been ſuppoſed.

2. *Vital properties of the glands, and phyſiology of ſecretion.*—The remainder of the inveſtigation is much more difficult than what we have already gone through. The nature and properties of the fluids, and the ſtructure of the ſecreting organs, may be determined in a great meaſure by the evidence of our ſenſes: but when we endeavour to explain why each particular fluid is ſeparated by its reſpective organ, the determination of the queſtion implies a knowledge of the hidden ſtructure of the minute elements of our body, about which we muſt either be ſilent, or attempt conjectural explanation, at ſome riſk of expoſing ourſelves. The object then is, to ſhew, why, in the healthy ſtate of the body, ſaliva, and no other fluid, is conſtantly ſeparated from the blood in the parotid gland, bile in the liver, and urine in the kidney; and how it happens that the nature of the ſecretion never changes, ſo that urine ſhould be formed in a ſalivary gland, ſaliva in the kidney, bile in the mammary glands, &c. The difficulty of the undertaking is increaſed, and the proſpect of arriving at a ſatisfactory concluſion diminiſhed, by this circumſtance; that in the different claſſes of fluids, each is not conſtantly ſeparated in an organ of a particular ſtructure. If that were the caſe, it would only be neceſſary to determine the relation which the ſtructure of the gland bears to the nature of the ſecreted fluid: but the very contrary is the caſe. Fluids of each kind are produced by every variety of glandular apparatus: thus water is formed by the arteries of the ſkin, without any glandular arrangement, by conglomerate glands, in the inſtance of the ſalivary apparatus, and by a glandular viſcus in the caſe of the kidney: mucus is ſecreted by membranous ſurfaces, and by different kinds of glands; and laſtly, oily matters are poured from the arteries of the cellular membrane, from various ſebaceous glands, from the veſſels of the ſkin, from the liver, &c. Again, there are inſtances in the body, of organs, which we ſhould, *à priori*, have pronounced, without heſitation, to be glandular, and which yet perform no ſecretion. Such are the ſpleen and thyroid gland, to which we may perhaps add the thymus and renal capſules. The ſpleen is a remarkable inſtance of the arrangement of the minute arteries, called the penicillous, which is ſeen alſo in the liver, and conſidered to have much connection with the peculiar functions of the ſecretory organs. In this place, too, we ſhould mention the curious facts, concerning the formation of certain fluids, under particular circumſtances, by other glands than thoſe which ordinarily produce them.

Haller has collected, in his great work, a vaſt number of facts of this deſcription; of which, if we ſhould reject all that may ſeem inſufficiently authenticated, there will remain quite enough to prove the point deciſively. To the chapter in which theſe details are contained, he prefixes this ſentence: "fere quilibet humor per quodcunque colum ſeparari poteſt;" and the caſes which he cites, fully juſtify his concluding paragraph: "Quando hæc exempla repetemus, conſtabit, non ejuſdem unice claſſis diverſos humores ſua inter ſe cola commutare, ſed etiam per muci organa aquam, per muci, aquæ et adipis cola lympham et ſanguinem, per aquæ, muci et lymphæ vias adipem, bilem ſanguinemque ſecerni, atque adeo omnino, nullum in animato corpore ſeparatorium organum eſſe, quod non omnium claſſium humores ſuis cum dotibus ſecernere queat." Element. Phyſiolog lib. 7. cap. 1. §. 9. When theſe circumſtances are conſidered, it will very probably be ſuſpected that the cauſes of the differences in the ſecreted fluids cannot be traced in the obvious ſtructure of the glands; but that the reaſon why a peculiar fluid and no other is ſeparated from each gland, in the healthy ſtate of the body, lies much deeper, and flows from ſome conditions of the organs, which are inacceſſible to our ſenſes. We ſhall endeavour to illuſtrate the ſubject as far as well authenticated facts will aſſiſt us, and ſhall mention the opinions which have been moſt prevalent on the ſubject. It will be an eaſier taſk to ſhew how unſatisfactory moſt of theſe are, than to ſubſtitute any thing more rational in their place. We proceed to point out the vital properties of the glands.

No part of the ſyſtem poſſeſſes animal contractility, or the power of voluntary motion. Different glands ſeem to be differently circumſtanced with reſpect to the correſponding ſpecies of ſenſibility. The peculiar and oppreſſive ſenſation occaſioned by compreſſion of the teſticle, is well known. Conſiderable and continued preſſure on the parotid gland has produced great ſuffering; but large nerves paſs through this organ. The liver may be injured in a living animal, without cauſing any of the uſual ſigns of pain; and Haller makes the ſame obſervation concerning the glandular ſyſtem in general, but his ſtatement is not perfectly explicit: "Univerſæ glandulæ experienti minime irritabiles videntur, neque vehementer aut morbos ſentiunt, aut illatas a profectore injurias." Elem. Phyſiol. t. 2. p. 377. Stones in the kidnies often cauſe very ſevere pain. From theſe apparently contradictory circumſtances, we can only conclude that animal ſenſibility, which is variouſly modified, may exiſt in organs, where certain agents do not excite it at all, while others develope it very readily. In fact, various morbid alterations render this property very manifeſt in the glands. The pain of inflammation bears, indeed, a peculiar character in the glandular ſyſtem; it is generally obtuſe and heavy.

Properties of the organic life.—Senſible organic contractility does not exiſt in the glandular ſyſtem: but the two other organic powers are exhibited in their higheſt ſtate of developement, and are almoſt conſtantly in operation, being concerned in ſecretion, excretion, and nutrition. Organic ſenſibility enables the gland to diſtinguiſh in the maſs of blood thoſe materials which are ſuitable to its ſecretion; and by its inſenſible contractility, it has the power of rejecting whatever is heterogeneous. The blood contains the materials of all the ſecretions, of the nutrition of all organs, and of all the exhalations. From this common reſervoir each gland draws what is requiſite for its ſecretion, each organ for its nutrition, and every ſerous ſurface for its exhalation. The peculiar mode of organic ſenſibility enables each living part to diſtinguiſh what its functions require. The whole buſineſs of glandular action reſts on the two powers juſt mentioned; and as this action is nearly conſtant, they are almoſt inceſſantly exerted.

It is evident that all glandular affections muſt imply a diſorder in the powers above-mentioned; ſince diſeaſes of an organ are particularly determined by alterations of the leading properties; of thoſe which conſtitute the peculiar life of the part. Obſervation proves this: we ſee theſe properties, when augmented or diminiſhed, producing on one ſide increaſed ſecretion, as in diabetes, mercurial ſalivation, cholera morbus, &c.; on the other, a decreaſe or even ſuſpenſion of the function, as in acute diſeaſes, where all the ſecretory tubes ſeem, as it were, cloſed for a time; for inſtance, in ſuppreſſion of urine, dry ſtate of the mouth, &c. On other occaſions the nature of the glandular ſenſibility is changed, and it harmonizes with ſubſtances which are not admitted in the healthy ſtate: hence the innumerable varieties of the ſecreted fluids under circumſtances of diſeaſe. The cyſtic bile in the dead body preſents numerous varieties of taſte, ſmell, colour, and conſiſtence. The numerous alterations of the urine are well known. The ſaliva is leſs liable to change; but how different is it in many diſeaſes from its ordinary condition. Nothing can leſs reſemble urine or bile than the fluids often diſcharged from the bladder and liver: whence then ariſe theſe differences? from the variations in the organic ſenſibility bringing the part into a relation with thoſe ſubſtances, which were foreign to it in the natural ſtate. Thus the ſame gland, without any change in its ſtructure, but merely by altered modifications of its vital powers, may be the ſource of infinitely varying fluids. Might not this be carried ſo far as to allow that the kidney, by aſſuming a ſenſibility analogous to that of the liver, may actually form bile? why ſhould it not ſecrete bile, ſince it does ſeparate other fluids ſo widely different from the urine?

In the healthy ſtate, the mode of ſenſibility in each gland is nearly uniform; and the ſecreted fluid is conſequently nearly the ſame in its compoſition and properties. But the mode is changed by numerous cauſes in diſeaſe. An hyſterical attack comes on; ſuddenly the kidney refuſes to tranſmit the principles which colour the urine, and that fluid is conſequently diſcharged limpid; as the paroxyſm ſubſides, the natural type of the ſenſibility is reſtored, and the urine has its accuſtomed characters. In an epileptic fit, a thick frothy ſaliva is diſcharged from the mouth in abundance; as the attack goes off, the ſalivary ſecretion returns to its natural ſtate.

The various changes in the organic ſenſibility, and the inſenſible contractility of the glands, do not affect the function of ſecretion only; but when they laſt for ſome time, they influence nutrition alſo. From the diſturbances of this proceſs ariſe thoſe various organic affections, of which the glandular ſyſtem offers the moſt abundant harveſt to the pathological anatomiſt. We cannot avoid noticing, in diſſecting rooms, the numerous diſeaſes obſerved in this part of the body compared to others. The glands, the ſkin, the mucous, ſerous, and cellular ſyſtem, hold the firſt rank in this reſpect; and in all theſe the two properties above-mentioned exiſt in the higheſt degree, and are called into action, not merely by nutrition, but alſo by various other functions, which reſide in the capillary ſyſtem, as exhalation, abſorption, and ſecretion.

The preceding account of the phyſiology of ſecretion, chiefly derived from the "Anatomie Generale" of Bichat, ſeems to amount to little more than this, that each ſecretory organ produces its peculiar product, in conſequence of its poſſeſſing peculiar vital properties, which, when variouſly modified under particular circumſtances, enable the organ to ſeparate very different fluids from the blood. And this we believe to be a pretty correct ſtatement of the extent of our knowledge of this ſubject. But anatomiſts and phyſiologiſts, not ſatisfied with this ſimple fact, have endeavoured to develope the exact mechaniſm of the proceſs, and it will be neceſſary for us to recount ſome of their opinions. In all obſervations on this ſubject, it will be well for us to remember that ſecretion is not confined to the animal kingdom, but prevails alſo in the vegetable world. We frequently obſerve the ſap giving origin to peculiar and different juices in the various parts of the ſame plant, and reaſoners from analogy have gone ſo far as to admit the exiſtence of a glandular ſyſtem in vegetables. We ſhall be induced, by this circumſtance, not to lay too much ſtreſs on the peculiar ſtructure of the ſecretory organs in the more complicated animals, as eſſential to the buſineſs of ſecretion. Many of the facts already noticed, concerning the ſeparation of perfectly ſimilar, or at leaſt very cloſely reſembling fluids, by means of totally diſſimilar organs, will tend to the ſame deduction. And this mode of argument may be ſtill further ſupported by various examples in comparative anatomy; where we find fluids of the ſame claſs ſecreted in animals of different orders, in organs of very different external appearance. The kidnies of birds are really conglomerate in their ſtructure; and a fluid, exactly reſembling the pancreatic of warm-blooded animals is formed by the tubular pyloric appendages, variouſly conſtituted in different genera of fiſhes.

Of the different explanations, by which phyſiologiſts have ſucceſſively attempted to elucidate the function of ſecretion, moſt are completely hypothetical and improbable. In moſt inſtances it has been aſſumed that the various animal fluids are all contained in the blood; and ſecretion, according to this opinion, conſiſts ſimply in their ſeparation by means of the glands. Differences in the diameter, length, and folds of the veſſels, and ſuppoſed varieties in the holes with which the glandular ſyſtem is ſuppoſed to be perforated, have been employed as the means of rendering the mechaniſm of ſecretion intelligible; hence the expreſſions of ſieves, filters, and ſtrainers, ſo frequently employed in phyſiology. We are diſpenſed from the neceſſity of commenting on the glaring abſurdity of comparing a gland to a ſieve or filter, and of deciding which of theſe mechanical explanations is the moſt exquiſitely fooliſh, by the completely gratuitous nature of the fundamental propoſition. The modern analyſes of the blood have no longer even the ſhadow of an excuſe for regarding this fluid as a mixture of all the animal liquors, and for ſuppoſing that it is formed of ſaliva, bile, gaſtric juice, urine, &c. ſince we can diſcover no trace of ſuch fluids in it. Although all the elements neceſſary to form theſe products, as well indeed as thoſe of the ſolids, are in fact found in the blood, they exiſt in it in a different ſtate of combination. The blood is manifeſtly an homogeneous liquor, capable of forming all animal matters from the moſt tranſparent and pure water, as the cutaneous exhalation, to the firm fabric of the bony ſyſtem; from it are formed ſaliva, bile, and urine; and it ſerves alſo for the nutrition of muſcles, membranes, and nerves; but none of theſe modifications of animal ſubſtance are contained in it perfectly formed.

Their precipitation, ſays Fourcroy, in the tiſſues to which they belong, cannot be regarded as a ſimple ſeparation; ſince it is accompanied by a modification in the properties, nature, and compoſition of each. Thus the cerebral pulp is not exactly the ſame albuminous matter as that in the ſerum of the blood; the gelatine is not iſolated in this fluid, as in the membranous tiſſue; the muſcular fibrine is not completely identical in its character with that which exiſts in the blood; and the phoſphate of lime is not aſſociated in the latter to the gelatinous ſubſtance, which unites its particles in the bony ſyſtem. Hence ſecretion always implies ſome change or modification in the matter which reſults from its exerciſe. Connoiſſ. Chim. ſect. 8. ord. 4. art. 5.

Another notion, as deſtitute of all ſolid foundation as the former, is, that the blood undergoes certain changes as it arrives at the glands; that it aſſumes a peculiar compoſition before it penetrates the organ. It has been aſſerted that the blood-veſſels are ſo arranged as to produce particular modifications in the contained fluid, and that this is a diſpoſition preparatory to the final proceſs. The hepatic ſecretion has been conſidered to afford the cleareſt example of ſuch previous changes. The ſtructure and number of the veſſels which ſurround and enter the organ, the proportion of thoſe which carry blood or white fluids, the different temperatures ſuppoſed to depend on theſe proportions, in a word, all thoſe points of organization which can poſſibly influence the nature of the blood, are ſaid to be ſufficiently diverſified in order to produce in the chemical properties of the fluids a diſpoſition favourable to the formation of ſaliva in the neighbourhood of the ſalivary glands, of urine in that of the kidney, &c. This diſpoſition, depending on the vaſcular apparatus, has been repreſented to conſiſt particularly in a retardation, acceleration, cooling or warming of the blood, or in the loſs, by abſorption, of ſome of its principles. But what ſenſible cauſe can produce theſe effects? Does not the blood flow through the trunks which are going to the glands juſt as in other veſſels? In ſhort, what is the change? The ſuppoſition in queſtion is a complete aſſumption; not ſupported by a ſingle fact, and contrary to obſervation as far as our knowledge hitherto extends. For we can detect no difference in the blood drawn from the carotid, ſpermatic, hepatic or renal arteries. We have been ſurpriſed to find this opinion adopted and ſupported by Fourcroy; but the whole of his remarks on the ſubject in the "Syſteme des Connoiſſances Chimiques," ſect. 8. ord. 4. art. 5. do not contain a ſingle proof, and afford an example of vague and completely illogical ſtatements. We do not mean to deny that there may be particular conditions of the whole maſs of blood favourable to certain ſecretions. Thus, after drinking copiouſly of watery fluids, we find a much larger portion of urine ſecreted; and the cutaneous exhalation is often augmented from the ſame cauſe.

In our endeavours to diſcover the mechaniſm of ſecretion, it will be beſt for us to ſelect the moſt ſimple mode of this function. Now the exhalation from ſerous membranes, and the mucous fluid covering the ſurface of many cavities in the body, are examples of this kind. We can diſcover nothing in theſe organs but vaſcular ramifications united by cellular ſubſtance. Injected fluids in the dead body follow the ſame route which the ſecreted liquors follow in the living ſtate. And the ſame obſervation may be applied alſo to the caſe of ſecretions in ſome of the more complex inſtances. "Water," ſays Haller, "tinged with colouring matter, iſinglaſs, or oil of turpentine, thrown into the arteries of a young ſubject, and occaſionally even ſuet, in the experiments of Ruyſch and Albinus, have exuded in numerous ſmall drops from the ſkin, after the removal of the cuticle in warm water, ſo as to imitate very cloſely the proceedings of nature. I have alſo repeatedly ſeen water, coloured with blue, and injected into the lungs through the inferior cava, run out with much froth from the trachea. In the kidney, water, air, or ſuet will paſs through excretory tubes continuous with the arteries into the infundibula and pelvis. Oil of turpentine and quickſilver have paſſed into the chamber of the aqueous humour from the arteries: in the ſame way injected water imitates the courſe of the tears, and exudes abundantly from the whole internal ſurface of the eye-lids." Elem. Phyſiol. t. 2. p. 374. Phyſiologiſts have indulged in conſiderable diſputes concerning this kind of ſecretions. "Some," ſays Blumenbach, "aſſert that all ſeparation of fluids from the maſs of blood is accompliſhed merely by pores in the blood-veſſels, and thoſe, as they ſay, of an inorganic nature; while others deny altogether the exiſtence of ſecretory pores. I ſuſpect that this difference of opinion muſt be reſolved into a verbal diſpute. On the one hand, I muſt confeſs, unequivocally, that I know not what notion to form of inorganic pores in an organized body, ſince all the openings in ſuch bodies muſt belong to their organic nature, and be regulated by their vital properties. On the other ſide I do not conceive that the orifices or pores in the coats of the veſſels, the exiſtence of which cannot be doubted, differ eſſentially, in regard to their functions, from the cylindrical ducts, in which ſecretion is performed in the conglomerate glands, and in the glandular viſcera: ſince it is probable that the ſeparation of fluids depends more on the vital properties than on the forms of the ſecretory organs." Inſtitut. Phyſiolog. ſect. 32. § 469, note *b*.

However ſimple the proceſs of ſecretion may be deemed in the caſe juſt ſpecified, and however cloſely the proceedings of nature may be imitated by the experiments with injections, we ſhall ſtill find ourſelves entirely ignorant of the eſſential circumſtances of the proceſs; *i. e.* we cannot explain the formation of the new product from the blood, and the formation of ſuch totally different new combinations in organs where no difference of ſtructure can be detected.

Thoſe, who wiſh to ſee the various attempts at explaining the mechaniſm of ſecretion, may find ample gratification in the third ſection of the ſeventh book of Haller's great work: where he gives his uſual detail of all that has been written on the ſubject. The reader will be very willing to ſpare us the taſk of recounting all theſe dreams, and the ſtill more diſguſting toil of refuting them. We ſhall merely mention one opinion, on which phyſiologiſts lay ſome ſtreſs even in the preſent day. This refers the difference of the ſecreted matters to the peculiar arrangements of the minute arteries of the glands. Ruyſch, who excelled in the art of making anatomical preparations, was led to remark, in his employment of injections, that the ultimate arterial ramifications differ in the different ſecretory organs, and indeed that there are characteriſtic differences in this reſpect in all the ſtructures of the body. This explanation may poſſibly be true, and we cannot perhaps completely overthrow it: but this is all that we can ſay in its behalf. We muſt obſerve, in the firſt place, that a correct account of the facts, and an exact deſcription of the different vaſcular networks, is yet a deſideratum; for the queſtion concerns the very ſmalleſt capillaries, from which the tubes conveying the new product commence. Now the larger ramifications, ſuch, for inſtance, as will admit ſeveral globules, do not differ ſufficiently from each other to account for the diverſity of the fluids produced in the various organs. Indeed ſimilar veſſels often produce the moſt oppoſite products. The ſtructure of the cortex cerebri, of the ſpleen, and of the placenta, is very much alike with the moſt diſſimilar reſults. The veins, too, are arranged like the arteries, as we ſhould conclude, certainly not for the purpoſes of ſecretion. Very different arrangements of blood-veſſels may be ſeen in various membranes which produce the ſame kind of exhalation.

Recourſe has been had to the ſcience of chemiſtry, in order to explain the function of ſecretion, but no aſſiſtance has been hitherto derived from this ſource in unfolding the myſtery. That the changes, by which the new products conſtituting the animal fluids are produced from the blood are purely chemical, cannot be doubted, but we are equally in the dark as to the circumſtances which determine or modify theſe alterations. We cannot doubt indeed that the whole eſſentially depends on a vital power of which chemiſtry can neither detect the nature, nor appretiate the force. If, however, we cannot be very ſanguine in expecting from this ſcience a developement of the immediate agent by which ſecretion is effected, much light may, probably, be thrown on ſome parts of the ſubject by accurate chemical inveſtigations. We may apply generally the obſervation of Dr. Thomſon concerning the kidnies: "the changes operated on the blood in the kidnies are at preſent altogether unknown; but they muſt be important. Provided the method of analyſing animal ſubſtances was ſo far perfected as to admit of accurate concluſions, conſiderable light might be thrown upon this ſubject, by analyſing with care a portion of blood from the emulgent artery and vein ſeparately, and aſcertaining preciſely in what particulars they differ from each other." Syſtem of Chemiſtry, vol. 5. p. 749. Fourcroy, too, in conſidering how far ſecretion admits of explanation on chemical principles, ſpeaks rather of what may be done than of what has been effected in this way. "Hitherto chemiſtry can only furniſh ſome general ſtatements on this ſubject; and, if we look to this ſcience for an explanation of the cauſes and products of the ſecretions, and for a demonſtration of what paſſes in every kind of ſecretion in particular, we muſt wait till the experiments are much more numerous, the inveſtigations more exact, and the animal analyſes conſiderably multiplied. We muſt determine the temperature, conſiſtence, and nature of the cerebral blood, of that in the vena portarum, and in the renal arteries, before we can underſtand the mechaniſm of the ſecretions performed in the brain, liver, and kidnies." Syſt. des Conn. Chimi. v. 10, p. 385.

We ſhould always bear in mind, in our attempts at chemical explanations of the animal functions, that the effects of the vital power are more particularly obſervable in counteracting and preventing the exertion of thoſe affinities, by which dead animal matters are regulated; and conſequently, that if ſecretion be an example of chemical affinity, it is ſo modified by the vital powers, that we can have very little hope of imitating it by experiments out of the body.

In what manner, and to what extent, are the ſecretions influenced by the nerves? The fact that glands have a ſupply of nerves, leads us to expect *à priori* that the effects of their operation will be very obvious; but the laws, which regulate this matter, are hitherto by no means clearly aſcertained, and even the kind of influence is very obſcure. There is a want of direct evidence, from experiment, on this ſubject. "I divided," ſays Bichat, "the nerves of the teſticle in a dog: the gland inflamed and ſuppurated; but the latter occurrence ſhews that nervous influence is not neceſſary for ſecretion, ſince ſuppuration is accompliſhed in a manner analogous to that of the latter functions. Phyſicians know very well that paralyſed limbs may inflame and ſuppurate. Erection and expulſion of the ſemen may occur, when the lower half of the body is paralyſed, and when the nerves of the proſtate at leaſt muſt have entirely loſt their influence. An example was related to me of a ſoldier, who contracted a gonorrhæa in this ſtate. In complete paralyſis of the bladder, mucus is ſtill ſecreted in ſufficient abundance. The noſtril of the affected ſide is as moiſt as uſual in hemiplegia; and an equal quantity of cerumen is produced in the meatus auditorius of the ſame ſide. The glands of the uvula do not ceaſe to act where that organ is paralyſed. After cutting the nerve of the eighth pair on one ſide in a dog, the air-veſſels are equally full of mucus on that ſide. In the convulſed ſtate of ſuch parts as poſſeſs glands, where the nerves of theſe organs muſt conſequently be unuſually excited, there is no augmentation of the ſecretion." Anatomie Generale, tom. 4. p. 604. We may obſerve further, that when the influence of the brain on the organs of the animal life is completely ſuſpended in apoplexy or compreſſion, where ſenſation and voluntary motion are loſt, the ſecretions continue undiſturbed. On the other ſide we may adduce numerous phenomena, which can be accounted for only through the agency of the nervous ſyſtem. Under this head we may mention the flow of ſaliva on the ſight of food, the increaſed lacrymal ſecretion produced by various affections of the mind, the ſuppreſſed diſcharge from the ſkin from the ſame cauſe. The urinary ſecretion is often ſuddenly affected in hypochondriacal perſons; diſtreſſing news will occaſion it to be ſecreted in great abundance, and of a very pale colour; and many remarkable inſtances have been recorded, where the biliary ſecretion has been decidedly and ſuddenly affected by mental emotions. It has been aſſerted, but we know not on what authority, that a cow, after being milked by the ſame individual for a long time, will give much leſs milk, if the operation be performed by a ſtranger. Theſe and other analogous facts have led many phyſiologiſts to admit of a nervous influence in the affair of ſecretion; the mode and degree of this action have been variouſly eſtimated. De Berger conceives that the tone of the ſecretory organs was kept up by the nervous fluid; De Natura Humana, p. 122. Queſnay referred the differences of the ſecreted fluids to various degrees of ſenſibility in the ſecretory veſſels; Eſſais ſur l'Econ. Anim. t. 3. p. 437. De Bordeu aſcribed great influence to the nerves on the ſecreting arteries; Recherches ſur les Glandes, p. 352. Stahl and his followers, who aſcribed the power of guiding the vital motions to the ſoul (anima), conceived that it governed the buſineſs of ſecretion alſo; and A. F. Hoffman aſcribes the difference of the fluids entirely to the anima, which regulates the ſecretory orifices by ſphincters and valves, now cloſing them to prevent the entrance of particles heterogeneous to the fluid intended to be formed, and now opening them for the entrance of the ſuitable molecules; Nov. Hypotheſ. Phyſiolog. p. 13. After recounting theſe opinions, Haller obſerves that they aſcribe too great an influence to the nerves, and reminds his reader that ſecretions of various kinds are performed in plants, without the aſſiſtance of nerves; and that balſams, reſins, gums, and coloured milky fluid is formed from the common liquor taken in by the roots of the vegetable. On this ſubject we may obſerve, with Bichat, that the expreſſion *nervous influence* has generally been uſed by phyſiologiſts in a very indefinite manner. When the irritation, diviſion, or paralyſis of a nerve ſupplying a voluntary organ interrupts, or entirely deſtroys its functions, we can obſerve and appretiate the influence of the nerves on ſuch organs; but, with what propriety can we employ the ſame term to deſignate the power, which the nerves may poſſibly have over the ſecretory organs, when their diviſion or paralyſis does not at all diſturb the functions of the part?

The ſecretions may be affected by the direct action of external irritants, although mechanical or chemical irritation in the living body produces no ſenſible motion or contraction of the organ. Thus, any acid matter will augment the flow of mucus from thoſe ſurfaces which ſecrete it; and the ſlighteſt irritation of the conjunctiva increaſes the ſecretion of the lacrymal gland. The preſence of food in the mouth excites the ſalivary organs; and the act of ſuckling or milking produces a ſecretion of milk, &c. &c.

The ſame powers by which ſecretion is effected accompliſh the paſſage of the fluid, when produced, through its excretory tubes; it is the inſenſible organic contractility by which this is effected. Experiments on the ducts of glands in living animals, ſhew that they are not affected by chemical or mechanical irritation, and hence many have concluded that they poſſeſs no power of contraction; but the phenomena render it neceſſary to allow them ſuch a property, which may exiſt in parts, although the trials juſt mentioned ſhould not render it obvious. External preſſures and extraneous influence of other kinds have been reſorted to, in order to account for the expulſion of the fluids contained in excretory tubes, on the idea that theſe canals poſſeſſed no contractile powers in themſelves. Such explanations are quite gratuitous aſſumptions in all caſes; and in many inſtances are totally and manifeſtly inadequate, becauſe the organ is expoſed to no agency of the kind.

The ſecreted fluid in ſome inſtances is not conveyed immediately to the point of its ultimate deſtination; but is either retained in the excretory tubes, or kept in particular reſervoirs; and it has been ſuppoſed that various changes take place in its nature and properties under theſe circumſtances. "Frequentiſſime," ſays Haller, "hoc mechaniſmo natura utitur, ut humorem ſecretum retineat, perficiat, inſpiſſet, ad deſtinatos uſus contemperet, legitima occaſione effundat." Elem. Phyſiol. t. ii. p. 445. The urinary and gall-bladders are the moſt remarkable inſtances of this deſcription: we may mention alſo the veſiculæ ſeminales, and the mucous ducts of the urethra and female organs of generation. That the ſecreted fluids in theſe, and in ſeveral other inſtances, are conſiderably altered after the time of their firſt production, cannot admit of a doubt, as mere inſpection is ſufficient to prove it; the particular changes produced in each caſe will be conſidered in the account of the various organs. The opinions entertained concerning the general effects of theſe reſervoirs, are, that the fluids are inſpiſſated by an abſorption of theſe aqueous parts, that they are depurated, or rendered more perfect, and variouſly mixed together: it is added, that their retention in the heat of the living animal body in many inſtances renders them acrimonious, and that this change, in many caſes, as in the bile and ſemen, promotes the views of nature. Theſe notions are not very conſiſtent with each other, nor very clear in themſelves: the latter ſuppoſition, concerning the acrimonious tendency of the fluids, is founded on the obſervation of the changes occurring out of the body, and is not at all warranted by obſervation of the living ſubject, in which chemical alterations are reſiſted by the vital powers.

We have every reaſon to ſuppoſe that much of the ſecreted fluids is taken up and carried into the circulation by the abſorbents; but our knowledge does not enable us to determine the exact extent or nature of the modification, which the function of ſecretion undergoes from this cauſe. The experiments of Bichat prove that the various animal products, even thoſe which we ſhould at firſt have regarded as the moſt noxious, may be introduced into the venous ſyſtem without eſſential injury to the animal; ſo that the blood may be deemed a common fluid, receiving and retaining various principles, which may vary according to circumſtances. "I injected," ſays Bichat, "into the jugular veins of ſeveral dogs, cyſtic bile taken from other dogs opened at the ſame time. During the firſt days they appeared weary, did not eat, were very thirſty, had a dull look about the eyes, and were conſtantly lying down; in a little time, however, they gradually recovered their original vigour. I have ſince employed human bile in ſimilar experiments: the reſults were the ſame, except that hiccough and vomiting took place ſoon after the experiment. In one inſtance the animal died three hours after the injection; here I had uſed bile of an extremely deep black colour, like thick ink, ſuch as is occaſionally ſeen in the gall-bladder, and ſeems to form an eſſential part of the black vomitings obſerved in certain caſes. When ſimilar trials were made with ſaliva, the conſequent languor was leſs ſenſible. I then tried mucus of the noſe ſuſpended in water. Laſtly urine itſelf, not of the aqueous kind, but that of coction, was employed; the conſequent illneſs was more ſevere, but one animal only died, and I ſuſpect that this fatal event happened from the unguarded introduction of a little air at the time of the experiment." Anatomie Generale, t. 4. p. 587. He obſerves afterwards that the injection of any animal fluids into the carotid artery is immediately fatal, from the effects produced on the brain: but they may be thrown with impunity into other parts of the arterial ſyſtem, as, for inſtance, into the crural artery.

Sympathies of the glandular ſyſtem.—Theſe may be divided into the paſſive and active. The glandular tiſſue is very readily influenced by various excitements, either in the natural ſtate, or in diſeaſes, which conſtitute its paſſive ſympathies. The caſes in which the excitation of other organs augments glandular action, are particularly obſervable in the mucous ſyſtem. Moſt of the excretory ducts open on ſurfaces of this nature; and examples of the obſervation occur in the flow of ſaliva determined by the preſence of food in the mouth; in that of urine produced by catheters retained in the bladder; in the ſeminal excretion produced by irritation of the glans; the flow of tears from irritation of the conjunctiva or pituitary membrane; and in that of bile during the paſſage of the food into the ſmall inteſtine.

The glandular ſyſtem frequently exhibits paſſive ſympathies in diſeaſe; the organic properties are brought into action under theſe circumſtances, the animal ſenſibility being very ſeldom developed ſo as to produce pain. The innumerable varieties in the quantity or quality of fluids ſeparated by the glands under circumſtances of diſeaſe ariſe principally from ſympathetic influence. Thus the ſalivary apparatus moiſtens the mouth, or leaves it dry; fills it with a viſcid or a thin fluid, &c. The mucous organs cover the tongue with matters of moſt varying conſiſtence, thickneſs, and colour; and this occurs from ſympathy with various ſtates of the ſtomach. The liver, kidney, and pancreas are influenced in very numerous ways; wherever any organ in the animal economy is affected, theſe are deranged; their ſecretion is increaſed, diminiſhed, or altered, and frequently even inflammation and ſuppuration ſupervene. The affections of the liver from injuries of the head are well known; and the lacrymal ſecretion is variouſly modified in inflammatory and malignant fevers, ſo as to produce various appearances of the eyes. Weeping in various mental affections is another example of ſympathetic influence. The teſticles and proſtate exhibit fewer inſtances of ſuch ſympathies, probably becauſe their functions are ſo much more iſolated. The relations which connect the breaſts and uterus are remarkable, and frequently obſerved. In the ſequel of conſiderable acute diſeaſes, particularly fevers, the action of the glands is often conſiderably affected, and copious evacuations, called critical, the nature of which is not yet clearly explained, take place.

The active ſympathies are leſs frequent than thoſe of the preceding claſs; but diſeaſes exhibit inſtances of them. Inflammations of the liver, kidney, ſalivary ſyſtem, &c. ſhew various phenomena produced ſympathetically in other ſyſtems.

Bichat, in his Anatomie Generale, gives the following view of the characters which diſtinguiſh the vital properties of the glandular ſyſtem.

1ſt. *Peculiar vitality (vita propria) of each gland.*—The vitality of the glands, reſulting from the preceding powers conſidered in a ſtate of action, is not uniform in the whole ſyſtem; becauſe the ſtructure varies in every inſtance, and each tiſſue poſſeſſes a peculiar modification of vitality. Hence reſult many phenomena noticed by Bordeu. 1. There are certain matters on which alone each gland can act in the natural ſtate. Thus the ſalivary apparatus does not form bile, the liver does not ſeparate urine, &c.; and on this principle the difference of the ſecretions is founded. In the ſame way cantharides act particularly on the urinary organs; mercury on the ſalivary glands, &c. 2. Each gland has its particular mode of ſympathy. Thus the liver acts eſpecially on the brain, the kidney influences the ſtomach, the uterus and breaſts affect each other, &c. 3. Each glandular inflammation has a peculiar character: that of the kidney is different from that of the liver or teſticle; the inflamed proſtate has very different ſymptoms from the teſtis in ſuch a condition. 4. Every gland has peculiar diſeaſes, or ſome at leaſt to which it is more expoſed than others. Hydatids, which are very common in the liver, are never ſeen in the ſalivary glands or teſticle. Sarcocele is extremely common, while nothing is more unfrequent than an enlarged parotid. The liver alone exhibits that peculiar alteration, which conſtitutes the fatty ſtate; and is the moſt frequent ſeat of ſteatomatous tumours. Phyſicians, who have not been converſant with the inſpection of morbid caſes, uſe the vague and inſignificant terms of obſtruction and induration for every kind of glandular enlargement. The increaſe of ſize is the only common character of ſuch affections, while the nature of the tumour is entirely different. 5. Every gland preſents ſome peculiar modifications in what are called the critical evacuations, occaſionally conſequent on acute diſeaſes. 6. The different vitality of the glands occaſions them to re-act at very different intervals, in conſequence of direct irritation, or ſympathetic excitation. The lacrymal gland, for example, pours out ſuddenly an abundant ſecretion, when irritated; while the kidnies or pancreas can be excited only very ſlowly.

2d *Character. Inactive ſtate of the vital powers.*—The glands are ſubject to habitual alternations of increaſed and diminiſhed action. The animal functions are eſpecially influenced by ſleep, which completely ſuſpends them. The action of the glands is only partially diminiſhed at certain times, except in diſeaſe, when it is ſometimes completely ſuſpended. Bichat compares the ſleep of the animal life to the intervals of intermittent fevers, where the apyrexia is complete: and the ſleep of the glands to thoſe of remittent fevers, where the ſymptoms are merely diminiſhed in degree. Saliva flows into the mouth abundantly during maſtication; it merely moiſtens the cavity at other times. The pancreas and liver pour out their ſecretions profuſely, while the food is in the duodenum: they act much leſs intenſely during the ſtate of abſtinence. The kidney is particularly exerted ſome little time after a meal. The intermiſſions in the action of the breaſts are almoſt as complete as thoſe of the organs of animal life. Every mucous gland has its particular period of ſecretion: it is, when the ſurface, on which the duct opens, is in contact with any ſubſtance either retained in the cavity, or paſſing through it. We muſt, therefore, form this notion of the office of the glands; that they conſtantly ſeparate a fluid from the blood, but that they are more active at certain periods, and conſequently furniſh a more abundant ſupply.

This remittence of the glandular action, ſays Bichat, depends on a cauſe analogous to that of ſleep, which ariſes, in the animal life, from the fatigue experienced by the organs of ſenſation and locomotion, after a continuance of action. The laſſitude, of which the glands are ſuſceptible, is not generally marked by any painful feeling; yet there is in the breaſt, after long ſuckling, a kind of dragging ſenſation, and actual pain is felt in the teſtis after emiſſion has been repeated two or three times.

3d *Character.*—The vitality of the glands is never encreaſed at the ſame time in the whole ſyſtem. When one is in action, the others are in a ſtate of remiſſion. We might conceive, ſays Bichat, that there is only a determinate quantity of vital powers for the whole, and that one cannot be exerted unuſually without a correſponding diminution in the reſt. The digeſtive apparatus is accommodated to this law. At firſt the ſalivary ſyſtem produces an abundant ſecretion; then the ſtomach comes into action; thirdly, when the chyme enters the duodenum, the liver and pancreas are principally exerted; at the fourth period, the mucous glands of the large inteſtine act; and laſtly, the kidney exerciſes its peculiar office to evacuate the reſidue of the fluids. All the glands cannot act at once; as, in the external movements, certain muſcles are always in a condition of repoſe, while others are contracted. The moſt improper time for coition is during digeſtion, becauſe the mucous, pancreatic, hepatic ſecretions, &c. muſt then be performed at the ſame time with that of the teſticle. In diſeaſes, the ſecretion of one gland is encreaſed at the expence of others. This character of the glandular ſyſtem is only an example of the general character belonging to all the vital powers, by which, when increaſed at one point, they are proportionally diminiſhed in ſome other ſituation. Hence large abſceſſes, conſiderable tumours, and dropſies are always attended with debility of the glandular action. On the ſame principle is founded the uſe of bliſters, ſetons, moxa, cauteries, &c. which do not act, as old phyſicians ſuppoſed, by evacuating any morbid matters, but by putting an end to the irritation in the diſeaſed part, by means of that which they determine in ſome other organ.

4th *Character.*—Influence of climate and the ſeaſons on the vitality of the glands. From the preceding character is derived another phenomenon, which may be conſidered peculiar to the glandular ſyſtem; *viz.* that it is in general more active in winter than in ſummer, in cold than in warm climates. Warmth, by relaxing the integuments, increaſes the cutaneous diſcharge at the expence of that of the glands; while the action of cold is the inverſe of the preceding. Hence the ſame fluid, introduced into the body, is expelled in ſummer by the ſkin, in winter by the kidnies.

5th *Character.*—Influence of ſex on the vital properties of the glands. Is the vitality of theſe organs more active in the male than in the female? In thoſe which are ſubſervient to digeſtion, the lacrymal and urinary ſecretion, &c. the two ſexes exhibit very little difference. In the generative ſyſtem, the male poſſeſſes the addition of teſticles and proſtate, the female of mammary glands; ſo that here there is a compenſation. But the influence of the former on the animal economy very much exceeds in its force that of the latter.

Developement of the Glandular Syſtem.

1. *State of this ſyſtem in the fœtus.*—Although the ſecre-

tions poſſeſs very little activity in the fœtus, the glands in general are large. The ſalivary glands and pancreas are larger than in the ſequel: the bulk of the liver is enormous; and the kidnies conſiderably exceed their adult volume. It is not yet aſcertained whether the ſame obſervation applies to the mucous glands. The form and colour are different in ſeveral from what they afterwards exhibit. The texture partakes of that ſoftneſs and delicacy, which are common to the whole body; and they abound with fluids. In reſpect of their ſecretions, they ſeem to be in a condition analogous to that of remiſſion in the adult: indeed, they produce ſtill leſs than at that time. In fact, all the reſervoirs would not ſuffice to contain the produce of their ſecretion, if theſe were as much produced in a given time, as after birth. Is this becauſe the black blood, which they contain, does not furniſh ſuitable materials? or rather, becauſe the actions concerned in the compoſition of the body predominate ſo remarkably over thoſe of the other kind? All the matter brought to the organs remains in them, and affords the materials of the rapid growth, which is then taking place: conſequently, the ſecretions, which are deſigned chiefly to get rid of the reſidue of nutrition, are then inactive. Moreover, digeſtion introduces into the blood none of thoſe principles, which, not being required for nutrition, are expelled nearly as they enter, without having belonged to the compoſition of the organs; ſuch as the greateſt part of the drink.

2. *State of the glands during growth.*—This ſyſtem acquires a ſudden increaſe of energy at the time of birth. Red blood now circulates through its veſſels; and the extremities of the excretories are ſtimulated in various ways, as, by the food in the caſe of thoſe which open on the alimentary canal, by the air in the reſpiratory apparatus, &c. The organs are ſo much the more ſenſible to this ſudden excitation, in proportion as they were before unaccuſtomed to it. Yet many of the ſecretions are carried on with leſs activity during the firſt years of life, than in the ſequel, as thoſe of the ſalivary glands, liver, &c. Affections of the glandular ſyſtem are not the leading ones in the firſt years of life. The lymphatic *glands*, as they are called, and not the parotids, form the ſwellings ſo frequent about the neck. Hepatic affections are rare at this time. All the ſecretions connected with the generative proceſs hitherto do not exiſt. The organs, which are particularly employed at any age, are chiefly affected by acute and chronic diſeaſes at that time; while thoſe, by which no important function is exercifed, ſeem to be overlooked. All affections of the teſtis and chord are unfrequent before puberty, while the proceſs of nutrition alone is carried on in theſe organs. The glandular tiſſue is for a long time ſoft and delicate in the child; and it has not that property of becoming hard in conſequence of boiling, which we have mentioned as belonging to it in the adult.

3. *State of the ſyſtem after growth.*—We have already ſpoken, in the article Generation, of the organs which come into activity at puberty, and of the influence which they exert on the frame. At this time all the ſyſtem acquires a greater firmneſs in its texture. Towards the fortieth year the digeſtive glands ſeem to be predominant in the economy, and the liver is eſpecially obſervable among thoſe. Now bilious affections are moſt numerous; and the influence of thoſe paſſions, to which the bilious temperament ſeems to diſpoſe, is moſt obſervable.

4. *State of the glands in old age.*—At this time the organs gradually become more hard in their texture: but their colour changes leſs than that of moſt parts. The liver, kidney, &c. are nearly as full of blood as in the adult; while the muſcles, pale and colourleſs, contain a ſmaller proportion than before. It ſeems that this fluid firſt quits the ſkin and muſcles, which are fartheſt from the heart, and is concentrated in the nearer organs: thus the ſecretions are ſtill abundant in old perſons, while the muſcular and nervous powers are conſiderably weakened. The kidnies and liver ſtill ſeparate their particular ſecretions in large quantity. The activity of the generative ſyſtem has long ceaſed. The active exertion of the glands which are ſtill employed may be referred to two cauſes. The decompoſition of the body is very marked at this time, and much matter is conſequently thrown out by certain glands. The decay of the old ſubject is a phenomenon exactly oppoſite to that of growth in the fœtus. The ſkin, ſhrivelled and hardened, ceaſes to throw out the products of decompoſition, and the glands ſupply its place.

Generally ſpeaking, life ceaſes moſt gradually in the glandular ſyſtem. In the bodies of old perſons we ſee the gall and the urinary bladders ſtill full of their reſpective fluids. Compreſſion of any gland, even of the proſtate, ſhews that it contains much fluid; even more than we obſerve in the young ſubject. It is alſo a remarkable phenomenon that all the chief internal organs, as the liver, kidney, heart, lungs, &c. ſtill preſerve a conſiderable ſhare of vitality, while the parts ſubſervient to ſenſation and locomotion are nearly exhauſted, and the ties, which connect the individual to ſurrounding objects, are conſequently nearly deſtroyed. Haller, Element. Phyſiolog. tom. 2. Dumas, Principes de Phyſiologie, t. 4. Bichat, Anatomie Generale, t. 4.

Gland, in *Vegetable Phyſiology*, (*glandula*, a little kernel,) is defined by Linnæus as "a ſmall tumour, diſcharging a fluid." This fluid is always ſome peculiar ſecretion. The calyx and ſtalks of the Moſs Roſe, and of many other Roſes in ſome degree, are covered with prominent glands, diſcharging a viſcid aromatic liquor. Between the ſerratures of the leaf of *Salix pentandra*, the Bay-leaved Willow, is a ſeries of ſuch glands, whoſe exudation is a highly fragrant yellow gum-reſin, to which the fine-ſcent of that leaf is chiefly owing, and ſeveral other Willows are provided with ſimilar, though leſs perfumed, ſecretions. On the footſtalks of the Guelder-roſe, *Viburnum Opulus*, are very large and elaborate glands, whoſe diſcharge however is comparatively trifling, while various ſpecies of Paſſion-flower bear cup-ſhaped glands, on their footſtalks, producing a conſiderable quantity of very ſweet honey. Theſe therefore bear more analogy to thoſe glands, appropriated to ſome flowers, and called, from their produce, nectariferous glands, or nectaries. Such occur in *Geranium*, and in the Cruciform plants, conſtituting the Linnæan claſs *Tetradynamia*. In the latter the nectariferous glands occaſionally exhale a powerful ſcent, eſpecially in *Siſymbrium tenuifolium*, Engl. Bot. t. 525.

The kinds of glands above-mentioned, being of a ſecretory nature, certainly bear a great analogy to the glands of the animal body, but it appears that the more general and important ſecretions of vegetables are accompliſhed through membranes, whoſe organization and phyſiology are inſcrutable to our powers of inveſtigation. S.

Glands *of Birds and Fiſhes.*—See *Anatomy of* Birds, and Fish.

GLANDEN, in *Geography*, a town of Pruſſia, in Natangen; 30 miles E. of Brandenburg.

GLANDERS, in *Veterinary Science*, a filthy diſeaſe in a horſe, ſo called, probably, from the ſwelling of the ſubmaxillary glands that accompanies it; and conſiſting in a corrupt ſlimy matter, running from the noſe, of a different colour, according to the degree of the malignity, or as the infection has been of a ſhorter or longer continuance; being white, yellow, green, or black, ſometimes tinged with blood.

Authors aſcribe it to various cauſes: ſome to infection; ſome to a diſorder of the lungs; others to the ſpleen; ſome to the liver; and others to the brain. After it has been of ſo long ſtanding, that the matter is of a blackiſh colour, which is uſually in its laſt ſtage, they ſuppoſe it to come from the ſpine; and hence they call it the *mourning of the chine.*

Kernels and knots are uſually felt under the caul in this diſorder; and as theſe grow bigger and more inflamed, ſo the glanders increaſe more. The progreſs of the diſeaſe is extremely uncertain; as ſome horſes will endure it for many years, without any other obvious inconvenience than a ſlight diſcharge and the enlargement of the glands under the jaws; and inſtances have occurred in which theſe ſymptoms have diſappeared for ſeveral weeks, and returned, perhaps, with no augmented virulence. In moſt caſes, however, the courſe of the malady is more rapid; the bones and cartilages of the noſe are ſpeedily eroded by the malignity of the ulcers, from which an abſorption commences, and conveys the poiſon into the circulation, gradually and fatally contaminating the whole frame. Neither the appetite nor the condition of the glandered horſe ſuffers materially in the early or mild ſtage of the complaint. When, however, it has ſpread its dominion over the thoracic viſcera, forming ulcers in the ſubſtance of the lungs and in the wind-pipe, great pain and difficulty of reſpiration are experienced, the diſcharge becomes very conſiderable, the appetite is injured, and the body of the unfortunate animal exhibits a picture of extreme diſtreſs; and unleſs the humanity of the owner does not induce him to terminate his ſufferings, the diſeaſe will, by tardy ſteps, afford relief to the wretched animal by diſſolution.

M. La Foſſe, farrier to the king of France, has taken great pains, by repeated diſſections, to diſcover the ſource and cauſe of this diſorder, and to aſcertain the proper and effectual method of cure. He has diſtinguiſhed ſeven different kind of glanders, four of which are incurable. The firſt proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is diſcharged through the noſtrils, like a whitiſh liquor, appearing ſometimes in lumps and grumes: the ſecond is a waſting humour, that uſually ſeizes horſes at the decline of a diſeaſe cauſed by too hard labour, and proceeds from the lungs: the third is a malignant diſcharge, which ſometimes attends the ſtrangles, falls upon the lungs, and is diſcharged at the noſtrils: the fourth is when an acrimonious humour in the farcy ſeizes theſe parts: the fifth ariſes from a horſe's taking cold: the ſixth is a diſcharge from the ſtrangles, which ſometimes vents itſelf at the noſtrils: the ſeventh, or real glanders, is that above deſcribed.

M. La Foſſe, after examining, by diſſection, the carcaſes of glandered horſes, and making a ſtrict ſcrutiny into the ſtate of the viſcera, aſſiſted in his enquiry by ingenious anatomiſts for the ſpace of ten years, affirms this diſeaſe to be altogether local, and that the true ſeat of it is in the pituitary membrane which lines the partition along the inſide of the noſe, the maxillary ſinuſſes or cavities of the cheek-bones on each ſide of the noſe, and the frontal ſinuſſes or cavities above the orbits of the eyes; that the viſcera, as the liver, lungs, &c. of glandered horſes are, in general, very ſound; and, therefore, that the ſeat of the diſorder is not in thoſe parts, as many authors have aſſerted.

He found theſe cavities more or leſs filled with a viſcous ſlimy matter; the membrane, which lines both them and the noſtrils, inflamed, thickened, and corroded with ſordid ulcers, which, in ſome caſes, had eat into the bones. He obſerves, that, when glandered horſes diſcharge matter from both noſtrils, both ſides of the membrane and cavities were affected; but when they ran at one noſtril only, that ſide only was found diſtempered; and if one gland only was affected the horſe diſcharged from one noſtril only: but if both were affected, the diſcharge was from both. It has been obſerved, that the glanders in horſes very much reſembles a diſorder in men, called *ozena.*

In this diſeaſe, if the matter ſticks to the inſide of the noſtrils, like glue or ſtiff paſte; if the inſide of the noſe is raw, and appears of a livid or leaden hue, and the matter becomes bloody, fœtid, and of an aſh-colour; theſe ſymptoms are very unfavourable; but when only a limpid fluid is firſt diſcharged, and afterwards a whitiſh matter, the gland under the jaw does not much increaſe, and the diſorder has been of no long continuance, a ſpeedy cure may be expected. The cure of the milder kind of glanders may firſt be attempted by injections and fumigations. When theſe latter ſymptoms appear, the horſe ſhould firſt be bled, and treated as in the common diſorder of cold; and then, let an emollient injection, prepared with a decoction of linſeed, marſh-mallows, elder, chamomile flowers, and honey of roſes, or ſuch like, be thrown up as far as poſſible with a ſtrong ſyringe, and repeated three times a day: if the running is not leſſened or removed in a fortnight by theſe means, a reſtringent injection may be prepared with tincture of roſes, lime-water, &c. and the noſtrils fumigated with the powders of frankincenſe, maſtic, amber, and cinnabar, burnt on an iron heated for that purpoſe, the fumes of which may eaſily be conveyed through a tube into the noſtrils. When the diſeaſe is inveterate, recourſe muſt be had to the operation of trepanning, which M. La Foſſe performed on three horſes, two of which diſcharged from one noſtril only, and the third from both: he trepanned the two firſt on that ſide of the head which was affected, and the other on both ſides, and found that the wound and perforation filled up with good fleſh in twenty-ſix days, and the horſes ſuffered no inconvenience from the operation. The method of performing this operation will be underſtood by means of *Plate* XIX. *Miſcellany, fig.* 1, and the following explication: B, B, are two lines repreſenting the bounds of the cerebellum, or back part of the brain, which commences from the line D. C C is a line, where the ſuperior part of the ſinus frontalis commences, together with a view of the bottom of the ſinus, terminating between the lines D and E, where appears a ſubſtance in the form of a pear, which is the os ethmoides, or ſieve-like bone through which the olfactory nerves paſs, communicating ſenſibility to the pituitary membrane. E repreſents the beginning of the maxillary ſinus, terminating at M: the ſhaded ſpace between theſe lines repreſents the great cavities. F is a bony partition, ſeparating this ſinus into two parts that have no communication: of which partitions there are ſometimes two, repreſented by F and G. Some horſes have neither of theſe. N ſhews the place of the cornets or horns; O, the redoubling; P, their middle part; Q, the lower part of them: and M, the bony pipe or canal which guards the maxillary nerve: A A is the ſeptum narium, dividing the noſe from top to bottom, and ſeparating the two noſtrils; L ſhews the place where the trepan ſhould be applied, when there is reaſon to apprehend that the glanders is ſpread into the frontal ſinus; E is the place where it ſhould be applied to cleanſe the maxillary ſinus, though the round ſpot between D and E is preferable, becauſe one orifice in this place will ſerve to waſh all the parts, both above and below, with one injection. H ſhews the place where another perforation ſhould be made, as a drain for diſcharging the foul matter waſhed away by the injection; and this hole, kept open by a hollow leaden pipe, would, in all recent caſes, be ſufficient. I repreſents the injection thrown in by the ſyringe, which flows out by the orifice and the noſtril K; and, during this part of the operation, the noſtrils ſhould be held cloſe. If there ſhould be two bones in the maxillary ſinus, it is abſolutely neceſſary to pierce through both, with a ſtiletto or ſharp-pointed tuck, as in the figure. The trepan ſhould be directed towards the interior part of the noſe, to prevent its being obſtructed by the roots of the teeth. R is the trepan, S the handle which turns it, and T the ſaw-part to be applied to the bone. The ſurgeon's trephine will anſwer the purpoſe for this operation; but before the inſtrument is applied, a circular piece of the ſkin, of about the ſize of half a crown, ſhould be firſt cut off with the membrane which covers the bone. The ſyringe ſhould be large enough to contain half a pint of injection. The injection firſt uſed ſhould be of a deterſive nature, as a decoction of birth-wort, gentian, and centaury, to a quart of which may be added two ounces of Egyptiacum and tincture of myrrh; and when the diſcharge abates, and the matter becomes of a thick conſiſtence and white colour, this injection may be changed for barley-water, honey of roſes, and tincture of myrrh; and for completing the cure, Bates's alum-water, or a ſolution of colcothar, vitriol, lapis medicamentoſus, and ſuch like, in lime-water, will ſerve to dry up the moiſture, and to reſtore the tone of the relaxed glands. For this purpoſe Dr. Bracken recommends the following mixture: Take of alum and white vitriol powdered, of each four ounces; calcine them in a crucible; when cold, powder the calx, and mix it with a gallon of lime-water and a quart of vinegar, and decant the mixture clear for uſe. The perforations that are made in this operation ſhould be kept open, after the uſe of the injection, by fitting to the upper one a piece of cork waxed over, and a hollow leaden tent to the lower, through which there will be a conſtant drain of matter from the ſinuſes; and both may be ſecured by a proper bandage. The growth of the fleſh ſhould be alſo checked by rubbing with cauſtic medicines, or applying the actual cautery. The cure will be expedited, by giving every day a quart or three pints of a ſtrong decoction of guaiacum chips, by purging at proper intervals, and putting a rowel into the horſe's cheſt: and if theſe fail, mercurials may be adminiſtered with the phyſic, and the alterative powders with lime-water may be given and continued for ſome time.

The following remedy is ſaid to have ſucceeded, in fifty caſes out of ſixty, for curing the glanders, without trepanning. Keep the horſe a day or two with ſmall quantities of choice hay, and ſcalded bran; then blow up his noſtrils as much aſſarabacca, in fine powder, as will lie on a ſix-pence, evening and morning, giving him for drink ſmall lime-water, during four or five days: then boil two ounces of elecampane roots in a quart of drink, till they mix, and give it once a day during three or four days more; then boil two handfuls of the white moſs that grows on oaken pales, in two quarts of milk, till one is conſumed; ſtrain it and ſqueeze the moſs, and give the milk juſt warm: repeat this for four or five days: about an hour after the horſe has had his drink each day, take a piece of ſweet butter, about the ſize of an egg, and about half an ounce of brimſtone finely powdered, and work them well together; then take two clean gooſe feathers, as long as they can be procured, and make a hole in each of the quill ends, in which faſten two long threads; then anoint the feathers well with the mixture, and roll them in dry flour of brimſtone: open the horſe's noſtrils, and thruſt the feathers up into his head, faſtening the threads to the top of his head, to prevent their dropping out: ride him an hour or two morning and evening, and let him ſtand half an hour after he returns to the ſtable before the feathers are taken out: purſue this courſe eight or nine days, bathing his head with camphorated ſpirits of wine, and afterwards confining his head over a tub of hot grains, that he may breathe the ſteam. A rowel may prevent a relapſe.

After all that has been ſaid, it is now generally allowed, that no effectual remedy for the glanders has yet been diſcovered. The operation of trepanning has never been attended with permanent ſucceſs; and whatever relief has been obtained from the uſe of various medicines, it has been merely temporary, and the diſeaſe has been pronounced incurable. But though all attempts for curing the glanders have hitherto proved ineffectual, the inquiry ſhould be purſued, and efforts for this purpoſe ſhould be renewed till the veterinarian's ingenuity and perſeverance are crowned with ſucceſs. The analogy ſubſiſting between the glanders and the venereal diſeaſe has led ſome practitioners to recur to the uſe of mercury, but the ſucceſs attending it has been very partial. Profeſſor Coleman mentions a ſingle caſe which occured at the Veterinary College, in which the glanders yielded to the treatment employed, which was that of repeated and long-continued doſes of calomel, carried to the extent of ſalivation. This ſolitary caſe led to many trials of a ſimilar nature, but, unhappily, without the ſucceſs which was hoped for by the profeſſor, who exerted his wonted ingenuity to improve the hint which this ſingle inſtance afforded. Others have made ſimilar efforts in this way, with only a temporary abatement of the ſymptoms, but without ultimate ſucceſs. Some years ago, great expectations were formed, from the uſe of the mineral acids in the venereal diſeaſe; and trials were made with theſe in ſome caſes of glanders, which were ineffectual. The late profeſſor of the Veterinary College, M. St. Bel, made a variety of experiments for aſcertaining the nature of this diſeaſe, and for inveſtigating an effectual remedy, whilſt he was profeſſor of the veterinary ſchool at Lyons; he has recorded the caſes that fell under his notice, with his method of treatment, which was very diverſified and multifarious; but he concludes with obſerving, "notwithſtanding my failures, I think that a remedy may be found for the glanders." Many circumſtances convinced M. St. Bel, that the virus of the glanders has greater activity in ſouthern than in northern countries; and that its progreſs is more rapid in the mule and the aſs, than in the horſe; but that the former are not ſo ſubject to receive it by infection or contact as the horſe is. The uſe of verdigris having been recommended by a profeſſor of the veterinary art, Mr Lawſon, ſurgeon to the Oxfordſhire light dragoons, gave this medicine a trial in two caſes, thoſe of a horſe and mare, beginning with one drachm daily, and gradually increaſing it to one ounce. But no beneficial effect was produced. Diſſection of the horſe after three months' trial ſhewed no diſeaſe in the brain, but it was altogether confined to the ſeptum of the noſe and noſtrils.

As the glanders is a diſeaſe of ſuch virulence, known to be contagious in a high degree, and hitherto found to be incurable, it is of importance to diſtinguiſh it from other diſeaſes to which the horſe is ſubject. A cold, which has been ſometimes miſtaken for the glanders, may be eaſily diſtinguiſhed from them. In colds, there is generally a certain degree of fever, the eyes appear dull or watery, the appetite is diminiſhed, and there is almoſt always a cough. If the glands of the throat ſhould ſwell, they are not ſo cloſely attached to the jaw-bone as in the glanders, but feel looſe and moveable under the ſkin; they are alſo generally in a ſtate of active inflammation, feeling hot, and ſofter than in the glanders. In colds, both noſtrils are almoſt always affected; in the glanders it frequently happens that the diſcharge is only from one. In colds, the noſtrils are not ulcerated; in glanders this always happens, though at different periods of the diſeaſe. The ſtrangles have been ſometimes miſtaken for the glanders; but in this diſeaſe the inflamed glands very ſoon ſuppurate and burſt, by which all the other ſymptoms are generally removed, whilſt in the glanders the glands ſeldom or never ſuppurate. In order, however, to avoid all danger, it is adviſeable, as ſoon as a horſe is perceived to have a diſcharge from his noſe, to put him into a ſtable, where he can have no communication with other horſes. If the glands of the throat be enlarged and inflamed, apply a large poultice to them, ſteam the head three or four times a day, let the horſe be well clothed, and give a fever powder every day, or once in 12 hours. By theſe means, the diſeaſe, if it ariſe from a cold, will ſoon be removed. When conſiderable ulceration is perceived in the noſe, with the other concomitant ſymptoms of the glanders, the ſooner the horſe is deſtroyed, the better.

The moſt effectual method of purifying ſtables in which glandered horſes have been kept, is to remove, or carefully ſcrape, and afterwards ſcour with ſoap, ſand, and boiling water, every thing on which the horſe may have depoſited any matter, and afterward to cover every part of the ſtable with a thick coat of lime and ſize. It is a common practice with the owners of horſes, when they have had any one of them ſeized with the glanders, to bleed and purge the reſt, by way of prevention; but this method will ſerve rather to promote than prevent the diſeaſe, as it will conſiderably increaſe the action of the abſorbent veſſels, by which action the glanders are conveyed into the ſyſtem.

GLANDIUM, in *Surgery*, a name ſometimes given to an excreſcence near the anus.

GLANDORE, in *Geography*, a harbour of the ſouth of Ireland, in the county of Cork: it is a little to the weſt of Roſs, and has the village of Myros at the extremity of it.

GLANDORP, Matthias Louis, in *Biography*, a phyſician, was born at Cologne in 1595. He ſtudied firſt at Bremen, in Lower Saxony, whence his family originated, and afterwards returned to Cologne, where he commenced his medical purſuits; but, by the advice of his father's friends, he was ſoon ſent to Padua, in order to reap the benefits of ſtudying under the great maſters, who at that time were ſo diſtinguiſhed in medicine. He attached himſelf particularly to Fabricio and Spigelius; and he made ſuch great progreſs in anatomy under the latter, that he was deemed qualified to give public demonſtrations. Before returning to Germany, he received the degree of doctor in 1618. He determined to fix himſelf at Bremen, in which city he found every thing favourable to his views; and his ſucceſs in practice gained him ſo much reputation, that he was elevated to the moſt honourable offices. He was phyſician to the archbiſhop and to the republic, when he died in 1640. He left ſeveral works, adorned with plates, which contain many important obſervations on anatomy. Theſe are, 1. "Speculum Chirurgorum, in quo quid in unoquoque vulnere faciendum, quidve omittendum, præmiſſâ partis affectæ anatomicâ explicatione, obſervationibus ad unumquodque vulnus pertinentibus adjectis, conſpicitur ac pertractatur," Bremæ, 1619, 8vo. This was republiſhed in 4to. 1628, with theſe two treatiſes, 2. "Methodus medendi paronychiæ, cui acceſſit decas obſervationum:" and, 3. "Tractatus de Polypo, narium affectu graviſſimo."—4. "Gazophylacium polypluſium fonticulorum et ſetonum reſeratum," ibid. 1633, 4to.—London 1633, 4to.—He made frequent uſe of the actual cautery in the treatment of the moſt common diſorders. The whole of Glandorp's works were collected and printed in London, in 4to. in the year 1729, under the title of "Opera omnia, nunc ſimul collecta, et plurimum emendata." This collection includes alſo ſome curious tracts on Roman antiquities. Eloy. Dict. Hiſt.

Glandorp, John, a learned philologiſt, who flouriſhed in the middle of the 16th century, was born at Munſter. He ſtudied under Melancthon, and became very diſtinguiſhed for his critical knowledge. He was elected rector of the college at Hanover, but, upon ſome diſpute, he quitted in 1555, and retiring to Goſlar, was followed by moſt of his ſcholars. In 1560, he was made profeſſor of hiſtory at the univerſity of Marpurg. He died in 1564. His works are "Sylva Carminum Elegiacorum;" "Deſcriptio Gentis Antoniæ;" "Familiæ Juliæ Gentis;" "Diſticha Sacra et Moralia;" "Annotat. in Jul. Cæſaris Comment.;" "Annotat. in Ciceronis Epiſt. famil.;" "Onomaſticon Hiſtoriæ Romanæ."

GLANDULA, in *Anatomy*, the ſame as gland.

The word is a diminutive of the Latin *glans*, acorn; and is here uſed on account of ſome external reſemblance between the glands of the body and the fruit of the oak.

Glandula *Guidonis*, among *Surgeons*, is a tumor reſembling a gland; ſoft, ſingle, moveable, with roots, and ſeparate from the adjacent parts.

GLANDULE, in *Engliſh*, ſignifies a little gland. Thus the amygdalæ, or almonds of ears, are by ſome called glandules.

GLANDULOUS, or Glandular, ſomething compoſed of glands, or that abounds with glands.

The breaſts are glandulous bodies. The cortical ſubſtance of the brain is commonly reputed to be glandulous; though Ruyſch, from the diſcoveries made by his admirable injections, holds, that there is no ſuch thing as a gland therein.

The ancients diſtinguiſhed a particular kind of fleſh, which they called *caro glanduloſa*, or glandulous fleſh.

Glandulous *Body*, *glanduloſum corpus*, more particularly denotes the proſtata.

Glandulous *Roots*, among *Botaniſts*, ſuch tuberoſe roots as are faſtened together in large numbers by ſmall fibres or threads.

GLANIS, in *Ichthyology*, a ſpecies of *ſilurus*, which ſee.

GLANOVENTA, in *Ancient Geography*, a place of Britain, in the 10th Iter of Antoninus, ſuppoſed by Horſley to be Lancheſter, in the county of Durham.

GLANS, Acorn, in *Natural Hiſtory*, a fruit contained within a ſmooth but hard bark, including a ſingle ſeed; its hind-part being covered with a kind of cup, and the fore-part bare. See Acorn and Oak.

Glans *Marinus*, a name given to a genus of ſhell-fiſh, more uſually called *balanus*, and in Engliſh the centre ſhell.

Glans *Trochitifera*, a name given by Geſner, and ſome other writers, to a kind of figured foſſil, found uſually among the trochitæ and entrochi, and evidently appearing to have in ſome manner belonged to them. All the writers, who have themſelves examined the places where the trochitæ are found, have mentioned theſe under the names of glandes trochitiferæ, others under leſs determinate ones. Agricola calls them lapides informes; and Liſter, after him, rude ſtones, having impreſſions of the entrochi. See farther Philoſ. Tranſ. N° 100.

Glans *Penis*, in *Anatomy*, the rounded extremity of the organ. See Generation, *organs of*.

GLANSHAMMAR, in *Geography*, a town of Sweden, in the province of Nericia; ſeven miles N. E. of Obreo.

GLANVILL, Joseph, in *Biography*, was born at Plymouth in the year 1636, where he probably received the early parts of his education: but he purſued his maturer ſtudies at Exeter college, Oxford. He took his firſt degree in the year 1655, and removing to Lincoln college, he graduated maſter of arts in 1658, and was, about the ſame time, appointed chaplain to Francis Rous, eſq. provoſt of Eton college. The death of his patron induced him, after a very ſhort time, to return to Lincoln college, where he ſpent his time in literary and philoſophical ſtudies, till the reſtoration of king Charles II. He became acquainted with the writings of Richard Baxter, and was an ardent admirer of his preaching and religious principles. He is ſaid to have been an eager republican in politics, but, whether this be the real fact, has been much doubted. Upon the re-eſtabliſhment of monarchy and epiſcopacy, he conformed to the national church, a circumſtance that did not in the leaſt abate the eſteem which Baxter had before manifeſted for him. He became a zealous convert to the principles of the new philoſophy, in oppoſition to the ſyſtem of Ariſtotle, and publiſhed a work in their juſtification, entitled "The Vanity of Dogmatiſing or Confidence in Opinions," &c. This piece introduced him to the acquaintance of many of the perſons who afterwards formed the Royal Society. About this time Mr. Glanvill entered into orders, and was preſented to the rectory of Wimbiſh, in the county of Eſſex, and in 1662 he was inducted into the vicarage of Frome-Selwood, in Somerſetſhire. He publiſhed in the ſame year, but anonymouſly, a diſcourſe on the fundamental doctrine of the ancient eaſtern philoſophers, which he endeavoured to prove was not incompatible with revealed religion. It was entitled "Lux Orientalis: or an Enquiry into the opinion of the Eaſtern Sages concerning the Pre-exiſtence of Souls; being a Key to unlock the grand Myſteries of Providence in relation to Men's Sin and Miſery." Upon the eſtabliſhment of the Royal Society, he publiſhed his former treatiſe, corrected and enlarged, under the title of "Scepſis Scientifica; or confeſſed Ignorance in the way of Science, in an Eſſay on the Vanity of Dogmatiſing and confident Opinion." This work was dedicated to the Royal Society, and the author was almoſt immediately admitted one of its members. In 1666 he publiſhed his work, entitled "Some philoſophical Conſiderations touching the being of Witches and Witchcraft." This performance, which is ſtill regarded as a curioſity, though very little creditable to the judgment of the author, engaged Glanvill in a controverſy which laſted as long as his life. He was now preſented to the rectory of Bath, in which city he fixed his reſidence. Here he met with many opponents, who were apt to treat him but roughly, on account of his adherence to the new philoſophy, which led him to draw up a ſmall but elegant treatiſe, entitled "Plus Ultra: or the Progreſs and Advancement of Knowledge ſince the Days of Ariſtotle. In an account of ſome of the moſt remarkable late improvements of practical uſeful learning, to encourage philoſophical endeavours, &c." The author was violently attacked on this occaſion, but he defended himſelf with ſpirit and ſucceſs. His reputation was now firmly fixed, and he was frequently called upon to preach on public occaſions. At a viſitation of the dioceſe, he delivered a diſcourſe which met with general approbation, and which was frequently re-printed: it was a defence of reaſon in the affairs of religion, againſt infidelity, ſcepticiſm, and fanaticiſm of all ſorts. He next attempted to ſhew the correſpondence between religion and the new philoſophy, in a diſcourſe concerning the religious temper and tendency of the experimental philoſophy which is profeſſed by the Royal Society. "While," ſays one of his biographers, "he was entitling himſelf to the particular acknowledgments of the members of that body, by defending the reaſonableneſs and uſeful tendency of their purſuits, he alſo contributed to their collection of inſtructive and entertaining papers, ſome obſervations on the mines in the Mendip hills, and on the natural hiſtory and ſprings of Bath, which were well received, and inſerted in the Philoſophical Tranſactions." In the year 1672, Mr. Glanvill exchanged his rectory of Frome for that of Streat, in the ſame county, with the chapel of Walton annexed; and about the ſame time was made one of the king's chaplains. In 1676, he publiſhed his "Eſſays on ſeveral important Subjects in Philoſophy and Religion," conſiſting of the principal of his former pieces, reviſed and improved, with a treatiſe, entitled "Antifanatic Theology and free Philoſophy." Two years after this, his "Eſſay concerning Preaching" came out; it was written for the purpoſe of diſſuading the younger clergy from that affectation of wit and fine ſpeaking, which began to be faſhionable in thoſe times, and to recommend and enforce a plain and practical method of enforcing the moral duties of the goſpel, as the true eloquence of the pulpit. The laſt work of this worthy divine, was entitled "The zealous and impartial Proteſtant, ſhewing ſome great but leſs heeded Dangers of Popery." Mr. Glanvill died of a fever at the early age of forty-four, and Dr. Horneck publiſhed a quarto volume of Diſcourſes, &c. after his death, to which is prefixed an account of the author. As a preacher, Mr. Glanvill was eloquent and pathetic: in private life he was truly amiable and praiſe-worthy. He was author of various other tracts beſides thoſe already noticed, the titles of which are given in the Biographia Britannica. To this work the reader is referred for further particulars.

GLAREANA, in *Ornithology*, the name of a bird deſcribed by Geſner from the figure, and ſuſpected to be no way different from the ſpipoletta, a kind of lark, the Alauda *campeſtris*; which ſee.

GLAREOLA, a ſpecies of *Tringa*; which ſee.

Glareola, in *Ornithology*, a genus of the Grallæ order, founded on the natural family called by Briſſon "Perdrix de Mer," and alſo Glareola. The character of this genus conſiſts in the bill being ſtrong, ſhort, ſtraight, and turned down or hooked at the tip; noſtrils linear, and placed in an oblique poſition at the baſe of the bill; gape of the mouth large; feet four-toed, the toes long, ſlender, and connected at the baſe by a membrane; tail furcated, and containing twelve feathers. The number of ſpecies, according to Gmelin, are three, namely, Auſtriaca, Senegalenſis, and Nævia, the firſt of which, however, compriſes ſeveral remote varieties. Linnæus deſcribed this as a ſpecies of hirundo, the ſecond kind is a tringa of the ſame author, and the third, a gallinula of Ray.

Species.

Austriaca. Above grey-brown; collar black; chin and throat white; breaſt and belly reddiſh-grey. Gmel. *Hirundo marina*, Aldr. *Hirundo riparia*, Merg. *Pratincola*, Kram. *Gallinula erythropus minor*, Geſn. *Perdrix de mer*, Buff. *Sea ſwallow of Aldrovandus*, Will.

The length of this bird is nine inches; the bill black, with the baſe red; upper wing-coverts whitiſh; quill and tail-feathers duſky, the outer ſide of the firſt tail-feathers white; and the legs and naked part of the thighs in general red. The ſpecies inhabits chiefly the ſouth of Europe, and the milder parts of Aſia; towards the north it becomes more ſparingly diffuſed, and is very rarely ſeen ſo remote from the ſouthward as Britain. It abounds moſt in the plains of the deſerts towards the Caſpian ſea, in the neighbourhood of the rivers, its food conſiſting of aquatic inſects and worms.

One of the varieties of this ſpecies is called by Briſſon Glareola torquata, and by Buffon, "Perdrix de mer à collier." The plumage beneath is white; the front black, with a white ſpot on each ſide, and the collar brown. Its ſize is rather inferior to the former, and the legs blackiſh inſtead of red. This, like the other, is a noiſy reſtleſs bird, and frequents the banks of rivers, aquatic inſects conſtituting its principal food. The eggs are oblong, and uſually about ſeven in number in each neſt.

The bird called "Perdrix de mer" by Sonnerat is another variety of this ſpecies; the lower parts of the plumage, and alſo the rump, are white; and the chin ſtreaked with black, and ſurrounded by a black curved line. This was caught in the open ſea, in the latitude of the Maldivia iſles, and lived a month on flies, and bread ſoaked in water.

Two other varieties occur in the Eaſt Indies, on the coaſt of Coromandel, and are likewiſe deſcribed by Sonnerat; the firſt of theſe is brown, the under parts, with the rump and baſe of the tail white; in the ſecond, the tail-feathers are brown, having the outer ones marked with a white band.

SENEGALENSIS. Entirely fuſcous. Gmel. *Glareola Senegalenſis*, Briſſ. *Tringa fuſca*, Linn. *Perdrix de mer brune*, Buff. *Senegal pratincole.* Scarcely exceeds the former in ſize, being nine inches and a half in length, and inhabits Senegal. The ſame variety is found alſo in Siberia.

NÆVIA. Brown, ſpotted with white; lower part of the belly and vent reddiſh-white, with black ſpots; bill and legs black. Gmel. *La perdrix de mer tachetée*, Briſſ. *Gallinula melanopus*, *Rothnuſſel*, Ray. *Giarole*, Buff. *Spotted pratincole.*

Size of Glareola auſtriaca. This variety is met with in Germany.

GLARIANUS, HENRICUS, LORITUS, in *Biography*, ſurnamed *Glarianus*, from the town of Glaris, in Switzerland, where he was born in 1488. He rendered himſelf famous by his knowledge of muſic, and belles lettres; but he may more properly be ranked among dilettanti theoriſts in muſic, than a muſician by profeſſion; and his abilities, as a ſcholar and critic, have been much leſs diſputed by the learned, than his knowledge of muſic, by muſicians.

He ſtudied at Cologn, Baſil, and Paris; his preceptor in muſic was John Cochlæus; and in literature, Eraſmus, with whom he lived in ſtrict friendſhip, and by whom he was warmly recommended, in a letter ſtill extant, to the archbiſhop of Paris. He is called by Walther a philoſopher, mathematician, hiſtorian, geographer, theologian, and poet; indeed, he diſtinguiſhed himſelf in moſt of theſe characters. Gerard Voſſius calls him a man of great and univerſal learning; and for his poetry, the emperor Maximilian I. honoured him with the laurel crown.

His famous treatiſe on muſic, is entitled ΔΩΔΕΚΑΧΟΡΔΟΝ, which implies twelve modes; to which number he wiſhed to augment the eccleſiaſtical tones, which had never before exceeded eight, from the time of St. Gregory. Zarlino, and a few more, adopted the opinion of Glarianus, but ſoon relinquiſhed it, on finding that they had made no converts. Indeed, the whole twelve modes of Glarianus contain no other intervals than thoſe to be found in the key of C and A natural, or in the different ſpecies of octave, in thoſe two keys; and though his augmentation extends the compaſs of ſounds uſed in the modes, it offers no new arrangement of intervals, as may be ſeen by his title-page, when it tells us that the authentic modes are D, E, F, G, A, C, and the plagal A, B, C, D, E, G; where we perceive that A, C, E, G, are repeated, by being made both authentic and plagal.

If, inſtead of twelve modes, Glarianus had augmented the eight to twenty-four, by aſſigning two to each ſemitone in the octave, he would have done real ſervice to the muſic of his time; but his cotemporaries were not yet ready for ſuch an innovation, being ſtill held too faſt in the trammels of the church to dare uſe any other ſounds than thoſe which time had conſecrated, and authority admitted within its pale.

His book, however, contains many curious anecdotes and compoſitions of the greateſt muſicians of his time, which were excellent ſtudies for his countrymen and cotemporaries, and, if ſcored, would be ſtill very inſtructive and uſeful to young contrapuntiſts. Glarianus died 1563, aged 75.

GLARIS, or GLARUS, in *Geography*, a canton in Switzerland, formerly ſubject to the abbeſs of the convent of Seckinguen, in Suabia, but poſſeſſing a democratical form of government, under a mayor, appointed by the abbeſs, but choſen by the inhabitants; till towards the latter end of the thirteenth century, the emperor Rodolph I. obtained the excluſive adminiſtration of juſtice; and ſoon afterwards his ſon Albert purchaſed the mayoralty, which had become hereditary, and reunited in his own perſon the whole civil and judicial authority. The government of Albert, and of his deſcendants the dukes of Auſtria, was arbitrary and oppreſſive; and therefore, in 1350, Schweitz, aſſiſted by Zuric, Lucerne, Uri, and Underwalden, expelled the Auſtrians from the canton of Glarus, and re-eſtabliſhed the democracy. Glarus then entered into a perpetual alliance with its deliverers, and was received into the Helvetic confederacy, with ſome reſtrictions, which were not aboliſhed till 1450. It was then the 6th canton, but afterwards became laſt in rank of the eight ancient cantons, as they were called. The people of Glarus enjoyed their liberties unmoleſted till 1388, when the Auſtrians made an irruption into the canton, and pillaged the country and maſſacred the inhabitants. At this time 350 troops of Glarus, aſſiſted by 30 Switzers, reſiſted the whole ſtrength of the Auſtrian army, and compelled them to retire. In the 16th century the reformation was introduced into this canton; but the Proteſtants and Catholics have been accuſtomed to live together on terms of mutual toleration and friendſhip: of late the number of Proteſtants has very much increaſed, and their induſtry in every branch of commerce is obſerved to be far ſuperior to that of the Catholics. The government of this canton, previouſly to the French revolution, was entirely democratical; every perſon at the age of 16 had a vote in the "Landſgemeind," or general aſſembly, which was annually held in an open plain. This aſſembly ratified new laws, laid contributions, entered into alliances, declared war, and made peace. The "Landamman" was the chief of the republic, and was choſen alternately from the two ſects; with this difference, that the Proteſtant remained three years in office and the Catholic two. The other great officers of ſtate, and the bailiffs, were taken alſo by lot from a certain number of candidates propoſed by the people. The executive powers were veſted in the council of regency, compoſed of 48 Proteſtants and 15 Catholics; and each ſet had its particular court of juſtice. This canton comprehends 336 ſquare miles; and its population is eſtimated at 16,000 perſons; its contingent to the army, under the old government, was 400 men. According to the diviſion of Switzerland into 18 departments or cantons, in 1798, the canton of Glarus, together with the bailliages of Wallenſtadt, formed the canton of Linth; but according to the conſtitution of the 29th of May 1801, Glarus, together with the bailliages of Sergans, Werdenberg, Guſten, Uznac, and Rappenſchwell, forms the eighth canton, and deputes five repreſentatives to the diet.

This canton is entirely encloſed by the Alps, except towards the north; and there is no entrance but through this opening, which lies between the lake of Wallenſtadt and the mountains ſeparating this canton from that of Schweitz. At this entrance, the canton reaches from the banks of the Linth to the fartheſt extremity of its Alps, about 30 miles; forming a valley, which becomes narrower as you advance, and is ſcarcely more than a muſket ſhot in breadth at the burgh of Glarus. It afterwards opens by degrees, and, about a league from this burgh, is divided by the Freyberg mountains; at the point of this diviſion, the two rivers, Linth and Sernft, unite. The hillocks of the Peak in Derbyſhire, ſays Mr. Coxe, are mere mole-hills to the Alps of Glarus. Theſe ſtupendous chains of rocks are abſolutely perpendicular, approach one another ſo near, and are ſo high, that the ſun may be ſaid to ſet, even in ſummer, at four in the afternoon. On each ſide are a number of waterfalls, which excite attention. The valley terminates in an amphitheatre of mountains, and the glaciers of the canton cloſe the view. (See Linth.) All the houſes in this canton, like thoſe of Appenzel, are built of wood; large, ſolid and compact, with great pent-houſe roofs, that hang very low, and extend beyond the area of the foundation. The police in this democratical ſtate is well regulated; nor does liberty often degenerate into licentiouſneſs. Cattle, cheeſe, and butter conſtitute the principal commerce of the canton. The cattle are fed in ſummer upon the Alps; it is computed that 10,000 head of large cattle, and 4000 ſheep, are paſtured during that ſeaſon upon the mountains belonging to the canton. The inhabitants alſo manufacture linen and muſlins. Among the exports, a conſiderable article is ſlate, with which the canton abounds; the principal quarry being in the valley of Sernft, where large ſlates are dug up that ſerve for tables. Theſe quarries once furniſhed Great Britain with ſlates for writing; but this branch of trade has been ſuperſeded by the great ſlate quarries in Caernarvonſhire. A great part of this canton conſiſts of mountains, rocks, inacceſſible foreſts, and barren heaths, covered with ſnow; and it is ſubject to frequent inundations, and to the devaſtations occaſioned by tempeſts and falling rocks.

GLARNISH, a mountain of Switzerland; 7 miles W.S.W. of Glarus.

GLARUS, or Glaris, the capital of the above-deſcribed canton, ſituated upon the Linth. The town is large and populous; and the town-houſe is a handſome ſtructure; 52 miles E. of Lucerne. N. lat. 26° 58'. E. long. 9° 3'.

GLASENDORF, a town of Bohemia, in the circle of Konigingratz; 6 miles N.N.W. of Trautenau.—Alſo, a town of Sileſia, in the province of Neiſſe; 11 miles S.W. of Patſchkau.

GLASGOW, a very populous, handſome, and regularly built city, in the county of Lanark, in Scotland; ſituated on the north bank of the river Clyde, which is navigable for veſſels of 100 tons and upwards. In ancient times, and during the prevalence of the Roman Catholic religion, Glaſgow was chiefly diſtinguiſhed as an archiepiſcopal ſee, and was of courſe principally under the influence of the archbiſhop and his inferior clergy. Their power ſeems in thoſe days to have been civil as well as eccleſiaſtical, for the charters of the moſt ancient corporate bodies are held by this tenure, the civil magiſtrates being only noticed as of ſubordinate rank and authority, and the freedom fines, and other emoluments are expreſsly appropriated to eccleſiaſtical purpoſes. The revenue of the dioceſe of Glaſgow, if it may be eſtimated by the extent of lands ſubject to the payment of tythes, or (as they are called in Scotland) teinds, muſt have been very great; for thoſe burthens extended over almoſt the whole of the counties of Lanark, Renfrew, Dumbarton, Ayr, Dumfries, and Galloway, comprehending the whole ſouth-weſt diſtrict of Scotland, and perhaps a moiety of the moſt fertile land in the whole kingdom. Of this enormous revenue, ſince the reformation a ſmall part, but now of great value, has been appropriated for the ſupport of the univerſity of Glaſgow, ſome part for the payment of the parochial ſtipends, and a great part has reverted to the freeholders or their dependants, and theſe are conſtantly fluctuating as in other parts of the kingdom. The inſurrections and civil wars, which devaſtated Scotland ſubſequently to the reformation, and previous to the revolution, having diveſted Glaſgow of all that attraction which it had acquired as the archiepiſcopal and occaſionally as the royal reſidence, it appears to have been only remarkable as the occaſional ſcene of thoſe ſanguinary and ferocious conteſts for which the age was conſpicuous. It fell into the hands of the regent upon the defeat and flight of the unfortunate Mary Stewart at the battle of Langſide, two miles ſouth of the city. It was long afterwards battered and taken by Cromwell's army, and it was the refuge of the defeated party, after the battle of Bothwel bridge, fought between the regent (afterwards James II.) and the Covenanters. After the revolution it ſeems for many years to have been a place of little importance, poſſeſſing neither a ſufficient degree of wealth or refinement to render it conſpicuous for elegance or luxury, nor ſuch ſecurity or ſtrength as to make it deſirable or important as a military poſt. At the time of the Union with England, its whole population was eſtimated at only 14,000, a fact ſtated in the houſe of commons by Mr. ſecretary Dundas, (now lord Melville,) in one of the debates when the Iriſh Union was in contemplation. Subſequently to the Union, the riſe of Glaſgow in commercial importance, even under the ſucceſſive checks of the two civil wars in 1715 and 1745, of the vaſtly greater commercial embarraſſment, occaſioned by the ſuſpenſion of its colonial trade during the American conteſts, and all the ſubſequent hoſtilities produced by the French revolution, has been perhaps unequalled by any other place in the empire, or perhaps in the world. Its population, under the act of 1794, including its numerous ſuburbs, was returned at 94,000, and from the concealment which was practiſed from the idle fears of ignorant people, many of whom fooliſhly imagined that *cenſus* to be the precurſor of a military conſcription, that number is ſuppoſed to be at leaſt 30,000 ſhort of the actual amount.

Different hiſtories of Glaſgow have been publiſhed. Of theſe, one publiſhed many years ago by Mr. M'Ure, one of the city clerks, was much eſteemed, but is now conſidered as obſolete. Others have ſubſequently been written by Mr. Gibſon about 1774, and recently by Mr. Denholm, about 1796.

The limits of this article neceſſarily preclude the poſſibility of entering much into detail, nor would it be either amuſing or inſtructive to the general reader. We ſhall therefore inſert what remains concerning the preſent ſtate of this great commercial and manufacturing city under the following general heads.

1. *Situation and general ſtate of the adjacent country.*—Glaſgow is ſituated on the north bank of the river Clyde, in N. lat. 55° 52′, and W. long. from the meridian of Greenwich 4° 30′. The extreme length from E. to W., including two ſuburbs, is nearly two miles, and its breadth from the cathedral or high church to the river about one mile. The lower part of the city is nearly level, and the reſt is upon the ſouthern declivity of a hill. Perhaps no city or town in Europe is, upon the whole, more regularly planned; for all the principal ſtreets are either parallel or at right angles to each other. The chief ſtreets are better paved than thoſe of London, and generally wider; all the front buildings are of fine free-ſtone, which is found in great abundance in the immediate neighbourhood. The granite, or *whin ſtone,* for paving the carriage ways, is alſo very plentiful cloſe by the town. The houſes are very large and lofty, being more generally upon the French plan, where every floor forms a ſeparate lodging, acceſſible by a common ſtaircaſe, than upon the Engliſh, where one perſon occupies the whole premiſes. The more wealthy inhabitants, however, have almoſt univerſally adopted the Engliſh taſte in building. In the old part of the town it is indeed much to be regretted that there are too few public ſtreets, ſo that an immenſe number of buildings are crowded together, many of which are acceſſible only by narrow paſſages, which are very ill calculated either for free circulation of air, admiſſion of light, or domeſtic cleanlineſs. In the modern buildings theſe inconveniences are avoided, and whatever inconvenience may remain, muſt rather be attributed to the habits or negligence of the occupants, than to want of facilities on the part of the architects.

There are many very fine public buildings in Glaſgow, the moſt prominent of which we ſhall very briefly enumerate.

Churches.—The cathedral or high church is perhaps the fineſt ſpecimen in Scotland of that ſpecies of architecture, generally denominated Gothic. It was founded in the year 1123, and conſecrated in the preſence of king David I. in 1136. This building is more ſimilar to that of Litchfield, than to any other of the Engliſh cathedrals, but it does not appear to have ever been completely finiſhed, and certainly until lately little care has been uſed for its preſervation. After the reformation it is ſaid to have narrowly eſcaped deſtruction from the miſguided zeal of the people, who confounded the building itſelf with the religious or ſuperſtitious ceremonies which they had exploded. It now contains two churches adapted to the Preſbyterian form of worſhip, and the choir is uſed as a place of interment. The burying vaults, or cemetery, were formerly occupied as another place of worſhip for the barony or country pariſh of Glaſgow; but lately a new church has been erected for this purpoſe at the oppoſite extremity of the church-yard. The great ſpire is very lofty, and in ſome degree reſembles that of Saliſbury. The church was dedicated to St. Mungo, or Kentigern, whoſe burying-place in one of the vaults is ſtill ſhewn.

The remaining churches poſſeſs in general little claim to architectural encomium or deſcription. They are ſix in number, *viz.* the college, St. Andrew's, North Weſt, Iron, St. Enoch's, and St. George's.

St. Andrew's church is a handſome modern building, of Corinthian architecture, and is very ſimilar in appearance to the church of St. Martin in the Fields, Weſtminſter.

St. Enoch's and St. George's are alſo handſome modern buildings. Beſides the eſtabliſhed or parochial churches, there are many diſſenting chapels and meeting houſes, ſome of which are very handſome and commodious.

Priſon.—This is a large and very ſtrong building, ſituated in the centre of the city, adjoining to the Exchange. The lower part is occupied by the council-chambers, and rooms for the magiſtrates and the city clerks; the middle part of the building contains the cloſe or lock-up rooms for thoſe impriſoned upon criminal charges; and the two upper floors are allotted for the reception of civil debtors. The roofs are lofty, the apartments airy, and the building, upon the whole, commodious; but it is in contemplation to erect a new priſon, with an encloſed ſpace round it, where the priſoners may have the benefit of freſh air and exerciſe, from which they are at preſent precluded.

Bridewell.—This is a large building which ſerves as a place of confinement, or penitentiary houſe, for perſons of depraved habits convicted of petty offences. It is very well regulated, and every means of encouragement afforded for reclaiming the priſoners from their vices, and promoting habits of induſtry. Many, at the period of their confinement, have thus acquired and received conſiderable ſums, beſides the expence of their ſubſiſtence, which is deducted from their earnings.

Town Hoſpital—for the reception of poor perſons unable to maintain themſelves. The expence of this eſtabliſhment is defrayed by a tax or aſſeſſment on the inhabitants, and by the proceeds of the labour of thoſe admitted, who are ſupplied with work ſuited to their reſpective abilities. The inmates are aged and infirm perſons and deſtitute children: the latter are well educated, and when arrived at a proper age, the boys are apprenticed to trades and the girls ſent to ſervice. The economy of the houſe is ſuperintended weekly by gentlemen who act in rotation. The whole is very well managed.

Royal Infirmary—a very fine modern building, from a plan of Meſſrs. Adams'. From 90 to 120 patients are generally under cure, but the houſe contains accommodation for a much larger number when required. It is ſupported by donations, legacies, and annual ſubſcriptions; the funds at preſent amount to 10,000*l.* or 12,000*l.*, beſides what has been annually expended; the annual diſburſement is about 1800*l.* or 2000*l.*; the direction is veſted in the lord provoſt, the dean of guild, convenor of the trades, profeſſors of medicine and anatomy, preſident of the faculty of phyſicians, member for the city, and eighteen directors, ten of whom are elected by the contributors, and the others by various public bodies. The directors elected by public bodies are, one by the council, one by the merchants, one by the trades, one by the univerſity, one by the miniſters of Glaſgow, and three by the faculty of phyſicians and ſurgeons. The medical aſſiſtance is afforded gratuitouſly.

Theatre Royal.—This ſuperb houſe was erected a few years ago by voluntary ſubſcriptions, upon transferable ſhares of 25*l.* each. The total coſt was upwards of 15,000*l.* part of which ſtill remains as a debt upon the property, the whole annual rent being appropriated for its gradual liquidation. The direction of the property is in ſixteen directors, four of whom go out annually, in rotation, but may be re-elected. It is unqueſtionably the largeſt and moſt magnificent provincial theatre in Britain. The managers are merely leſſees, and the leaſe is always given for a ſhort period, ſeldom exceeding two or three years.

Concert and Aſſembly Rooms.—Theſe rooms are alſo very ſplendid, and, like the theatre, were erected by voluntary ſubſcription, upon transferable ſhares.

Univerſity.—The buildings of the univerſity having been erected at various times, and in very different ſtyles, cannot be appreciated by any preciſe ſcale of architectural taſte; but the whole has certainly an air of impoſing grandeur, and is very well adapted in every reſpect to the purpoſes for which it is deſigned. It conſiſts of four diſtinct courts, which communicate with each other, and is acceſſible from the high ſtreet by three gate-ways. Behind is a very large garden laid out in graſs and ſhrubbery, with very fine walks; it is divided into three parts, of which one is appropriated as a botanical garden, another is open as a place of exerciſe and recreation for the ſtudents, and the third, in which the aſtronomical obſervatory is ſituated, is generally reſerved as a place of retirement, for the profeſſors, or of amuſement for their families and friends.

The univerſity of Glaſgow was founded in the year 1450, by William Turnbull, biſhop of the dioceſe, and then conſiſted of a chancellor, a dean of faculty, a principal, who was alſo profeſſor of theology, and three profeſſors of philoſophy.

The profeſſions and lectures are now as follow:

A lord chancellor; an office now honorary, and held for life.
Lord rector; alſo honorary—elective annually.
Dean of faculties; choſen by the profeſſors or regents.
Principal; by the crown—preſent incumbent, Rev. Dr. Taylor.

Profeſſions.	
Divinity,	appointed by the univerſity.
Church hiſtory,	crown.
Oriental languages,	univerſity
Natural philoſophy, or phyſic,	do.
Mathematics,	do.
Moral philoſophy, or ethics,	do.
Logic,	do.
Greek,	do.
Humanity, or Latin,	do.
Civil law,	crown.
Medicine,	do.
Anatomy and botany,	do.
Practical aſtronomy,	do.
Lectures.	
Materia medica,	univerſity.
Chemiſtry,	do.
Midwifery,	do.
Natural hiſtory,	do.
Elocution,	do.
Painting and drawing,	do.

The funds for the ſupport of the univerſity are in a very flouriſhing and proſperous ſtate. Independently of the emoluments derived from the ſtudents, ſalaries and commodious houſes are allotted to every profeſſor, and theſe expences are defrayed from the funds at various times granted to the univerſity: of theſe, the funds or tythes of the pariſh of Govan, form a very prominent part. The ſtudents of the five junior claſſes, *viz.* natural philoſophy, moral philoſophy, logic, Greek and Latin, are diſtinguiſhed by wearing gowns of ſcarlet freeze; the ſtudents of the ſenior claſſes have no particular diſtinction of dreſs. The reſident members of the univerſity claim an exemption from all civil burthens and ſervices, and generally from the juriſdiction of the city magiſtracy, but acknowledge that of the ſheriff of the county, and of the ſupreme courts of Scotland.

The internal government of the univerſity is veſted in the principal and profeſſors, who, in their juridical capacity, aſſume the title of regents. Their ſupreme court is a general aſſembly of the whole faculty, who, at a remote period, aſſumed the power even of capital puniſhment. The moſt ſevere ſentence, however, which has been paſſed for many years, is that of expulſion, and even this has been very rarely exerciſed. An inferior court is the "Juriſdictio ordinaria," conſiſting of at leaſt three regents, who determine offences againſt the general order and peace of the univerſity, and puniſh by a pecuniary fine. Each profeſſor alſo poſſeſſes the power of levying ſmall fines in his own claſs for negligence, contumacy, or irregularity.

The number of ſtudents in the univerſity was eſtimated at 500 thirty years ago, and this number is now greatly increaſed. The profeſſors and ſtudents, when aſſembled for the election of a rector or any other general purpoſe, are divided into four nations, according to the places of their reſpective births, *viz.*

Glotiani—comprehending the natives of Clydeſdale, and the adjacent diſtricts of Scotland ſouth of the Forth.

Transforthani—the natives of Scotland, on the north of the Forth.

Rothſiani—the natives of the weſt highlands of Scotland and of Ireland.

Loudoniani—thoſe of the eaſtern diſtricts of Scotland, of England, America, and the colonies. The votes of theſe nations are decided by a majority, and the majority of nations decides the queſtion. In caſes of parity the deciſion is in the regents.

The univerſity of Glaſgow has recently received a moſt valuable acquiſition, by the beqeuſt of the mnſeum of the late Dr. William Hunter, of London. For the reception of this valuable legacy, a very handſome building has been erected, where it is now arranged. The muſeum conſiſts of a valuable collection of paintings, chiefly original; a very fine ſelection of anatomical preparations; a cabinet of medals, and a fine library. The medals are accounted of ſuch value, that the truſtees of the Britiſh muſeum are ſaid to have offered 25,000*l.* for them, beſides furniſhing ſuch duplicates as they poſſeſſed, and defraying the expence of an application to parliament for an act, ſo far to diſſolve the teſtator's will. This liberal offer, however, was declined.

The public library of the univerſity is alſo a collection of uncommon value. It conſiſts of upwards of 6000 volumes, and many very rare and valuable manuſcripts. In the faculty hall are ſome valuable paintings, particularly one of the "Martyrdom of St. Catharine."

Among the celebrated literary characters, which have belonged to this ſeminary, the names of Dr. Cullen, Dr. Adam Smith, and the late profeſſor Miller, are moſt recently conſpicuous.

There are many other public buildings in Glaſgow, of which it will be neceſſary to confine ourſelves to very brief notices.

The *Trades-hall*—is a fine modern building from a plan of Meſſrs. Adams'. It is uſed for the general meetings of the fourteen incorporated trades, and is alſo occaſionally occupied for concerts, balls, and other public amuſements.

Merchants' Hall—is an old building, remarkable for nothing but the ſpire, which is a very fine one. It is uſed by the body to which it belongs, in the ſame manner as the Trades-hall.

Public Markets.—Theſe are very commodious, and conſiſt of ſquare-paved courts, ſurrounded by the ſtalls where the meat is expoſed to ſale. No cattle are ſlaughtered here, and they are kept very clean and regularly inſpected.

Barracks.—Theſe are ſituated in a large area walled round, and conſiſt of three very large buildings, one of which is appropriated for officers, and two for non-commiſſioned officers and privates. Their complement is 1072 men, but they will lodge, on emergency, 4 or 500 more.

Town-Houſe.—a fine old building adjoining to the priſon. Only one hall is retained by the body corporate. The remainder contains the Tontine hotel, which was enlarged by ſubſcription upon lives. The coffee-room is, perhaps, the largeſt and fineſt in Europe. It is ſupported by annual ſubſcription, the ſubſcribers amounting to upwards of 1000, who pay one pound five ſhillings each.

Bridges.—Three of theſe are of ſtone, and a fourth was actually built in the year 1795, when the river riſing rapidly, in conſequence of exceſſive rains, it was ſwept away in one night when very nearly finiſhed. The arches being very flat, and the extremities not ſufficiently ſecured, the accident was attributed, by profeſſional perſons, to the lateral preſſure. Its place has ſince been ſupplied by a very handſome wooden bridge for foot paſſengers. The two bridges higheſt upon the river are plain, but very well built and paved. The loweſt, or new bridge, is very finely executed, and is eſteemed one of the moſt compleat ſpecimens of this ſpecies of architecture in Britain.

Water-works.—The city of Glaſgow, until lately, was ſupplied with water by pit-wells, and the water of theſe, although abundant in quantity, was of inferior quality both for waſhing and culinary purpoſes; as, beſides other impurities, it holds in ſolution a conſiderable portion of marine acid, by which it is rendered hard and brackiſh. To remedy this inconvenience a public company was formed, who, at the expence of upwards of 60,000*l*., brought water filtered from the river into every part of the city and ſuburbs by caſt iron pipes, and from theſe pipes into every houſe, upon receiving a moderate annual payment from the proprietor or leſſee. The capital neceſſary was raiſed by transferable ſhares of 50*l*. each. The rapidity with which thoſe ſhares were bought induced others to form a ſeparate eſtabliſhment, and to raiſe water alſo from the river for the ſupply of the city. The firſt ſupply is drawn from the Clyde by two large ſteam engines, into a reſervoir about two miles to the eaſtward of the town. From this reſervoir it is filtered into another, and from thence conveyed by the pipes to a third immediately contiguous to the town. The whole lower part may be ſupplied from this without further forcing, but to ſupply the higher parts, a portion is again forced by another ſmaller engine to a ciſtern on a higher elevation, which commands every part above the former level.

The weſtern water-work company draw their ſupply from the river, to ciſterns ſituated on an eminence about one mile weſt of the town, where it is filtered, and conveyed by pipes, without requiring to be forced a ſecond time. The inhabitants are left to their own free choice from which company to take their ſupply.

River Clyde.—The Clyde takes its riſe about 60 miles to the ſouth-eaſt of Glaſgow, in the ſame mountain which forms the ſources of the Tweed and the Annan. Near the county town of Lanark, about 28 miles above Glaſgow, it has three remarkable falls or cataracts, much viſited by ſtrangers. From Lanark to Glaſgow it paſſes through a fine valley, richly wooded in many places, fertile and highly cultivated. From the new bridge of Glaſgow, where it becomes navigable, until it terminates in St. George's, or the Iriſh channel, about 80 miles diſtant. About thirty years ago, Mr. Goldburn, an eminent engineer, was employed by the city of Glaſgow to deepen the river, from the Broomilau or harbour, to the ſea-port towns of Port Glaſgow and Greenock, the former ſituated 21, and the latter 24 miles below the city. This he effected in a very judicious, although gradual and economical manner. The beneficial effects of his plan became ſoon apparent, have been, every ſucceſſive year, improving, and muſt continue ſo for many years to come. He began by conſtructing, on either bank, projecting dykes, or jetties, into the river, at right angles, to the banks on either ſide, and placed at ſmall diſtances from each other along the whole courſe of the navigation. Theſe jetties intercept much of the earth and gravel waſhed down by ſucceſſive floods, and thus ſupply the materials for ultimate contraction, without the expence of carriage. Beſides this, a number of labourers are employed every ſummer ſeaſon to drag the bottom of the river, and lodge the ſtuff which is withdrawn from the bottom between the projecting jetties. By the conſtant repetition of this ſimple proceſs, a great part of the river is now contracted to leſs than one half of its original breadth, and has gained above four feet of additional depth. As the tonnage dues, the greater part of which is appropriated for this purpoſe, now exceed 6000l. *per annum*, theſe operations promiſe to be continued on a more extended ſcale than ever; and it is probable that in a few years veſſels of large burthen may be brought up to the city. The largeſt hitherto brought up are about 130 tons, the depth of the channel being about nine feet at high water. The gentleman who now directs theſe improvements thinks, that in a few years this depth may be increaſed to 14 feet by the preſent plan.

It was lately propoſed to improve the harbour by the conſtruction of wet docks; but a difference of opinion having ariſen reſpecting the controul under which theſe improvements were to be placed, the ſcheme has been ſuſpended, but it is hoped not finally relinquiſhed. The tonnage dues are one ſhilling *per* ton on merchandiſe, eight-pence on foreign produce, and four-pence on coals, brick, and other building materials. Manure, carried upon the river for the improvement of the adjacent country, is exempted from any tax

The country ſtretching along the banks of the Clyde, for a number of miles, both above and below the city, is generally fertile, and, in moſt places, highly cultivated, and well encloſed. The pariſh of Govan, ſituated on the ſouth bank of the river, is, perhaps, as highly improved as any diſtrict in Britain. Beſides the natural fertility of the ſoil, this may be accounted for by the plentiful ſupply of coal, lime, and manure, which are ſupplied at cheap rates by water-carriage. It muſt alſo be greatly promoted by the circumſtance of there being many landed proprietors, whoſe eſtates, although abundantly ſufficient to maintain themſelves and families in comfort and affluence under their perſonal ſuperintendence, are not ſo large as to induce them to relinquiſh the profits and emoluments of cultivating their own property, which, of courſe, derives the united benefit of their perſonal ſkill, induſtry, and capital, beſides that emulation which a laudable ſpirit of rivalry excites among them to ſurpaſs each other. The higher lands, both to the north and ſouth, are conſiderably inferior, both in ſoil and cultivation, to thoſe in the valley. In every direction round Glaſgow, coal, lime, and iron-ſtone are found in great plenty, and give great advantages to the agricultural and manufacturing claſſes of the community.

The ſuburbs of Glaſgow, which form the chief reſidences of the operative tradeſmen, are the following:

Calton—a very populous village, immediately adjoining to the city on the ſouth-eaſt, and bordering on the *Green* of Glaſgow. This village contains upwards of 20,000 inhabitants, with many manufactories, diſtilleries, &c. The green ſerves both for paſture and for the purpoſes of waſhing and bleaching There are a commodious waſhing-houſe, and fine walks for the recreation of the inhabitants. The dues of waſhing and paſture form part of the city revenue. The green contains upwards of 100 acres of ground.

Bridgetown—another ſuburb adjoining to the former, and ſimilar in every reſpect.

Gorbals—a village on the oppoſite bank of the Clyde, governed by a chief magiſtrate, appointed by the council of Glaſgow, and two reſident baillies.

Anderſton, Brownfield, Finnuſton, and *Partick.*—Theſe four villages lye to the weſt of Glaſgow, on the north bank of the Clyde; they alſo are reſidences for operative tradeſmen, and contain ſeveral extenſive manufactories, *viz.* three large cotton mills, an extenſive puntfield, and porter brewery, at Anderſton; a large and flouriſhing glaſs-work at Finnuſton, and the very large flour-mills belonging to the incorporation of bakers at Glaſgow, at Partick, where are alſo the ruins of an ancient caſtle, formerly belonging to the archbiſhop.

Municipal Government of Glaſgow.

This, as formerly remarked, in ancient times, was almoſt excluſively veſted in the archbiſhop and chapter. Since the reformation, it underwent various changes during the ſucceſſive alterations of government in Scotland at large. The laſt arrangement made by royal and parliamentary authority, was early in the 18th century, under William and Mary. It has ſince been modified by the authority of the Scottiſh convention of royal boroughs, who exerciſe this power without diſpute. As at preſent conſtituted, the government of the city is veſted in the lord provoſt, three merchants, and two trades baillies, the dean of guild, or preſident of the merchants, the convenor, or preſident of the trades, the city treaſurer, and maſter of the public works, twelve counſellors from the merchants, and eleven from the incorporated trades, in all 33 counſellors. To this body the regulation of all the public buſineſs belongs; the lord provoſt being preſident, with the caſting or deciding vote in caſes of parity. The courts of juſtice within the city are the following:

1. The circuit court of juſticiary, for the cognizance of criminal actions, which is held twice a year at Glaſgow, for the counties of Lanark, Renfrew, and Dumbarton, generally before two of the lords commiſſioners, although any one of their number is competent. This court alſo decides appeals in civil cauſes from any of the inferior courts within the diſtrict.

2. The magiſtrates or town court. This court is held under the authority of the magiſtrates, aſſiſted by the town clerks as legal aſſeſſors. The juriſdiction of this court extends to any amount ſubject to an appeal to the court of ſeſſion.

3. The conſcience court, for the deciſion of petty cauſes under twenty ſhillings, where the formality of an oath is diſpenſed with, or any written pleading.

4. The ſitting magiſtrate alſo decides daily trifling claims under five ſhillings. The magiſtrates alſo exerciſe a criminal juriſdiction in petty crimes, and puniſh by impriſonment, pillory, and ſometimes public whipping and baniſhment from the city.

5. The ſheriff court, for the under-ward of Lanarkſhire, is alſo held at Glaſgow, before the ſheriff ſubſtitute. His juriſdiction is equal to that of the magiſtrates, not only within the city, but the diſtrict. The deciſions of this court are ſubject by appeal to the ſheriff depute and to the court of ſeſſion.

6. The juſtice of peace court alſo decides civil cauſes to a limited amount, and regulates diſputes between maſters and ſervants. The appeal from this court is to the quarter ſeſſions, and finally to the court of ſeſſions.

7. The ſmall debt court is held by two or more juſtices, for the deciſion of cauſes under 10*l.* No profeſſional lawyer is heard here, and the pleadings are verbal. They review their own deciſions upon appeal, provided the ſum decerned for be lodged with the clerk of court.

8. The commiſſary court is the remnant of the biſhop's court. It decides for ſums under 3*l.* 6*s.* 8*d.*, and alſo in caſes of defamation. Its juriſdiction extends over all the ancient biſhopric.

Police Eſtabliſhment.—This eſtabliſhment was conſtituted a few years ago under the authority of a ſpecial act of parliament. The commiſſioners named in the act are, the lord provoſt and baillies, and twenty-four commiſſioners elected by twenty-four wards, into which number the city is divided. The qualification of a commiſſioner, is the occupation of a *dwelling* houſe valued at 15*l.* or upwards of yearly rent; and of a voter, that of any houſe at 10*l.* or upwards. The buſineſs of this eſtabliſhment is the lighting, cleaning, and guarding of the ſtreets, and ſuppreſſion of quarrels, riots, and other breaches of the public peace. For this purpoſe a maſter, or intendant of police officers, and watchmen are employed. A magiſtrate ſits every morning at the police office to decide upon thoſe who have been apprehended during the night. Where the charge is ſerious, he generally remits the cognizance of it to the town court, and puniſhes petty delinquencies by a ſmall fine. The expence is defrayed by a tax on the valued rents of ſhops, warehouſes, and dwelling houſes, by fines levied in the courſe of the year by the ſale of manure, from cleaning the ſtreets, &c. The maximum of the tax is from 6*d.* to 1*s.* 3*d.* per pound of valued rent, but much leſs has been generally found ſufficient. This inſtitution has been always hitherto conducted with the moſt vigilant attention to economy, and is very popular even among thoſe of the citizens, who ſtrenuouſly oppoſed its original adoption.

Commerce and Manufactures.—The commercial importance of Glaſgow only began to riſe ſubſequently to the Union, and had attained no very important extent until the colonization of North America opened a wide field for the exportation of Britiſh commodities and the importation of American produce in return. Previous to the commencement of the American war in 1775, it had, however, engaged very extenſively in the tobacco trade, for it appears that of 90,000 hhds. of tobacco imported into Britain in 1772, 49,000 hhds. were brought into the Clyde alone, and, in 1775, the importation was 57,143 hhds.

The operations of the war neceſſarily put a ſtop to this intercourſe, to the great loſs of the merchants engaged in it; many of whom have never been able to recover their debts. Upon the reſtoration of peace in 1783, the trade with America revived, and continued again in a flouriſhing ſtate, until again recently ſuſpended by the American non-intercourſe act. In 1783, the regiſtered veſſels of the Clyde, were 386, and their tonnage 22,896, and in 1803, the number cleared outwards and inwards was as follows.

At Greenock inwards,			
Foreign trade	406 ſhips,	53,546 tons,	5183 men.
Coaſt and fiſhing	730 veſſels,	35,532	3147
Outwards,			
Foreign trade	352 ſhips,	50,366 tons,	3673 men.
Coaſt and fiſhing	1016 veſſels,	43,009	3326
At port Glaſgow inwards,			
Foreign trade	113 ſhips,	18,722 tons,	1081 men.
Coaſt and fiſhing	182 veſſels,	7,226	551
Outwards;			
Foreign trade	177 ſhips,	25,157 tons,	1692 men.
Coaſt and fiſhing	119 veſſels,	7,202	424
Total	3095	238,790	17:077

From this note ſome idea may be formed of the extent of the trade; but many of theſe veſſels having probably made ſeveral voyages in the courſe of the year, it is not to be inferred that this number of veſſels actually belongs or trades to the Clyde. The articles of exportation are chiefly Britiſh manufactured goods, coals, fiſh, &c. and the imports European, American, and colonial produce.

The city of Glaſgow had alſo a very conſiderable commercial intercourſe with the eaſtern parts of the iſland, and with the northern ſtates of Europe, until this was ſuſpended by the events of the war. This intercourſe is carried on by means of the Forth and Clyde canal, which interſects Scotland, and forms a junction between the eaſtern and weſtern ſeas, ſome account of which has already been given under the article CANAL.

The manufactures of Glaſgow had obtained no very great extent previous to the commencement of the American war, although they had been progreſſively advancing during the whole courſe of the eighteenth century. So far back as the reign of Charles II. indeed, ſome attempts had been made to introduce the manufacture of ſoap, refining of ſugar, and ſome other branches, all of which proved abortive, and were diſcontinued. The linen manufacture was the moſt extenſive of the various attempts made, and the moſt ſucceſsful during the time that it laſted. It commenced about the year 1725, and continued progreſſively advancing until it was almoſt entirely ſuperſeded by the cotton towards the cloſe of the century. The cotton manufacture, which is now unqueſtionably the ſtaple trade of Glaſgow, was proſecuted to very ſmall extent until after the year 1784, but when once introduced it advanced with unprecedented rapidity. It is impoſſible to aſcertain with any preciſion its actual amount either in quantity or value at any given period for want of proper data. A computation in 1791 makes the number of looms employed 15,000, and the perſons who earned their ſubſiſtence by various parts of the proceſſes of ſpinning, weaving, bleaching, &c. 135,000. It alſo eſtimates the total value of the goods made yearly at 1,500,000*l*. The grounds of this calculation are not ſtated, and little reliance can be placed on it, for the value of cotton goods has fluctuated as remarkably as the quantity has extended.

Two manufactories of earthen ware are carried on in Glaſgow, but neither of them extenſively. Indeed a much greater quantity of Staffordſhire ware is uſed in the city itſelf than of the produce of either. Two or three rope works are alſo carried on, but to no great extent.

The printing of calicoes and other goods is, however, a very extenſive branch of the manufacture of Glaſgow and its vicinity. The moſt extenſive of theſe works, are thoſe ſituated upon the water of Leven, in Dumbartonſhire, about 18 miles diſtant. The extenſion of the cotton trade has alſo greatly improved and enlarged the number of dye-works, and the manufactures of chemical preparations for the various proceſſes of bleaching, dyeing, and printing. Theſe works are ſituated in the vicinity of the city, chiefly on the banks of the river.

Of the chemical works carried on in Glaſgow, ſome are peculiar to it.

The manufacture of Cudbear was introduced by Mr. Mackintoſh ſo long ago as the year 1777. It is prepared from *rock-moſs*, and above 2000 gallons of human urine are daily conſumed in the proceſs. The cudbear gives a dark reddiſh colour, and is uſed in the dyeing of leather, woollen ſtuffs, &c. The proceſs is kept profoundly ſecret.

The diſcharging of the Turkey red dye is alſo peculiar to Glaſgow. This proceſs is particularly deſcribed under the article *Diſcharging of* COLOUR.

The manufacture of the oxy-muriate of lime, in a dry form, for the purpoſes of bleaching, &c. is alſo almoſt peculiar to Glaſgow. Its object is to decreaſe the expence of bleaching by the ſubſtitution of lime for potaſh. This article is made to great extent by Mr. Tennent the inventor.

Iron liquor, for the uſe of printers, is made here by various perſons, and large alum works are eſtabliſhed in the neighbourhood. Manufactures of red and white lead are alſo carried on.

Miſcellaneous Remarks.

It will appear that the city of Glaſgow has undergone three remarkable changes. Its firſt ſtate was the reſidence of a great archiepiſcopal ſee, and conſequently it was for many ages entirely under clerical influence and controul. Its firſt eminence as a commercial place aroſe from its favourable ſituation for commerce with the American and Weſt Indian colonies, and through this traffick it made rapid advances in commercial importance during the whole courſe of the eighteenth century. One branch of this traffick being at leaſt for the preſent ſuſpended, it now depends chiefly on the other, and upon its manufactures for ſupport. From the facilities of acquiring a good education, the inhabitants of Glaſgow have generally added a conſiderable taſte for literary attainment even to their commercial habits, and this ſtyle prevails, perhaps, in a degree ſuperior to any other commercial place in Britain. The ſyſtem of education is, however, rapidly adapting itſelf to the modern purſuits of the inhabitants, and more pains are now taken to qualify the riſing generation for eminence in the counting-houſe than the cloſet. However deſirable a thorough knowledge of the principles of commercial economy, and the details of buſineſs may be in a commercial community, it is ſtill to be hoped, that all the benefits ariſing from intellectual attainment will not be deemed altogether nugatory, and conſequently neglected. In every ſituation of life, they are ſources of rational and innocent amuſement, and, in the viciſſitudes to which commercial enterpriſe is peculiarly expoſed, may often prove of real benefit and utility to the poſſeſſor.

The city of Glaſgow returns a member to the Britiſh parliament, conjunctly with the neighbouring burghs of Ruthuglen, Renfrew, and Dumbarton.

GLASGOW, *Port*, ſituated on the river Clyde, about 22 miles below the city, is a handſome ſmall town, and was projected by the magiſtrates of Glaſgow at the requeſt of the merchants as a harbour for their ſhips and veſſels. It is ſaid that the firſt plan was to improve the harbour of Dumbarton for this purpoſe, but Dumbarton being a royal borough, the conſent of its magiſtrates became neceſſary, and that when made, it was rejected by that body, who preferred the full enjoyment of their chartered privileges to the idea of ſinking into the mere ſea-port of Glaſgow, however much their wealth, revenue, population, and general proſperity might be benefitted by ſuch an union. If this were the caſe, it is one among the numberleſs inſtances where comfort and proſperity have been ſacrificed to a mere empty title. The harbour of port Glaſgow is good but ſhallow. The diſadvantage of the bank, noticed in the article GREENOCK, is alſo much againſt it as a haven. At port Glaſgow there is a cuſtom-houſe, where the general cuſtoms of the Clyde are collected. There is here alſo a fine graving, or dry dock, built by the merchants of Glaſgow long before that of Greenock was executed, and this circumſtance alone brought many ſhips up to this port which now come no further than Greenock. The ſituation of port Glaſgow is more pleaſant than that of Greenock, the country more level, and better adapted for cultivation. In other reſpects it is certainly

leſs

eſs calculated for the general purpoſes of maritime traffick than its rival, and therefore there is little probability of its extenſion. Indeed the ſhipping belonging to Glaſgow is certainly on the decreaſe, the foreign merchants finding it more for their advantage to freight or charter veſſels for any purpoſe than to build or buy veſſels of their own, which both conſume or ſink a conſiderable portion of their capital, and may, from the many caſualties and fluctuations to which commerce in this eventful age is expoſed, prove rather burthens than advantages, while the mere ſhip-owner, if deprived of a freight or charter-party at one port, may with greater facility ſeek it at another, than the perſon with whom freight is only a ſecondary and inferior conſideration.

Port-Glaſgow is governed by magiſtrates, appointed by the council of Glaſgow, and ſome reſident magiſtrates. Its exports and imports have been already given and compared with thoſe of Greenock under the article Glasgow, which indeed furniſhes by far the greater part of the freight to and from both ports.

There are no manufactures here of any extent, excepting thoſe which are to be found at almoſt all ſea-port towns, *viz.* ſhip building and rope ſpinning. Both of theſe are carried on to a very conſiderable extent. A work was erected ſome years ago for refining of ſugar, and alſo a ſmall cotton-mill, but neither have ever been proſecuted to any great extent.

A plan has been formed, and its execution is now begun, which in time may produce a great effect, both on this town and Greenock. This plan has for its object the formation of a more direct communication between Glaſgow and the weſt ſea, than the preſent circuitous navigation of the Clyde, by means of a navigable canal to be carried from Glaſgow to Ardroſſan, near Irvine, which is about thirty miles farther down the river than the preſent ſeaports. This canal was projected under the ſanction and patronage of the preſent earl of Eglintoun, (lord Ardraſſan of Great Britain,) a part of whoſe eſtates lie in that neighbourhood. Its objects are two-fold. Firſt, to facilitate the maritime intercourſe of Glaſgow and Paiſley with the New World, by a more direct channel and better harbour. Second, to improve the agricultural and internal ſtate of Renfrewſhire, and the northern diſtrict of Ayrſhire, by affording means for the cheap conveyance of coal, lime, manure, and other heavy articles by means of the canal. Ardroſſan is ſituated not more than thirty miles from Glaſgow, by the line of the projected canal, and therefore the carriage of goods will not be more expenſive or tedious than by the Clyde, for the canal being free from the conſtant interruptions ariſing from the operation of wind and tide upon the river, the time of arrival and departure may be depended upon at all ſeaſons and in all weathers. A conſiderable ſum has already been ſubſcribed for the canal, and alſo for the harbour, and from the well-known energy and activity of his lordſhip's general character, there is no reaſon to doubt that every exertion for its ſpeedy completion will be uſed.

It is natural to expect that every oppoſition will be given by thoſe whoſe local intereſts will ſuffer by the ſucceſs of this undertaking, and theſe comprehend many wealthy and powerful claſſes; but whilſt ſome oppoſe, others will find it their intereſt to promote it, and the competition muſt be ultimately advantageous to the general body, however it may terminate as to thoſe more immediately intereſted.

The other part of the plan is the formation of an excellent and ſecure harbour at Ardroſſan, capable of receiving ſhips of large burthen, and this alſo is begun. The ſubſcriptions for the two undertakings are conducted ſeparately. The coaſt here is in ſome places reckoned dangerous during the prevalence of ſtrong gales from the north-weſt, when veſſels are making the land; but it is ſaid that the bay of Lamlaſh, in Arran, will afford a ſafe and eaſy ſhelter within a few hours ſail, when this may prove to be the caſe. The ſurveys, plans, and eſtimates for the canal and harbour of Ardroſſan were made under the ſuperintendance of Mr. Telford. It muſt be perfectly evident that this canal will in all events produce much benefit as it paſſes through the moſt populous and flouriſhing manufacturing diſtrict in Renfrewſhire.

Glasgow, a new county of America, in Newbern diſtrict, North Carolina, taken from Dobbs's county: bounded N. by Edgcomb, S. by Lenoir, E. by Pitt, and W. by Wayne.—Alſo, a town of New York, on the E. coaſt of lake Cayuga; eight miles S. of Cayuga.

GLASS, in the general acceptation of this term among *Chemiſts*, denotes any ſubſtance or mixture, earthy, ſaline, or metallic, which is reduced by igneous fuſion to the ſhape of a hard, brittle, uniform maſs, which breaks with a conchoidal fracture, paſſing into ſplintery, and with a high degree of luſtre. Moſt glaſſes of this kind are alſo tranſparent. See Vitrification.

Glass, *Vitrum*, in a more reſtricted ſenſe, and as the term is commonly uſed in the *arts* and *manufactures*, ſignifies that tranſparent, ſolid, brittle, factitious ſubſtance, produced by the vitrification of ſiliceous earth with various ſalts and metallic oxyds, which is applicable to innumerable purpoſes of ornament and comfort, as well as of ſcientific inveſtigation and reſearch.

As to the antiquity of the term *glaſs*, Tacitus (Germ. c. 45.) and Pliny (l. xxxvii. c. 3.) inform us, that amber was called among the ancient Gauls or Germans by the name of *gleſum* or *gleſſum*; and from the ſimilarity which glaſs bore to amber with reſpect to tranſparency and brightneſs, it acquired a name, which was, in all probability, originally the ſame. The word *gleſum* denoted, without doubt, a ſhining or tranſparent ſubſtance, as *gleiſſen* expreſſes at preſent in the German language to ſhine; and our Engliſh word to *gliſten* is derived from it, and has nearly the ſame ſignification. Ducange ſays that ſome critics were of opinion, that the word *gleſum* itſelf implied glaſs rather than amber. The ancient Greeks, as it has been obſerved, applied the ſame term (ηλεκτρον) both to glaſs and amber. The herb with which the Britons painted their bodies had alſo the name of *glaſtum*, perhaps from the ſhining appearance it might give to their ſkins, or poſſibly becauſe its aſhes might be uſed in the making of glaſs. The Latins called the ſame plant by the name of *vitrum*, the word they uſed to ſignify glaſs. (Cæſar. Bell. Gall. l. v.)

We find frequent mention of this plant in ancient writers, particularly Cæſar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with glaſtum, guadum, vitrum, &c. *i. e.* with the blue colour procured from this plant. And hence, as ſome have ſuppoſed, the factitious matter we are ſpeaking of, came to be called glaſs, as having always ſomewhat of this bluiſhneſs in it.

Merret (Not. in Ant. Neri de Art. Vitrar.) gives us the following characters or properties of glaſs, by which it is diſtinguiſhed from all other bodies, *viz.* 1. That it is an artificial concrete of ſalt and ſand, or ſtones. 2. Fuſible by a ſtrong fire. 3. When fuſed, tenacious and coherent. 4. It does not waſte or conſume in the fire. 5. When melted, it cleaves to iron. 6. Ductile, when red-hot, and faſhionable into any form, but not malleable; and capable of being blown into a hollowneſs, which no mineral is. (See Ductility *of Glaſs*.) 7. Frangible when thin, without annealing. 8. Friable when cold. 9. Always diaphanous, whether hot or cold. 10. Flexible and elaſtic. 11. Diſſoluble by cold and moiſture. 12. Only capable of being graven, or cut with a diamond or other hard ſtones, and emery. 13. Receives any colour or dye, both externally and internally. 14. Not diſſolvable by aquafortis, aqua-regia, or mercury. 15. Neither acid juices, nor any other matter, extract either colour, taſte, or any other quality, from it. 16. It admits of poliſhing. 17. Neither loſes of weight nor ſubſtance, by the longeſt and moſt frequent uſe. 18. Gives fuſion to other metals, and ſoftens them. 19. The moſt pliable thing in the world, and that which beſt retains the faſhion given it. 20. Not capable of being calcined. 21. An open glaſs, filled with water in the ſummer-time, will gather drops of water on the outſide; juſt ſo far as the water on the inſide reaches; and a man's breath blown upon it will manifeſtly moiſten it. 22. Little glaſs balls, filled with water, mercury, and other liquor, and thrown into the fire, as alſo drops of green glaſs broken, fly aſunder, with a loud noiſe. 23. Neither wine, beer, nor any other liquor, will make it muſty, nor change its colour, nor ruſt it. 24. It may be cemented as ſtones and metals. 25. A drinking-glaſs, partly filled with water, and rubbed on the brim with a wet finger, yields muſical notes, higher or lower, as the glaſs is more or leſs full; and this makes the liquor friſk and leap. See ARMONICA. For the electrical properties of glaſs, ſee ELECTRIC, &c.

GLASS, *origin and hiſtory of*. De Neri will have glaſs as ancient as Job; for that writer, chap. xxviii. ver. 17. ſpeaking of wiſdom, ſays, "gold and glaſs cannot equal it."

This, we are to obſerve, is the reading of the Septuagint, Vulgate Latin, St. Jerom, Pineda, &c. for in the Engliſh verſion, inſtead of glaſs, we read *cryſtal;* and the ſame is done in the Chaldee, Arias Montanus, and the king of Spain's edition. In other verſions, &c. it is read *ſtone;* in others *beryl:* in the Italian, Spaniſh, French, High and Low Dutch, &c. *diamond;* in others, *carbuncle;* and in the Targum, *looking-glaſs*.

In effect, the original word is *zechuchith*, (זכוכית) which is derived from the root *zacac, to purify, cleanſe, ſhine, be white, tranſparent:* and the ſame word (Exod. xxx. 34.) is applied to frankincenſe; and rendered in the Septuagint *pellucid*. Hence the reaſon of ſo many different renderings; for the word ſignifying *beautiful* and *tranſparent*, in the general, the tranſlators were at liberty to apply it to whatever was valuable and tranſparent.

Herodotus (l. iii.) is, according to Dr. Falconer (Mancheſter Memoirs, vol. ii.), the moſt ancient writer (B. C. 440) who uſed the word 'υαλος, which is generally underſtood to ſignify glaſs. But he evidently does not mean artificial glaſs, nor cryſtal, but, moſt probably, ſomewhat of the talcky kind, or lapis ſpecularis, which might readily be framed in ſuch a manner, as to form a convenient tranſparent caſe, ſuch as the ancient hiſtorian has deſcribed. Ariſtophanes (B. C. 400) ſeems to be the next writer who mentions glaſs: that poet, in his comedy called the Clouds, ſcene I. act. 2. uſes the word *hyalus*, υαλος, which is now ordinarily rendered glaſs. He there introduces Strepſiades teaching Socrates a new way to pay old debts, *viz.* "by placing a fair tranſparent ſtone, ſold by the druggiſts, from which the fire is ſtruck, between the ſun and the writing, and ſo melting away the letters thereof." This ſtone Socrates calls υαλος, which the Scholiaſt on Ariſtophanes derives from ὕειν, *to rain*, from the likeneſs it bears to ice, which is rain, or water congealed; though, it muſt be owned, the word υαλος is ambiguous, and ſignifies *cryſtal* as well as *glaſs:* and Gorræus obſerves, that the ancients had a kind of yellow amber, tranſparent as glaſs, called by ſome υαλος.

Ariſtotle (B. C. 340) has two problems upon glaſs: the firſt, Why we ſee through it? The ſecond, Why it is not malleable? If theſe problems be Ariſtotle's, which the learned doubt very much, this would properly be the earlieſt teſtimony in favour of the antiquity of glaſs. Theophraſtus (B. C. 303) ſeems to have been well acquainted with glaſs; for he deſcribes it as having been made of the ſand of the river Belus, which was called υαλι-, to which he adds, that the commoneſt kinds are made with copper. The celebrated ſphere of Archimedes (B. C. 209), if it be truly deſcribed, is a remarkable inſtance of the perfection to which the art of making glaſs had been brought at that early period.

Lucian mentions large drinking glaſſes; and Plutarch, in his Sympoſiacon, ſays, that the fire of tamariſk wood is the fitteſt for making of glaſs.

Among the Latin writers, Lucretius is the firſt that takes notice of glaſs; "Niſi recta foramina tranant, qualia ſunt vitri;" lib. vi. v. 3. Dr. Merret, however, adds, that glaſs could not be unknown to the ancients, but that it muſt needs be as ancient as pottery itſelf, or the art of making bricks; for ſcarcely can a kiln of bricks be burnt, or a batch of pottery-ware be made, but ſome of the bricks and ware will be at leaſt ſuperficially turned to glaſs.

Hence, Ferrant. Imperatus, lib. xxv. cap. 7. "Glaſs, like the common kind, is found under ground, in places where great fires have been. Other glaſſes are found in round clods, like fire-ſtone, ſome brittle, others firm, &c. This foſſil glaſs is wrought by the Americans, and uſed inſtead of iron. And no doubt but vitrifications were more common in the ancient bricks than they are in ours; as they tempered their earth two years together, and burnt them better.

Virgil (B. C. 39) compares the clearneſs of the water of the Fucine lake to glaſs. Æneid, v. 759. Horace (B. C. 36) is more expreſs, and mentions glaſs in terms that ſhew its clearneſs and brightneſs to have been brought to great perfection. Carm. iii. Od. 2. Od. 13. In the time of Strabo, (A. D. 27) the manufacture of glaſs was undoubtedly well underſtood, and had become a conſiderable article. Seneca (A. D. 65) was not only well acquainted with glaſs as a ſubſtance, but alſo underſtood its magnifying powers when formed into a convex ſhape. Quæſt. Natur. lib. iii. vi.

Pliny (A. D. 77) relates the manner of the diſcovery of glaſs. It was firſt made of ſand, according to that author, (Nat. Hiſt. l. xxxvi. c. 66, &c.) found in the river Belus, a ſmall river of Galilee, running from the foot of mount Carmel, out of the lake Cendevia. The part of the ſhore where the ſand was dug did not exceed 500 paces in extent, and had been uſed many ages before for the ſame purpoſe. The report of its diſcovery was, that a merchant ſhip, laden with nitre, or foſſil alkali, being driven upon the coaſt, and the crew going aſhore for proviſions, and dreſſing their victuals upon the ſhore, made uſe of ſome pieces of foſſil alkali to ſupport their kettles. By theſe means a vitrification of the ſand beneath the fire was produced, which afforded a hint for the manufacture. In proceſs of time the calx of iron, in form of the magnetical ſtone, came to be uſed along with the foſſil alkali, from an idea of its not only containing iron, but glaſs, in a liquid form. Clear pebbles, ſhells, and foſſil ſand, were alſo in many places employed for the ſame purpoſe. It is ſaid, that in India pieces of native cryſtal were uſed for that purpoſe; and on that account the Indian glaſs was preferred to any other. Pliny adds, that light and dry woods were uſed for the melting of glaſs; to which they added copper from the iſland of Cyprus, and the foſſil alkali, eſpecially that which is brought from the Eaſt Indies. The furnaces are kept burning without intermiſſion, that the copper may be melted with the glaſs, and out of this compound are made maſſes of a coarſe blackiſh colour. Theſe lumps or maſſes are again melted, and tinged of the colour required. Some of theſe pieces are brought to the ſhape required by blowing with the breath; ſome are ground on a lathe, and others are emboſſed in the ſame manner as ſilver. Sidon was formerly famous for theſe manufactures, as ſpecula or looking-glaſſes were firſt invented there; "ſiquidem etiam ſpecula excogitaverat." Such is the ancient method of making glaſs, deſcribed by Pliny. In his time, it was made with ſand found at the mouth of the river Vulturnus, upon the ſhore, for ſix miles between Cumæ and the Lucrine bay. This ſand was very fine, and was ground to powder with a ball or ſphere and a mill. It was then mixed with three parts of the foſſil alkali, either by weight or meaſure; and being fuſed, was conveyed in a liquid ſtate into other furnaces, where it was formed into a maſs, called "ammonitrum," (or ſand combined with the foſſil alkali,) which maſs was melted, and became then pure glaſs, and a maſs of white vitrified matter. The ſame method of making it prevailed in Spain and Gaul. Glaſs was likewiſe made to imitate the lapis Obſidianus, a ſubſtance found by a perſon of the name of Obſidius, in Egypt and Ethiopia. This ſubſtance was of a very black colour, yet obſcurely tranſparent, and often placed among ſpecula in the walls of rooms, to reflect the ſhadow of objects. It was alſo uſed for the ſame purpoſe as gems (probably for engraving upon) and even for ſtatues. Pliny mentions, that he ſaw ſolid ſtatues of the emperor Auguſtus made of this material; and the ſame emperor dedicated four elephants made of the ſame ſubſtance in the temple of Concord. It ſeems to have been uſed from great antiquity; but in the time of Pliny the artificial imitation of it by glaſs was uſed inſtead of the native material; and he intimates that the black colour was produced by ſome colouring ingredient. The Romans had likewiſe an opaque red kind of glaſs, uſed for plates and diſhes for the table, called "hæmatinon," one of various colours, called "myrrhinum," a white, a clear red, a blue, and indeed moſt other colours. Pliny obſerves, that no ſubſtance was more manageable in receiving colours, or being formed into ſhape, than glaſs. The perfectly clear glaſs, which bore the greateſt reſemblance to cryſtal, was, however, moſt valued. Nero gave for two cups, with two handles to each, and of no extraordinary ſize, 6000 ſeſtertia, or nearly 50,000*l.* ſterling. The inferior kinds were not uncommon, as Pliny informs us, that the uſe of glaſs cups had nearly ſuperſeded thoſe of gold and ſilver. We ſhall here add, that Pliny knew the power of a hollow glaſs globe, filled with water, in concentrating the rays of light, ſo as to produce flame in any combuſtible ſubſtance upon which the focus fell; and he alſo mentions, that ſome ſurgeons in his time made uſe of it as a cauſtic for ulcers (l. xxxvii. c. 2.). He was likewiſe acquainted with the comparative hardneſs of gems and glaſs, as he obſerves, that the lapis Obſidianus would not ſcratch the true gems; and he alſo mentions (l. xxxvii. c. 13.), the counterfeiting of the latter, in his time, as a very lucrative art, and brought to great perfection. He alſo ſays, that glaſs might be cut or engraven upon by means of diamonds, which art is evidenced by the antique gems ſo frequently found. (See Gem.) Joſephus, (l. ii. c. 10.) mentions the ſand of the river Belus, in Galilee, as fit for making glaſs.

The firſt time we hear of glaſs made among the Romans was in the reign of Tiberius, when Pliny relates that an artiſt had his houſe demoliſhed for making glaſs malleable, or rather flexible; though Petronius Arbiter, and ſome others, aſſure us, that the emperor ordered the artiſt to be beheaded for his invention. In the time of Martial, (A.D. 84) glaſs was not only brought to great perfection, and in common uſe for drinking veſſels, but was employed (as it ſeems) for bottles in which wine was kept, and likewiſe for pots to hold flowers. (Epig. 1. l. ii. 22. 40. l. iv. 86.) Galen (A.D. 143) frequently mentions glaſs in ſeveral parts of his works, and ſeems to have been well acquainted with the method of making it. Apuleius (A.D. 161) mentions the manufacture of glaſs cups, in his time, as highly wrought and carved in various ways, and of great value. Alexander Aphrodiſienſis (A.D. 214) a Greek writer, and a commentator on Ariſtotle, has ſeveral remarks on glaſs reſpecting both its brittleneſs, eſpecially on change of temperature, and its tranſparency.

The manufacturers of glaſs formed a company at Rome, and had a ſtreet aſſigned them, in the firſt region of the city, near the Porta Capena. A tax was laid upon them by Alexander Severus (A.D. 220) which ſubſiſted in the time of Aurelian, and probably long after.

Mr. Nixon, in his obſervations on a plate of glaſs found at Herculaneum, which was deſtroyed A. D. 80, on which occaſion Pliny loſt his life, offers ſeveral probable conjectures as to the uſes to which ſuch plates might be applied.

Such plates, he ſuppoſes, might ſerve for *ſpecula*, or looking-glaſſes; for Pliny, in ſpeaking of Sidon, adds, "ſiquidem etiam ſpecula excogitaverat;" the reflection of images from theſe ancient ſpecula being effected by beſmearing them behind, or tinging them through with ſome dark colour. (See Mirror.) Another uſe in which they might be employed, was for adorning the walls of their apartments by way of wainſcot, to which Pliny is ſuppoſed to refer by his *vitreæ cameræ* (lib. xxxvii. cap. 25. § 64.). Mr. Nixon farther conjectures, that theſe glaſs plates might be uſed for windows, as well as the laminæ of lapis ſpecularis and phengites, which were improvements in luxury mentioned by Seneca, and introduced in his time, Ep. xc. However, there is no poſitive authority relating to the uſage of glaſs windows earlier than the cloſe of the third century: "Manifeſtius eſt," ſays Lactantius, "mentem eſſe, per oculos ea quæ ſunt oppoſita, tranſpiciat, quaſi per feneſtras lucente vitro aut ſpeculari lapide obductas." De Opificio Dei, cap. 5. See Phil. Tranſ. vol. l. art. 80. p. 601. vol. lii. art. 23. p. 123.

St. Jerome (A. D. 422) ſpeaks of windows formed of glaſs, melted and caſt into thin plates, as being uſed in his time. Paulus Silentiarius, a poet and hiſtorian of the 6th century (about A.D. 534), ſpeaks of the brightneſs of the ſun's rays, paſſing through the eaſtern windows of the church of St. Sophia, at Conſtantinople, which windows were covered with glaſs. Gregory of Tours (A. D. 571) laments the devaſtations frequently committed on the windows of the churches by the ravages of war. Johannes Philoponus, who lived about the year 630, or, as ſome ſay, a century earlier, not only ſpeaks of glaſs, but of the panes being faſtened in with plaſter, much in the ſame way as at preſent.

If the opinion of Pennant, ſuggeſted under the article Anguinum *ovum*, be well founded, we have reaſon to believe, that, long before the conqueſt of Britain by the Romans, the art of manufacturing glaſs into ſuch ornaments as beads and amulets was known among the Druids; and if the art was thus applied, it is not improbable to ſuppoſe, that it was employed for more important and uſeful purpoſes, as in the manufacture of glaſs veſſels. Nor is it likely that the Britons derived this art from the Romans, who preferred ſilver and gold to glaſs for the compoſition of their drinking veſſels. Beſides, the glaſs that was commonly uſed by the Romans was of an inferior quality, and appears from ſome remains of it diſcovered at their ſtations and houſes to have conſiſted of a thick, ſometimes white, but moſtly blue-green, metal.

According to venerable Bede, artificers ſkilled in making glaſs were brought over into England, in the year 674, by abbot Benedict, who were employed in glazing the church and monaſtery of Weremouth. According to others, they were firſt brought over by Wilfrid, or Wigfrid, biſhop of Worceſter, about the ſame time, or, as others think, at a later period, A. D 726. Till this time the art of making glaſs, or at leaſt of applying it to this purpoſe, was unknown in Britain: though glaſs windows did not begin to be uſed before the year 1180: till this period they were very ſcarce in private houſes, and conſidered as a kind of luxury, and as marks of great magnificence. Italy had them firſt, next France, from whence they came into England.

Leo Oſtienſis (A. D. 760) ſpeaks of the windows in his time being made with glaſs-plates fixed in lead, and faſtened together with iron. Anaſtaſius, an hiſtorian of Rome, who was librarian to the pope, mentions, that in the pontificate of Leo III. who became pope about the year 800, painted glaſs in windows was in uſe. The ſtatutes of the church of Traguier, in Lower Britany, about the year 1156, ſpeak of the windows of churches and chapels being ornamented with arms and military enſigns, painted upon the glaſs in them. A charter of Richard II. of England, quoted by Rymer, (A. D. 1386), contains a paragraph in which is mentioned glaſs, together with the manufacture of it for windows.

Venice, for many years, excelled all Europe in the fineneſs of its glaſſes; and in the thirteenth century, the Venetians were the only people who had the ſecret of making cryſtal looking-glaſſes, and which they performed by blowing, much in the ſame manner as a conſiderable quantity of the common mirror-glaſs is now manufactured. The great glaſs-works were at Muran, or Murano, a village near the city, which furniſhed all Europe with the fineſt and largeſt glaſſes.

The glaſs manufacture was firſt begun in England in 1557: the finer ſort was made in the place called Crutched Friars, in London; the fine flint glaſs, little inferior to that of Venice, was firſt made in the Savoy-houſe, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with ſea-coal or pit-coal, inſtead of wood, and a monopoly was granted to ſir Robert Manſell, who was allowed to import the fine Venetian flint glaſſes for drinking, the art of making which was not brought to perfection before the reign of William III. But the firſt glaſs plates, for looking-glaſſes and coach windows, were made in 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced the manufacture of fine glaſs into England, by means of Venetian artiſts, with amazing ſucceſs. So that within a century paſt, the French and Engliſh have not only come up to, but even ſurpaſſed, the Venetians, and we are now no longer ſupplied from abroad.

The French made a conſiderable improvement in the art of glaſs, by the invention of a method to caſt very large plates, till then unknown, and ſcarce practiſed yet by any but themſelves and the Engliſh. That court applied itſelf with a laudable induſtry to cultivate and improve the glaſs manufacture. A company of glaſs-men was eſtabliſhed by letters patent; and it was provided by an arret, not only that the working in glaſs ſhould not derogate any thing from nobility, but even that none but nobles ſhould be allowed to work therein.

It was in the year 1665, under the miniſtry of the great Colbert, that a company for "blown-mirror-glaſs" was firſt eſtabliſhed near Cherbourg, in Normandy, on the plan of the Venetian manufacture; but the beautiful art of caſting glaſs was invented in France about the year 1688, by a perſon of the name of Abraham Thevart; and a company was ſoon eſtabliſhed for this branch of manufacture, which was firſt carried on at Paris, and ſoon after removed to St. Gobin, where it ſtill exiſts in full activity, and undiminiſhed reputation. An extenſive manufactory of this kind was firſt eſtabliſhed among us near Preſcot in Lancaſhire, about the year 1773, by a reſpectable body of proprietors, who were incorporated by an act of parliament. They ſtruggled for a conſiderable time with difficulties; but being nobly relieved and encouraged by government, they have ſucceeded in producing plates rivalling, if not ſurpaſſing in ſize, quality, or brilliancy, the moſt celebrated continental manufactures. This company furniſhes, at Albion Place, London, plates of various dimenſions, from 12 to 144 inches in length, and from 10 to 72 inches in breadth; and alſo convex and concave mirrors, from 12 to 36 inches in diameter.

GLASS, *Ingredients of.* The materials uſed in the compoſition are ſome ſaline ſubſtance and ſome ſort of ſiliceous earth.

1. The firſt ingredient we ſhall ſpecify is ſilex or flint. The beſt is that which will melt, and which is white and tranſparent. It is this that gives conſiſtence and firmneſs to the glaſs. This is found principally in Italy, being a ſort of ſtony ſubſtance called *tarſo*: the next is *puocoli*, or *cuogola*, a ſort of pebbles found at the bottoms of rivers, and gathered for the Venetian manufacture out of the river Po, which are ſaid not to be inferior in whiteneſs to alabaſter.

Indeed, nothing makes finer and clearer glaſs than common flint, diſtinguiſhed for this uſe by its clear tranſparent, black colour; this, before it is uſed, muſt be heated red-hot, and then immediately quenched in cold water. The heat whitens it, and the water cauſes it to ſplit in every direction, and facilitates the grinding of it. The charge of preparing this deters the glaſs-men from uſing it. The rounded fragments of quartz, found in the beds of rivers among mountains, are ſometimes uſed in foreign countries, being firſt heated and ground to powder. Indeed, the preparation neceſſary for ſtone, in general, is to calcine, powder, and ſearce it.

Ant. Neri obſerves, that all white tranſparent ſtones, which will not burn to lime, are fit to make glaſs; and that all ſtones which will ſtrike fire with ſteel, are capable of being employed in making of glaſs. But this latter rule, Dr. Merret obſerves, does not hold univerſally. Where proper ſtone cannot be had, ſand is uſed; and it is now almoſt the only kind of ſubſtance employed in the Britiſh manufactures of glaſs. The beſt for this purpoſe is that which is white, ſmall, and ſhining: examined by the microſcope, it appears to be ſmall fragments of rock cryſtal. For green glaſs, that which is of a ſoft texture, and more gritty; it is to be well waſhed, which is all the preparation it needs. Our glaſs-houſes are furniſhed with white ſand for their cryſtal glaſſes from Lynn in Norfolk, and Maidſtone in Kent, and from the weſtern extremity of the Iſle of Wight; and with the coarſer, for green glaſs, from Woolwich.

2. The ſecond ingredient in the manufacture of glaſs is an alkali, which is either ſoda, or pot-aſh. It is always uſed at firſt in the ſtate of carbonat, though the carbonic acid flies off in the proceſs. For the method of preparing each, ſee CARBONAT. Theſe alkalies are uſed in different degrees of purity according to the required quality of the glaſs. The fineſt ſort of glaſs requires the beſt pearl-aſhes, purified by ſolution and evaporation, to dryneſs; but for inferior glaſſes coarſer alkalies, ſuch as barilla,

wood-aſhes, and kelp, are employed. The aſhes of fern will alſo yield a ſalt, which will make excellent glaſs; and, moreover, the aſhes of the cods and ſtalks of beans, as alſo thoſe of coleworts, bramble buſh, millet-ſtalks, ruſhes, cyperuſes, and many other plants, may be uſed for the like purpoſe, and after the ſame manner.

There are other fluxes uſed for different kinds of glaſs, and for various purpoſes. Lime, in the form of chalk, is employed in the manufacture of glaſs; but this muſt be uſed only in ſmall proportions; for an exceſs would act powerfully on the ſides of the glaſs-pots, in conſequence of the eſcape of the carbonic acid from the chalk during the fuſion, and, beſides, it would render the glaſs opaque and milky in cooling, however clear it might be when hot. It is known by experience, that to 100 parts of ſilex and the requiſite quantity of alkali, no more than about ſix or ſeven parts of quick-lime, or chalk, can be added, without affecting the clearneſs of the glaſs. Borax is another very valuable flux; but its high price reſtricts the uſe of it to the fineſt kinds of glaſs, and to thoſe which are required to be free from ſpecks and bubbles. A very ſmall quantity of borax will correct any deficiency of ſtrength in the alkali.

Of the oxyds of lead, litharge and minium are found to be of ſingular uſe in the manufacture of glaſs. Litharge is a powerful flux, and imparts to glaſs the valuable qualities of greater denſity and greater power of refracting the rays of light, and of bearing ſudden changes from heat to cold, without being ſo liable to crack, and alſo greater tenacity when red-hot, ſo that it is more eaſily wrought. A conſiderable quantity of this oxyd is contained in the finer glaſſes; ſuch as the London flint glaſs, and that which is uſed for the table, for luſtres, for artificial gems, and for moſt optical purpoſes. Glaſs, however, that contains much lead, is extremely ſoft; and liable to be injured by hard bodies that come into contact with it; and it is alſo very fuſible. It is alſo liable to be corroded by very acrid liquors. Beſides, the uſe of lead renders it difficult ſo to unite the ſilex and alkali, that a piece of glaſs ſhall be throughout of uniform denſity. Another ingredient occaſionally uſed in glaſs is the black oxyd of manganeſe, called "glaſs-ſoap," from its uſe in clearing the glaſs from any accidental foulneſs of colour, and more eſpecially from the green tinge, owing to the preſence of iron. Scheele and Bergman in their reſpective "Eſſays," have illuſtrated many curious circumſtances that attend the uſe of manganeſe in glaſſes, which are particularly detailed in Aikin's Dictionary. The manganeſe ſhould be choſen of a deep colour, and free from ſpecks, of a metalline appearance, or a lighter caſt: and it requires to be well calcined in a hot furnace, and then to undergo a thorough levigation. The effect of manganeſe in deſtroying the colours of glaſs is accounted for by M. Montamy, in his "Traité des Couleurs pour la Peinture en Email," in the following manner; the manganeſe deſtroys the green, olive, and blue colours of glaſs, by adding to them a purple tinge, and by the mixture producing a blackiſh brown colour; and as blackneſs is cauſed merely by an abſorption of the rays of light, the blackiſh tinge given to the glaſs by the mixture of colours, prevents the reflection of ſo many rays, and thus renders the glaſs leſs coloured than before. But the black produced by this ſubſtance ſuggeſts an obvious reaſon for uſing it very ſparingly in thoſe compoſitions of glaſs, which are required to be very tranſparent.

This purple colour may be corrected by charcoal, or in the glaſs-houſe, by thruſting a billet of wood down into the melted glaſs, which becomes charred by the intenſe heat, and cauſes the purple hue to vaniſh, with a ſlight efferveſcence of the glaſs, and eſcape of numerous ſmall air-bubbles. On the other hand, if a ſmall quantity of nitre is added to glaſs containing manganeſe, the purple colour is reſtored, or, if preſent, the diſcolouring effect of the charcoal is prevented, till the nitre becomes alkalized by the heat, and mixes with the other ingredients of the crucible. For the explanation of theſe phenomena, it is obſerved, that the oxyd of manganeſe gives the purple colour only ſo long as it remains in its higher ſtate of oxygenation; but when in contact with charcoal, the latter partially deoxygenates it, carbonic acid gas is formed, the cauſe of the bubbles obſerved on this occaſion, and the colour is now loſt. Nitre, on the other hand, is known to give out oxygen largely as ſoon as red-hot; and hence the manganeſe immediately retakes from this ſource the oxygen of which the charcoal had deprived it, and reſumes its colouring power. The other ſubſtances which take away the colour from glaſs, tinged red with manganeſe, are all the ſalts with the baſis of ſulphuric acid, ſuch as gypſum, ſulphat of ſoda, &c. and alſo ſulphur itſelf; likewiſe the oxyds of tin and iron, and of ſome other metals. Nevertheleſs theſe ſubſtances have this power only when in contact with charcoal. The tinging power of manganeſe is perfectly deſtroyed by the addition of arſenic in any form. Thus, a mixture of oxyd of cobalt and oxyd of manganeſe, in the colouring ſtate, is of a dark purple; but on the addition of any arſeniat, or of white arſenic, the manganeſe is made inactive, and the proper cobalt-blue alone appears. Hence we perceive the neceſſity, when the red colour of manganeſe is wanted, to avoid any thing arſenical; and nitre is alſo generally added to keep the manganeſe always at the proper ſtate for imparting its colour. The oxyd of manganeſe is a very powerful flux for all earthy matters; and this, as well as lead, gives a great denſity to glaſs. The white oxyd of arſenic is another powerful and cheap flux in the making of glaſs; but it ſhould be very moderately uſed; for it takes a longer time to mix intimately with glaſs, and to allow it to be perfectly clear, than any other of the additions commonly employed. For want of this the glaſs has a milky hue, which increaſes with age; and when the arſenic is in exceſs, the glaſs becomes gradually ſoft, and is decompoſed. Beſides, glaſs of this kind is unſafe to be uſed in the form of drinking veſſels.

Nitre is alſo uſed, in ſmall quantities, in the manufacture of glaſs, and is deſigned to anſwer particular purpoſes, ſome of which we have already ſpecified. It not only ſerves to deſtroy the ſtrong tinge of yellow which is found in glaſs, prepared with lead as a flux; but in ſaline glaſs, it is requiſite, in a ſmaller proportion, to render it ſufficiently tranſparent, as in the caſe of looking-glaſſes, and other kinds of plates. For an account of Mr. Dollond's excellent contrivance for deſtroying the colours in the object-glaſſes of teleſcopes, &c. ſee ABERRATION.

With regard to the ſeveral fluxes above enumerated, we may obſerve, in general, that the more calx of lead, or other metallic earth, enters into the compoſition of any glaſs, ſo much the more fuſible, ſoft, coloured, and denſe this glaſs is, and reciprocally.

The colours given to glaſs by calces of lead are ſhades of yellow: on the other hand, glaſſes that contain only ſaline fluxes partake of the properties of ſalts; they are leſs heavy, leſs denſe, harder, whiter, more brilliant, and more brittle than the former; and glaſſes, containing both ſaline and metallic fluxes, do alſo partake of the properties of both theſe ſubſtances. Glaſſes too ſaline are eaſily ſuſceptible of alteration by the action of air and water; eſpecially thoſe in which alkalies prevail; and theſe are alſo liable to be injured by acids. Thoſe that contain too much borax and arſenic, though at firſt they appear very beautiful, quickly tarniſh, and become opaque when expoſed to air. By attending to theſe properties of different fluxes, phlogiſtic or ſaline, the artiſt may know how to adjuſt the proportions of theſe to ſand, or powdered flints, for the various kinds of glaſs.

Glass, *proportion of ingredients in.* Different kinds of glaſs require different proportions; nor have theſe been preciſely aſcertained. We ſhall here, and in ſubſequent articles, ſtate ſeveral of the moſt uſual and approved mixtures that have been propoſed. When ſilex is melted with twice its weight, or more, of dry carbonated alkali, either potaſh or ſoda, the reſult is a very ſoft deliqueſcent vitreous maſs, always more or leſs opaque, ſtrongly alkaline to the taſte, and which, on expoſure to moiſt air, or more ſpeedily in water, totally diſſolves into a clear liquor, which is a ſolution of ſilex in alkali. When the ſame alkali is equal to the ſilex in weight, or does not much exceed it, the glaſs is now tranſparent, but it is ſtill ſoluble in water. It is not till the alkali is diminiſhed to about one-half of the weight of the ſilex, that the glaſs becomes perfectly hard and inſoluble in any corroſive liquors, (the fluoric acid excepted,) and, in ſhort, acquires the character of a perfect glaſs. This proportion, therefore, of two parts of ſand to one of alkali, is uſually the datum on which the doſes of the alkalies actually uſed are regulated. Thus, if common wood aſhes (of which the alkaline part is reckoned at no more than 10 per cent.) are employed, 100lbs. of theſe would require no more than about 20lbs. of ſand. If the beſt Spaniſh barilla, containing from 45 to 50 per cent. of carbonate of ſoda, be uſed, an equal weight of ſand may be added; but if purified pearlaſh be taken, it will melt down perfectly twice its own weight of ſand. But glaſſes compoſed merely of pure alkali and ſand, require a very ſtrong fire for their fuſion, and are hard, harſh, and difficult to break: they are therefore never uſed alone. As one half the weight of the ſand is reckoned an abundant allowance of alkali, it follows of courſe that when litharge, arſenic, borax, or any other fluxes are employed, the quantity of alkali will be proportionally diminiſhed. The following proportions are extracted from Macquer's Chemical Dictionary. If a glaſs be required that is denſe, fuſible, and not ſaline, one part and a half of red lead or litharge may be mixed with one part of ſand, and fuſed together: if equal parts of ſand and of calx of lead be employed, a glaſs ſomewhat leſs denſe and harder will be produced: if a glaſs be required of very little denſity, only ſaline fluxes muſt be employed. A glaſs of this kind may be compoſed of ſix parts of ſalt of tartar, or of potaſh, or of purified ſoda, mixed with eight parts of ſand or of flints; or of four parts of any of the above-mentioned alkalies, mixed with two parts of nitre or of borax, and eight parts of vitrifiable earth. When a cryſtal glaſs is required, which ſhall be of an intermediate quality betwixt the metallic and ſaline glaſſes, it may be made from a mixture of one part of the above mentioned ſalts, one part of calx of lead, and two parts of ſand or other vitrifiable earth. By varying the proportion of theſe ingredients, many different kinds of glaſſes may be produced, each of which may be good, if the quantity of each of the fluxes employed be proportionable to its vitrifying power.

Glass, *inſtruments for manufacturing.* Theſe are ſubſervient to two different purpoſes; *viz.* the levigation and mixture of the ingredients, and the fuſion or vitrification of them. To the former claſs belong horſe or hand-mills, mortars and peſtles, flat ſtones and mullars, and ſearces or ſieves. The other ſort of utenſils are furnaces, with the proper iron work, pots for containing the compoſition when put into the fire, and iron inſtruments for ſhifting the matter out of one into the other, in caſe of accidents; and for taking out ſmall portions, in order to judge of the progreſs of the vitrification, and the qualities of the glaſs, &c. See the following articles. See alſo Glass-*houſe*, Furnace, and Glass-*pots*.

Glass, *fuſion of.* When the ingredients are ſelected and duly proportioned, they are firſt calcined for a longer or ſhorter time, before they are put into the glaſs-pots. This operation is called "fritting," and is performed either in ſmall furnaces adjoining to the proper glaſs-furnace, and heated by the ſame fuel after its chief force has been ſpent upon the glaſs-pots, or elſe in ſmall furnaces or ovens conſtructed for this purpoſe. The uſes of fritting are, to expel all moiſture from the ingredients, by which the glaſs-pots would be endangered; to diſcharge part of the carbonic acid from the alkalies and chalk. and thus to moderate the ſwelling in the glaſs-pots, and eſpecially to cauſe an adheſion, or commencement of chemical union, between the alkali and ſilex, and metallic oxyds. This operation ſhould be performed gradually, and carried to the point of ſemi-vitrification, in which the materials ſtrongly adhere, and begin to become paſty, but are ſtill opaque and not homogeneous. This operation ſerves alſo to deſtroy any carbonaceous matter. When the ingredients are ſufficiently fritted, they are thrown with clean iron ſhovels through the ſide-opening of the furnace into the glaſs-pots, the fire having been previouſly raiſed to its greateſt intenſity, to prevent the furnace from being chilled and to ſave time. The pots are charged by two or three ſucceſſive portions, the preceding one being thoroughly melted down before another portion is thrown in. When filled, the ſide-opening is cloſed up with wet clay, excepting a ſmall hole for examining the work, which cloſure is pulled down when the glaſs is well refined and about to be worked off. As ſoon as the frit begins to feel the action of the fire in the glaſs-pots, which is immediately raiſed to its greateſt pitch, it ſinks down into a ſoft paſty ſtate, increaſing in tenacity till the fuſion is complete. However, it is ſtill opaque, from the riſing of a white porous ſcum, known by the name of "ſandiver," or "glaſs-gall." This ſubſtance appears to be a confuſed maſs, conſiſting of all thoſe ſalts contained in common alkalies, which readily melt at ſomewhat leſs than a glaſs-melting heat, and are either naturally ſoluble in a conſiderable degree, or have little, if any, affinity for ſilex, and not uniting in the compoſition of glaſs, but being lighter, riſe to the top. Another heterogeneous ſubſtance, called "ſandiver," is ſometimes found at the bottom of the pots. This is quite different from the other, and ſeems to conſiſt of a vitrified maſs of arſenic and other impurities. But the ſcum, or proper "glaſs-gall," is almoſt entirely ſaline. When laded out and cooled, it forms a crumbly maſs, ſometimes white, at other times brown and fouled, and ſtrongly ſaline, but not uniform in its compoſition, being ſometimes merely ſalt, often very bitter, probably as common ſalt or ſulphat of potaſh predominates. It is ſo volatile in a ſtrong fire, that it is conſtantly diſperſing from the ſurface of the glaſs in a denſe vapour, which is firſt thick and black, afterwards whiter, and which corrodes the top of the crucible in its paſſage. With long continued fuſion it would entirely eſcape in this ſtate, if it were not ſcummed off with long ladles, and ſold to metal refiners as a powerful flux. Abundance of this glaſs-gall is attended with one of the greateſt inconveniences to the maker of glaſs, as it requires a conſiderable continuance of ſtrong heat to diſſipate the whole of it, or otherwiſe the glaſs would be full of bubbles, unſound, and having a cloudy gelatinous appearance. It is obſerved, that glaſs from potaſh is more likely to ſuffer from glaſs-gall than the ſoda-glaſs is, becauſe the potaſh glaſſes are harder, and do not run ſo thin as the other, and the glaſs-gall from them does not ſo eaſily diſſipate in the fire.

During this proceſs ſamples for examination are drawn out of the pots with an iron rod; and the glaſs gradually becomes more and more flexible, denſe, and leſs brittle, and at laſt the glaſs-gall is entirely diſſipated. Whilſt the heat is continued, the glaſs which was full of ſpecks and bubbles is refined, and becomes beautifully clear, tranſparent, and colourleſs; and this proceſs, which goes on from the ceſſation of the vapour of the glaſs-gall and its entire removal to the time when the glaſs is altogether clear and free from bubbles, is called the "refining." After this the glaſs is complete; but being too thin for working, it is cooled, by ſtopping the draught of fire round the pot which contains it, and in cooling it thickens to a fit ſtate for being wrought. For glaſs that is caſt into plates, leſs cooling is neceſſary, as it is required to flow very thin and hot. On an average it takes about 48 hours for the fine flint glaſſes, from the time when the pots are firſt filled till the glaſs is ready for working, in which ſtate it is of a very full red colour, and poſſeſſes a ſingular kind of conſiſtence and tenacity. It is juſt ſoft enough to yield with eaſe to any external impreſſion, even to the force of the breath urged pretty ſtrongly in the centre of the glowing maſs, and may be bent and ſhaped in every poſſible way; and ſuch is its tenacity, that it extends uniformly without any cracks or fiſſures; but when ſtretched out to the utmoſt, it forms a ſolid ſtring, the diameter of which is conſtantly decreaſing till it ſeparates from the maſs in a thin capillary thread. It ſtiffens as it cools, and becomes perfectly brittle and alſo tranſparent. As melted glaſs adheres very feebly to poliſhed metal, it is very eaſily wrought with bright iron tools.

GLASS, *working or blowing round.*—Every kind of glaſs, plate-glaſs excepted, is formed from a hollow globe that has been produced by blowing. For this purpoſe the operator takes his blowing-iron, which is a hollow tube, about four or five feet long, and dipping it in the melting-pot, turns it about there till the metal adheres to the iron like ſome glutinous or clammy juice; he then holds it near the ground, ſo that the maſs is extended by its own weight, and blows ſtrongly into the tube. With his breath thus penetrating into the centre of the red-hot maſs, he enlarges it into an uniform hollow globe of the requiſite thickneſs and bulk, keeping the force of his breath upon it for a few ſeconds till it ſtiffens by cooling, and thus preventing its ſinking by the compreſſion of the denſer external air. This globe, adhering by a neck to the iron rod, is formed by the dexterity of the workman, and by a variety of ingenious manœuvres into all the common utenſils. As a ſpecimen of his art, we may inſtance a common tumbler. The hollow globe already mentioned is taken off the iron rod by the following ſimple proceſs: An aſſiſtant dips the end of a ſhort ſolid iron rod into the glaſs-pot, and, bringing out at its extremity ſome of the melted glaſs, thruſts it immediately againſt the hollow of the globe at the part directly oppoſite to the neck, to which it firmly unites, and thus the globe is cemented by the melted glaſs to the ſecond rod. The workman then wets a ſmall piece of iron with his mouth, and lays it on the neck of the globe, which is extremely hot, and this, in a ſecond or two, cracks it round; ſo that with a ſlight pull it comes off and detaches the hollow rod, leaving the globe open at the neck, and transferred to the ſecond rod at the oppoſite ſide. The open globe is again ſoftened by holding it a few ſeconds over the mouth of the glaſs-pot, and is cut away from the open end to the form of a cup by iron ſhears. The operator, when employed in faſhioning the globe, uſually ſits upon a kind of arm-chair, with its arms ſloping forwards and covered with a flat ſmooth iron-plate; and by laying the iron rod ſtraight before him, reſting on both the arms of his ſeat, and twirling it backwards and forwards, the hot glaſs at the end is made to revolve like clay on a potter's lathe, and thus is opened, widened, or compreſſed at pleaſure by any ſimple iron inſtrument that is preſſed againſt it. The globular cup is thus extended eaſily into a cylinder, or made into the ſhape of a barrel, if this form be required, and is ſmoothed up at the edges. In order to ſeparate it from the iron-rod, it is wetted as before at the point of attachment, and the tumbler drops off complete. This laſt operation leaves that burr or roughneſs, with ſharp fragments, which is ſeen at the bottom of all glaſs-veſſels, unleſs it be taken off by poliſhing. The next operation is that of cooling the veſſel very gradually, called "annealing." See *Annealing of* GLASS.

GLASS, *different kinds of.* The manufactured glaſs now in uſe may be divided into three general kinds; white tranſparent glaſs, coloured glaſs, and common green or bottle-glaſs. Of the firſt kind, there is a great variety; as the flint glaſs, as it is called with us, and the German cryſtal glaſs, which are applied to the ſame uſes; the glaſs for plates for mirrors or looking-glaſſes; the glaſs for windows and other lights; and the glaſs for phials and ſmall veſſels. And theſe again differ in the ſubſtances employed as fluxes in forming them, as well as in the coarſeneſs or fineneſs of ſuch as are uſed for their body. The flint and cryſtal, mirror, and beſt window glaſs, not only require ſuch purity in their fluxes, as may render it practicable to free the glaſs perfectly from all colour: but for the ſame reaſon likewiſe, either the white Lynn ſand, calcined flints, or white pebbles, ſhould be uſed. The others do not demand the ſame nicety in the choice of the materials; though the ſecond kind of window glaſs, and the beſt kind of phial, will not be ſo clear as they ought, if either too brown ſand, or impure ſalts, be ſuffered to enter into their compoſition.

Of coloured glaſs there is a great variety of ſorts, differing in their colour, or other properties, according to the occaſions for which they are wanted. The differences in the latter kind depend on the accidental preparation and management of the artiſts by whom they are manufactured.

GLASS, *Cryſtal.* Foreigners uſe this term for our flint glaſs, and for making it they give the following directions: Take of the whiteſt tarſo, pounded ſmall, and ſearced as fine as flour, two hundred pounds; of the ſalt of polverine, a hundred and thirty pounds: mix them together, and put them into the furnace, called the *calcar*, firſt heating it. For an hour keep a moderate fire, and keep ſtirring the materials with a proper rake, that they may incorporate and calcine together; then increaſe the fire for five hours; after which take out the matter; which, being now ſufficiently calcined, is called frit. From the calcar put the frit in a dry place, and cover it up from the duſt for three or four months.

Now, to make the glaſs, or cryſtal: Take of this cryſtal frit, called alſo *bollito;* ſet it in pots in the furnace, adding to it a due quantity of manganeſe: when the two are fuſed, caſt the fluor into fair water, to clear it of the ſalt, called *ſandiver;* which would otherwiſe make the cryſtal obſcure and cloudy. This lotion muſt be repeated again and again, as often as needful, till the cryſtal be fully purged; or, this ſcum may be taken off by means of proper ladles. Then ſet it to boil four, five, or ſix days; which done, ſee whether it have manganeſe enough; and if it be yet greeniſh, add more manganeſe, at diſcretion, by little and little at a time, taking care not to overdoſe it, becauſe the manganeſe inclines it to a blackiſh hue. Then let the metal clarify, till it becomes of a clear and ſhining colour; which done, it is fit to be blown, or formed into veſſels at pleaſure.

Glass, *Flint*, as it is called in our country, is of the ſame general kind with that which in other places is called cryſtal glaſs. It has this name from being originally made with calcined flints, before the uſe of the white ſand was underſtood; and retains the name though no flints are now uſed in the compoſition of it. This flint glaſs differs from the other, in having lead for its flux, and white ſand for its body; whereas the fluxes uſed for the cryſtal glaſs are ſalts or arſenic, and the body conſiſts of calcined flints, or white river pebbles, tarſo, or ſuch ſtones. This glaſs, on account of the quantity of litharge, which enters into its compoſition, is the heavieſt, the moſt brilliant, the ſofteſt and moſt eaſy to work, and alſo the moſt expenſive. It is that fine glaſs, of which the common and moſt valuable articles of white glaſs in domeſtic or ornamental uſe are manufactured; and beſides, many optical inſtruments are made of this ſubſtance. To the white ſand and lead a proper proportion of nitre is added, for the purpoſes ſpecified in a former part of this general article, and alſo a ſmall quantity of manganeſe, and in ſome works they uſe a proportionable quantity of arſenic to aid the fluxing ingredients. The moſt perfect kind of flint glaſs may be made by fuſing with a very ſtrong fire a hundred and twenty pounds of the white ſand, fifty pounds of red lead, forty pounds of the beſt pearl-aſhes, twenty pounds of nitre, and five ounces of manganeſe.

From others we have the following compoſition for glaſs of this kind, ſaid to be of the beſt quality, *viz.* 120 parts of fine clear white ſand, 40 of pearl-aſhes well purified, 35 of litharge or minium, 13 of nitre, and a ſmall quantity of black oxyd of manganeſe.

The following compoſition for a fine cryſtal glaſs is given by Loyſel; 100 pounds of white ſand, 80 to 85 of red oxyd of lead, 35 to 40 of pearl-aſh, 2 to 3 of nitre, and one ounce of manganeſe. The ſpecific gravity of this glaſs, and of the common London flint-glaſs, is about 3.2.

Another compoſition of flint glaſs, which is ſaid to come nearer to the kind now made, is the following: a hundred and twenty pounds of ſand, fifty-four pounds of the beſt pearl-aſhes, thirty-ſix pounds of red lead, twelve pounds of nitre, and ſix ounces of manganeſe. To either of theſe a pound or two of arſenic may be added, to increaſe the flux of the compoſition. A cheaper compoſition of flint glaſs may be made with a hundred and twenty pounds of white ſand, thirty-five pounds of the beſt pearl-aſhes, forty-pounds of red-lead, thirteen pounds of nitre, ſix pounds of arſenic, and four ounces of manganeſe; or, inſtead of the arſenic, may be ſubſtituted fifteen pounds of common ſalt; but this will be more brittle than the other. The cheapeſt compoſition for the worſt kind of flint-glaſs, conſiſts of a hundred and twenty pounds of white ſand, thirty pounds of red-lead, twenty pounds of the beſt pearl-aſhes, ten pounds of nitre, fifteen pounds of common ſalt, and ſix pounds of arſenic. The beſt German cryſtal glaſs is made of a hundred and twenty pounds of calcined flints, or white ſand, ſeventy pounds of the beſt pearl-aſhes, ten pounds of ſalt-petre, half a pound of arſenic, and five ounces of manganeſe. And a cheaper compoſition is formed of a hundred and twenty pounds of calcined flints, or white ſand, forty-ſix pounds of pearl-aſhes, ſeven pounds of nitre, ſix pounds of arſenic, and five ounces of manganeſe.

A glaſs, much harder than any prepared in the common way, may be made by means of borax in the following method: take four ounces of borax, and an ounce of fine ſand; reduce both to a ſubtile powder, and melt them together in a large cloſe crucible ſet in a wind-furnace, keeping up a ſtrong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glaſs, capable of cutting common glaſs like a diamond. This experiment, duly varied, may lead to ſeveral uſeful improvements in the arts of glaſs, enamels, and factitious gems, and ſhews an expeditious method of making glaſs, without any fixed alkali, which has been generally thought an eſſential ingredient in glaſs; and it is not yet known whether calcined cryſtal, or other ſubſtances, being added to this ſalt inſtead of ſand, it might not make a glaſs approaching to the nature of a diamond. Shaw's Lectures, p. 426.

Glass, *Crown*, is the beſt ſort of window-glaſs, and differs from the flint-glaſs in containing no lead, nor any metallic oxyd, except manganeſe, and ſometimes oxyd of cobalt, in minute doſes, not as a flux, but for correcting the natural colour. This glaſs is much harder and harſher to the touch than the flint-glaſs; but when well made it is a very beautiful article. It is compounded of ſand, alkali, either potaſh or ſoda, the vegetable aſhes that contain the alkali, and generally a ſmall portion of lime. A ſmall doſe of arſenic is often added to facilitate the fuſion. Zaffre, or the oxyd of cobalt, with ground flint, is often uſed to correct the dingy yellow of the inferior ſort of crown-glaſs, and by adding the blue, natural to glaſs coloured with this oxyd, to convert the whole into a ſoft light green. One ounce of zaffre is ſufficient for 1000lbs. But when the ſand, alkali, and lime are very fine, and no other ingredients are uſed, no zaffre nor corrective of bad colour is required. A very fine glaſs of this kind may be made by 200 parts of pretty good ſoda, 300 of fine ſand, 33 of lime, and from 250 to 300 of the ground fragments of glaſs. We had formerly in London two kinds of crown glaſs, diſtinguiſhed by the places where they were wrought; *viz.* 1. *Ratcliff crown glaſs*, which is the beſt and cleareſt, and was firſt made at the Bear-garden, on the Bank-ſide Southwark, but ſince at Ratcliff: of this there are twenty-four tables to the caſe, the tables being of a circular form, about three feet ſix inches in diameter.

2. *Lambeth crown glaſs*, which is of a darker colour than the former, and more inclining to green. The following compoſition has been recommended for the beſt window or crown glaſs, *viz.* white ſand, ſixty pounds; of purified pearl-aſhes, thirty pounds; of ſalt-petre, fifteen pounds; of borax, one pound; and of arſenic, half a pound. If the glaſs ſhould prove yellow, manganeſe muſt be added. A cheaper compoſition for window glaſs conſiſts of ſixty pounds of white ſand, twenty-five pounds of unpurified pearl-aſhes, ten pounds of common ſalt, five pounds of nitre, two pounds of arſenic, and one ounce and a half of manganeſe. The common, or green window glaſs, is compoſed of ſixty pounds of white ſand, thirty pounds of unpurified pearl-aſhes, ten pounds of common ſalt, two pounds of arſenic, and two ounces of manganeſe. But a cheaper compoſition for this purpoſe, conſiſts of a hundred and twenty pounds of the cheapeſt white ſand, thirty pounds of unpurified pearl-aſhes, ſixty pounds of wood-aſhes well burnt and ſifted, twenty pounds of common ſalt, and five pounds of arſenic.

The manufacture of the common window glaſs, though made by blowing, is conducted differently from that of the flint glaſs articles; as it is the object to produce a large, flat, very thin plate of glaſs, which is afterwards cut by the glazier's diamond into the requiſite ſhape. Without minutely detailing the ſeveral gradations of the proceſs, it may be here mentioned, that the workman takes a very large maſs of melted glaſs on his hollow iron rod, and by rolling it on an iron plate and ſwinging it backwards and forwards, cauſes it to lengthen, by its own weight, into a cylinder, which is made hollow and brought to the required thinneſs, by blowing with a fan of breath, which perſons accuſtomed to the buſineſs know how to command. The hollow cylinder is then opened by holding it to the fire, which, by expanding the air confined within it, (the hole of the iron rod being ſtopped,) burſts it at the weakeſt part, and when ſtill ſoft, it is ripped up through its whole length by iron ſhears, opened out into a flat plate, and finiſhed by annealing as uſual.

The large crown glaſs of Meſſrs. Hammond and Smith is ſuperior in quality as well as in ſize to that of any other manufacture. The uſual diameter of the tables in other manufactures may be taken at 47 or 48 inches, with an occaſional variation in a table of one or two inches: and the largeſt ſquare which can be cut from theſe meaſures about 24 inches by 20, and in ſome circumſtances one inch wider or longer. Whereas the glaſs of Meſſrs. Hammond and Smith is 60 inches in diameter, and will admit of being cut into ſquares of about 33 inches by 23 inches; and a little more or leſs. This glaſs is almoſt free from thoſe ſpecks, wreaths, &c. which diſcolour other glaſs, and diſtort the objects ſeen through it. It now ſupplies the place of German ſheet glaſs for prints, large ſaſhes, and exportation to thoſe foreign markets where that glaſs was formerly in uſe.

Glass, *French*, as alſo called *Normandy glaſs*, and formerly *Lorraine glaſs*, becauſe it was made in thoſe provinces: though it has ſince been made wholly in the nine glaſs works; five of which were in the foreſt of Lyons, four in the country of Eu; the laſt at Beaumont, near Rouen. It is of a thinner kind than our crown claſs; and, when laid on a piece of white paper, appears of a dirtyiſh-green colour. There are but twenty-five tables of this to the caſe.

Glass, *German*, is of two kinds, the *white* and the *green*: the firſt is of a whitiſh colour, but is ſubject to thoſe ſmall curved ſtreaks, obſerved in our Newcaſtle glaſs, though free from the ſpots and blemiſhes thereof. The green, beſides its colour, is liable to the ſame ſtreaks as the white; but both of them are ſtraighter, and leſs warped, than our Newcaſtle glaſs.

Glass, *Dutch*, is not much unlike our Newcaſtle glaſs, either in colour or price. It is frequently much warped, like that, and the tables are but ſmall.

Glass, *Newcaſtle*, is that moſt uſed in England. It is of an aſh-colour, and much ſubject to ſpecks, ſtreaks, and other blemiſhes; and, beſides, is frequently warped. Leybourn ſays, there are forty-five tables to the caſe, each containing five ſuperficial feet: ſome ſay there are but thirty-five tables, and ſix feet in each table.

Glass, *Phial*, is a kind of glaſs betwixt the flint glaſs and the common bottle, or green glaſs. The beſt kind may be prepared with a hundred and twenty pounds of white ſand, fifty pounds of unpurified pearl-aſhes, ten pounds of common ſalt, five pounds of arſenic, and five ounces of mangeneſe. The compoſition for green or common phial glaſs, conſiſts of a hundred and twenty pounds of the cheapeſt white ſand, eighty pounds of wood aſhes, well burnt and ſifted, twenty pounds of pearl-aſhes, fifteen pounds of common ſalt, and one pound of arſenic.

Glass, *common green bottle*, is made almoſt entirely of ſand, lime, and ſometimes clay, alkaline aſhes of any kind, as cheapneſs or convenience direct, and more eſpecially of kelp in this country, of barilla, varec, and the other varieties of ſoda in France, and of wood aſhes in many parts of Germany, and the like. To theſe ingredients is ſometimes added the earth remaining from ſaline aſhes, after the alkali and ſalts have been extracted by lixiviation, and in England flags from the iron furnaces. Bottle-glaſs is a very hard well-vitrified glaſs, which reſiſts the corroſive action of all liquids much better than flint glaſs. It is uſed, not only for wine-bottles, but for very large retorts, ſubliming veſſels, and other articles of the chemical apparatus; and it has for this purpoſe the advantage of bearing as much as a pretty full red heat without melting or ſinking down into a ſhapeleſs lump, as the lead-glaſſes would do. The following compoſition is given by Loyſel as a good and cheap material for bottle-glaſs; *viz.* 100 parts of common ſand, 30 of varec (a kind of coarſe kelp made on the weſtern coaſts of France), 160 of the lixiviated earth of aſhes, 30 of freſh wood-aſh, or any other kind of aſh, 80 of brick-clay, and any quantity, generally about 100, of broken glaſs. This compoſition yields no glaſs-gall. This kind of glaſs is formed of ſand of any kind, fluxed by the aſhes of burnt wood, or of any parts of vegetables; to which may be added the ſcoriæ or clinkers of forges. When the ſofteſt ſand is uſed, two hundred pounds of wood-aſhes will ſuffice for a hundred pounds of ſand, which are to be ground and mixed together. The compoſition with the clinkers conſiſts of a hundred and ſeventy pounds of wood-aſhes, a hundred pounds of ſand, and fifty pounds of clinkers, or ſcoriæ, which are to be ground and mixed together. If the clinkers cannot be ground, they muſt be broke into ſmall pieces, and mixed with the other matter without any grinding.

A good bottle-glaſs, but nearly black and opaque, has been made in France of the decompoſed pulverulent baſaltic earth found in the vallies of all baſaltic countries. In France it abounds in the Vivarais, in Languedoc, and Auvergne. The firſt glaſs of this kind appears to have been made in 1780 by a M. Ducros at the ſuggeſtion of Chaptal, who ſimply melted ſome of this baſalt without addition in a glaſs-pot, and formed of it two very light, black, or rather deep yellow, ſhining, perfect bottles. In ſubſequent trials by another artiſt, a mixture of equal parts of baſalt and ſand was employed, as preferable to the baſalt alone; but notwithſtanding a conſiderable demand for bottles of this material, the manufacture was abandoned for want of uniformity in the ingredients, which made them often fail. The colour of this glaſs was of a green-olive.

The green colour, tranſmitted by bottle-glaſs, when in its perfect ſtate, is owing to the iron contained both in the vegetable aſhes and in the ſea-ſand, which enter into its compoſition. This glaſs affords an inſtance of a ſemi-pellucid ſubſtance, which exhibits a blue colour by incident light, and a yellow or orange colour by that which is tranſmitted. See Delaval on the cauſe of the permanent colour of opaque bodies.

Glass, *Plate*, is the moſt perfect and beautiful glaſs, of which all the kinds of mirrors and looking-glaſſes are compoſed. The materials of which this kind of glaſs is made are much the ſame as thoſe of other works of glaſs, *viz.* an alkali ſalt, and ſand.

To prepare the ſalt, they clean it well of all foreign matters; pound or grind it with a kind of mill, and finally ſift it pretty fine.

Pearl-aſhes, properly purified, will furniſh the alkali ſalt requiſite for this purpoſe; but it will be neceſſary to add borax, or common ſalt, in order to facilitate the fuſion, and prevent the glaſs from ſtiffening in that degree of heat, in which it is to be wrought into plates. For purifying the pearl-aſhes, diſſolve them in four times their weight of boiling water, in a pot of caſt iron, always kept clean from ruſt. Let the ſolution be removed into a clean tub, and remain there twenty-four hours, or longer. Having decanted the clear part of the fluid from the dregs or ſediment, put it again in the iron pot, and evaporate the water till the ſalts are left perfectly dry. Preſerve them in ſtone jars, well ſecured from air and moiſture.

Pearl-aſhes may alſo be purified in the higheſt degree, ſo as to be proper for the manufacture of the moſt tranſparent glaſs, by pulverizing three pounds of the beſt pearl-aſhes, with ſix ounces of ſalt-petre, in a glaſs or marble mortar, till they are well mixed; and then putting part of the mixture into a large crucible, and expoſing it in a furnace to a ſtrong heat. When this is red-hot, throw in the reſt gradually; and when the whole is red-hot, pour it out on a moiſtened ſtone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire till the ſalts be entirely melted; let it then ſtand to cool, and filter it through paper in a pewter cullender. When it is filtered, put the fluid again into the pot, and evaporate the ſalt to dryneſs, which will then be as white as ſnow; the nitre having burnt all the phlogiſtic matter that remained in the pearl-aſhes, after their former calcination.

As to the ſand, it is to be ſifted and waſhed, till ſuch time as the water come off very clear; and when it is well dried again, they mix it with the ſalt, paſſing the mixture through another ſieve. This done, they lay them in the annealing furnace for about two hours; in w[illegible] the matter becomes very light and white: in this ſtat[illegible]re called *frit*, or *fritta*; and are to be laid [illegible] a dry clean place, to give them time to incorporate. They lie here for at leaſt a year.

When they would employ this frit, they lay it for ſome hours in the furnace, adding to ſome the fragments or ſhards of old and ill made glaſſes; taking care firſt to calcine the ſhards by heating them red-hot in the furnace, and thus caſting them into cold water. To the mixture muſt likewiſe be added manganeſe, to promote the fuſion and purification.

The beſt compoſition for looking-glaſs plates is ſaid to conſiſt of ſixty pounds of white ſand cleanſed, twenty-five pounds of purified pearl-aſhes, fifteen pounds of ſalt-petre, and ſeven pounds of borax. If a yellow tinge ſhould affect the glaſs, a ſmall proportion of manganeſe, mixed with an equal quantity of arſenic, ſhould be added. An ounce of the manganeſe may be firſt tried; and if this proves inſufficient, the quantity ſhould be increaſed.

A cheaper compoſition for looking-glaſs plate conſiſts of ſixty pounds of the white ſand, twenty pounds of pearl-aſhes, ten pounds of common ſalt, ſeven pounds of nitre, two pounds of arſenic, and one pound of borax.

The materials of the fineſt plate glaſs, ſuch as that of French manufacture, are white ſand, ſoda, and lime, to which are added manganeſe and zaffre, or any other oxyd of cobalt for particular colouring purpoſes. The ſand is of the fineſt and whiteſt kind, which ſhould be previouſly paſſed through a wire ſieve, moderately cloſe, into water, in which it ſhould be well ſtirred about and waſhed. The ſharpeſt grained ſand is preferred, and it is found that grains of moderate ſize melt with the alkali ſooner, than the very fine duſt or the larger fragments. The alkali is always ſoda, which is preferable to potaſh, as glaſſes made with ſoda are found to be ſofter and to flow thinner when hot, and yet to be equally durable when cold. Beſides, the neutral ſalts with the baſis of ſoda which conſtitute the glaſs-gall in this inſtance, ſuch as the muriat and ſulphat of ſoda, appear to be diſſipated more readily by the fire than the correſponding ſalts of potaſh. The ſoda that is uſed is conſiderably pure, or ſuch as is ſeparated from the rough aſhes of barilla, and other ſoda plants by lixiviation. Lime adds to the fuſibility of the other materials, ſupplying the uſe of litharge in the flint-glaſs; but exceſs of it would impair the colour and ſolidity of the glaſs. About 1-15th of the whole is as much as can properly be uſed; but ſome reduce the quantity to 1-24th. The decolouring ſubſtances are azure, or cobalt blue, and manganeſe. Beſides theſe, there is always a great quantity of the fragments of glaſs, collected from the waſte of the manufacture, which are made friable by quenching in water when hot, and uſed in this ſtate together with the freſh materials. As to the quantities and proportions of the ingredients, much latitude is allowed. The following are ſaid to produce a very fine glaſs; *viz.* 300lbs. of ſand; 200lbs. of ſoda; 30lbs. of lime; 32 ounces of manganeſe; three ounces of azure; and 300lbs. of fragments of glaſs. In the manufactory at St. Gobin ſecrecy is obſerved with regard to the materials; but it is affirmed, and with much probability, that borax is uſed in ſmall quantity.

Of the materials now enumerated the ſand, ſoda, lime, and manganeſe are firſt mixed together with more care than for ordinary glaſs, and they are fritted in ſmall furnaces built for this purpoſe, the heat being gradually raiſed to a full red-white, and then kept with frequent ſtirring till the materials undergo no farther change, nor yield any kind of vapour. The azure and glaſs fragments being already in a ſtate of perfect vitrification are not added till juſt at the end of the proceſs, which laſts about ſix hours. When the materials are thus prepared, they are fit for plate-glaſs, to be formed either by blowing or caſting. The largeſt glaſſes at St. Gobin are run; the middle-ſized and ſmall ones are blown.

Blowing looking-glaſs plates. The work-houſes, furnaces, &c. uſed in the making of this kind of plate-glaſs, are the ſame, except that they are ſmaller, and that the carquaiſſes are diſpoſed in a large covered gallery, over-againſt the furnace, as thoſe in the following article, to which the reader is referred.

After the materials are vitrified by the heat of the fire, and the glaſs is ſufficiently refined, the workman dips in his blowing iron, ſix feet long, and two inches in diameter, ſharpened at the end, which is put in the mouth, and widened at the other, that the matter may adhere to it. By this means he takes up a ſmall ball of matter, which ſticks to the end of the tube by conſtantly turning it. He then blows into the tube, that the air may ſwell the annexed ball: and carrying it over a bucket of water, which is placed on a ſupport at the height of about four feet, he ſprinkles the end of the tube to which the matter adheres, with water, ſtill turning it, that by this cooling, the matter may coaleſce with the tube, and be fit for ſuſtaining a greater weight. He dips the tube again into the ſame pot, and proceeds as before; and, dipping it in the pot a third time, he takes it out, loaded with matter, in the ſhape of a pear, about ten inches in diameter, and a foot long, and cools it at the bucket; at the ſame time blowing into the tube, and, with the aſſiſtance of a labourer, giving it a balancing motion, he cauſes the matter to lengthen; which, by repeating this operation ſeveral times, aſſumes the form of a cylinder, terminating like a ball at the bottom, and in a point at the top. The aſſiſtant is then placed on a ſtool three feet and a half high; and on this ſtool there are two upright pieces of timber, with a croſs beam of the ſame, for ſupporting the glaſs and tube, which are kept in an oblique poſition by the aſſiſtant, that the maſter workman may with a puncheon ſet in a wooden handle, and with a mallet make a hole in the maſs: this hole is drilled at the centre of the ball that terminates the cylinder, and is about an inch in diameter. When the glaſs is pierced, the defects of it are perceived; if it is tolerably perfect, the workman lays the tube horizontally on a little iron treſſel, placed on the ſupport of the aperture of the furnace. Having expoſed it to the heat for about half a quarter of an hour, he takes it away, and with a pair of long and broad ſhears, extremely ſharp at the end, widens the glaſs, by inſinuating the ſhears into the hole made with the puncheon, whilſt the aſſiſtant, mounted on the ſtool, turns it round, till, at laſt, the opening is ſo large as to make a perfect cylinder at bottom. When this is done, the workman lays his glaſs upon the treſſel, at the mouth of the furnace, to heat it: he then gives it to his aſſiſtant on the ſtool, and with large ſhears cuts the maſs of matter up to half its height. There is at the mouth of the furnace an iron tool, called *pontil*, which is now heating, that it may unite and coaleſce with the glaſs juſt cut, and perform the office which the tube did before it was ſeparated from the glaſs. This pontil is a piece of iron, ſix feet long, and in the form of a cane or tube, having at the end of it a ſmall iron bar, a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the glaſs, about four inches thick. This red-hot pontil is preſented to the diameter of the glaſs, which coaleſces immediately with the matter round the pontil, ſo as to ſupport the glaſs for the following operation. When this is done, they ſeparate the tube from the glaſs, by ſtriking a few blows with a chiſſel upon the end of the tube, which has been cooled; ſo that the glaſs breaks directly, and makes this ſeparation, the tube being diſcharged of the glaſs now adhering to the pontil. They next preſent to the furnace the pontil of the glaſs, laying it on the treſſel to heat, and redden the end of that glaſs, that the workman may open it with his ſhears, as he has already opened one end of it, to complete the cylinder; the aſſiſtant holding it on his ſtool as before. For the laſt time, they put the pontil on the treſſel, that the glaſs may become red-hot, and the workman cuts it quite open with his ſhears, right overagainſt the fore-mentioned cut; this he does as before, taking care that both cuts are in the ſame line. In the mean time, the man who looks after the carquaiſſes, comes to receive the glaſs upon an iron ſhovel, two feet and a half long without the handle, and two feet wide, with a ſmall border of an inch and a half to the right and left, and towards the handle of the ſhovel. Upon this the glaſs is laid, flattening it a little with a ſmall ſtick a foot and a half long, ſo that the cut of the glaſs is turned upwards. They ſeparate the glaſs from the pontil, by ſtriking a few gentle blows between the two with a chiſſel. The glaſs is then removed to the mouth of the hot carquaiſſe, where it becomes red-hot gradually; the workman, with an iron tool, ſix feet long, and widened at the end in form of a club at cards, four inches long, and two inches wide on each ſide, very flat, and not half an inch thick, gradually lifts up the cut part of the glaſs, to unfold it out of its form of a flattened cylinder, and render it ſmooth, by turning it down upon the hearth of the carquaiſſe. The tool, already deſcribed, being inſinuated within the cylinder, performs this operation, by being puſhed hard againſt all the parts of the glaſs. When the glaſs is thus made quite ſmooth, it is puſhed to the bottom of the carquaiſſe, or annealing furnace, with a ſmall iron raker, and ranged there with a little iron hook. When the carquaiſſe is full, it is ſtopped and cemented as in the caſe of run glaſſes, and the glaſs remains there for a fortnight to be annealed; after which time, they are taken out to be poliſhed. A workman can make but one glaſs in an hour, and he works and reſts for ſix hours alternately.

It may be obſerved, that looking-glaſſes, thus blown, ſhould never be above forty-five, or at moſt fifty inches long, and of a breadth proportionable. Thoſe exceeding theſe dimenſions, as we frequently find among the Venice glaſſes, cannot have the thickneſs ſufficient to bear the grinding; and, beſides, are ſubject to warp, which prevents them from regularly reflecting objects. Whereas plates as large as nine feet in length and proportionally wide, have been manufactured by caſting.

Caſting or running large Looking-glaſs plates. This art, as we have obſerved in the *Hiſtory of* GLASS, is of French invention. It is owing to the Sieur Abraham Thevart, who firſt propoſed it to the court of France, in 1688

It is performed much like the caſting of ſheet-lead among the plumbers; and by means hereof we are not only enabled to make glaſſes of more than double the dimenſions of any made by the Venetian way of blowing; but alſo to caſt all kinds of borders, mouldings, &c.

The furnaces for melting the materials of this manufacture are of large ſize, being about 18 feet long and 15 wide; and thoſe for annealing the glaſſes, when formed, are much more ſo. Round a melting-furnace, there are at leaſt twenty-four annealing furnaces or ovens; each from twenty to twenty-five feet long; they are called carquaiſſes: each carquaiſſe has two tiſſarts, or apertures, to put in wood, and two chimnies. Add, that beſide the annealing furnaces, &c. there are others for making of frit, and calcining old pieces of glaſs.

All theſe furnaces are covered over with a large ſhed; under which are likewiſe forges, and work-houſes for ſmiths, carpenters, &c. continually employed in repairing and keeping up the machines, furnaces, &c. as alſo lodges, and apartments for theſe, and the other workmen, employed about the glaſs, and keeping up a perpetual fire in the great furnace; ſo that the glaſs-houſe, as that in the caſtle of St. Gobin, in the foreſt of Fere, in the Soiſſonois, appears more like a little city, than a manufactory.

The inſide of furnaces is formed of a ſort of baked earth, or refractory clay, proper to ſuſtain the action of fire; and the ſame earth ſerves alſo for melting-pots, ciſterns, &c. The furnaces ſeldom laſt above three years; after which they are to be rebuilt, from bottom to top; and to keep them good, even for that time, the inſide muſt be refitted every ſix months, at which time the fire is extinguiſhed. The ſmelting-pots are as big as wine hogſheads, about three feet in height, and in diameter; and contain above two thouſand weight of metal. They are in the form of an inverted and truncated cone. The ciſterns, or pans, called "cuvettes," are much ſmaller, being about thirty-ſix inches long, eighteen inches wide, and as many deep; and ſerve for the conveyance of liquid glaſs, which is drawn out of the pots to the caſting tables. They do not contain much more than a ſixth, or when large plates are caſt, a third of the pots.

When the furnace is in condition to receive the pots and ciſterns, they heat it red-hot, which requires fifty cords, or a hundred cart-loads of wood. That kind of wood which emits the largeſt and brighteſt flame, without much reſinous ſmoke, is preferred. This done, they fill the pots with the materials, or ſoda and ſand, which is done at ſeveral times, to facilitate the fuſion. When the matter is ſufficiently vitrified, refined, and ſettled, which uſually happens in thirty-ſix hours, they fill the ciſterns, which are in the ſame furnace, and which are left there about ſix hours longer, till ſuch time as they appear all white through the exceſſive heat.

To get the ciſterns with the metal out of the furnace, they make uſe of a large iron chain which opens and ſhuts with hooks and eyes. From the middle of this, on each ſide, ariſe two maſſive iron pins, by which, with the aſſiſtance of pullies, the ciſterns are raiſed upon a kind of carriage of a proper height; and thus conducted to the table where the glaſs is to be run. The ciſtern is then raiſed above the tables with an engine, in form of a crane, by means of two iron bars, ſo contrived as to throw the ciſtern into an inclined poſition, which diſcharges a torrent of matter, all on fire, with which the table prepared for this purpoſe is preſently covered.

The table on which the glaſs is to be run, is of ſmooth thick copper-plate, about ten feet long, and ſix feet broad. It is ſupported on a wooden frame, with truckles, for the convenience of removing from one carquaiſſe, or annealing furnace, to another, in proportion as they are filled.

Or, when each pot has a caſting table, it is ſtrongly ſupported by maſonry, and contiguous to each table on the ſame level are the annealing ovens, upon which, being flat, the glaſs, when caſt and ſufficiently cooled, may be ſlid from off the copper-table without much difficulty. The tops of the flat ovens and the tables are on a level with the correſponding opening of the furnace, whence the cuvettes or ciſterns are withdrawn. When the glaſs is melted and fined in the manner already ſtated under the article *Flint* Glass, the cuvette or ciſtern, previouſly made hot in the furnace, is filled out of the pot with a copper ladle, about ten inches in diameter, fixed to an iron handle ſeven feet long, properly ſupported on an iron ſtay by two workmen; and after remaining in the furnace for ſome hours, till the ſamples taken out for trial appear to be quite clear and limpid, the door of the furnace is opened, and the cuvette is pulled out and removed to the ſide of the copper table. It is then ſcummed with an inſtrument conſiſting of a copper blade ſet in iron, and hoiſted for the diſcharge of its contents on the table, in the manner already mentioned.

To form the thickneſs of a glaſs, and to make the ſurface ſmooth and even, there are two iron rulers or rims, placed round the edge of the table; and on theſe reſt the two extremes of a kind of roller, or hollow heavy cylinder of copper, turned after being caſt, and about 500 pounds in weight, which ſerves to drive the liquid matter before it to the end of the table, or mould. The iron rulers being moveable, and capable of being ſet cloſer, or farther apart, at pleaſure, determine the width of the glaſſes, and retain the matter, that it does not run off at the edges. The waſte glaſs, if any, falls into a veſſel of water, and is reſerved for the next melting.

As ſoon as the matter is arrived at the end of the table, and the glaſs is come to a conſiſtence, examined by the directors of the manufacture, and approved, they ſhove it off into the annealing furnace, with an iron raker, as wide as the table, that has a handle two fathoms long; being aſſiſted by workmen on the other ſide of the carquaiſſe, who, with iron hooks, pull the glaſs to them, and range it in the carquaiſſe, which holds ſix large glaſſes.

What is moſt ſurpriſing throughout the whole of this operation, is the quickneſs and addreſs wherewith ſuch maſſy ciſterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured on it, the glaſs ſpread, &c. The whole is inconceivable to ſuch as have not been eye-witneſſes of that ſurpriſing manufacture.

As faſt as the ciſterns are emptied, they carry them back to the furnace and take freſh ones, which they empty as before. This they continue to do, ſo long as there are any full ciſterns; laying as many plates in each carquaiſſe as it will hold, and ſtopping them up with doors of baked earth, or clay, and every chink with cement, as ſoon as they are full, to let them anneal, and cool again, which requires about fourteen days.

The firſt running being diſpatched, they prepare another, by filling the ciſterns anew, from the matter in the pots; and after the ſecond, a third, and even a fourth time, till the melting pots are quite empty.

The ciſterns at each running ſhould remain at leaſt ſix hours in the furnace to whiten; and when the firſt annealing furnace is full, the caſting table is to be carried to another. It need not here be obſerved, that the carquaiſſes, or annealing furnaces, muſt firſt have been heated to the degree proper for them. It may be obſerved, that the oven full, or the quantity of matter commonly prepared, ſupplies the running of eighteen glaſſes, which is performed in eighteen hours, being an hour for each glaſs. The workmen work ſix hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the ciſterns, to ſcrape off what glaſs remains, which otherwiſe would grow green by continuance of fire, and ſpoil the glaſſes. They are not filled again in leſs than thirty-ſix hours, ſo that they put the matter into the furnace, and begin to run it every fifty-four hours.

The manner of heating the large furnaces is ſingular enough; the two tiſors, or perſons employed for that purpoſe, in their ſhirts, run round the furnace without making the leaſt ſtop, with a ſpeed ſcarce inferior to that of the lighteſt courier: as they go along, they take two billets, or pieces of wood, which are cut for the purpoſe; theſe they throw into the firſt tiſſart; and continuing their courſe do the ſame for the ſecond. This they hold without interruption for ſix hours ſucceſſively; after which they are relieved by others, &c. It is ſurpriſing that two ſuch ſmall pieces of wood, and which are conſumed in an inſtant, ſhould keep the furnace to the proper degree of heat; which is ſuch, that a large bar of iron, laid at one of the mouths of the furnace, becomes red-hot in leſs than half a minute.

It is computed, that a furnace, before it be fit to run glaſs, coſts above three thouſand five hundred pounds; that at leaſt ſix months are required for the building it anew, and three months for the refitting it; and that when a pot of matter burſts in the furnace, the loſs of matter and time amounts to above two hundred and fifty pounds.

The glaſs, when taken out of the melting-furnace, needs nothing farther but to be ground, poliſhed, and foliated. But before theſe operations are performed, they cut and ſquare the edges of the plates; which is performed with a rough diamond, paſſed along the ſurface of the glaſs, upon a ſquare ruler, like that of the glaziers, and made to cut into the ſubſtance of the glaſs to a certain depth. This cut is then opened by gently knocking with a ſmall hammer on the under ſide of the glaſs, juſt under it; by which means the piece comes off, and the roughneſſes of the edges are removed by pincers. The plates are then laid by for *grinding*, *poliſhing*, and *ſilvering;* which ſee reſpectively. See alſo Looking-Glass.

Glass, *Annealing* or *Nealing of.* The operation of annealing of glaſs is performed in a peculiar furnace called the *leer*, which conſiſts of two parts, the *tower* and *leer.* The veſſels, as ſoon as made, are placed by the workmen on the floor of the former to anneal: which done, they are drawn ſlowly in a ſort of pan, called *fraches*, by an operator called the *ſarole-man*, all along the latter, the ſpace of five or ſix yards, to give them time to cool gradually; ſo that when they reach the mouth of it, they are found quite cold. Merret, Not. to Neri, p. 243, ſeq.

This annealing is generally performed in a hot chamber, built for the purpoſe, at the top of the glaſs-houſe, above the crucibles, and a little below the chimney. Without this precaution, the glaſs would be liable to fly and break, by the leaſt change of heat and cold, by the ſmalleſt ſcratch, and ſometimes without any apparent external cauſe. The hard glaſſes, and thoſe eſpecially that are made with alkali and earths, require much more annealing than the ſofter and more fuſible glaſſes, containing in their compoſition much litharge.

The particles of glaſs by annealing are ſuppoſed to loſe part of their ſpringineſs, and their brittleneſs at the ſame time. A gradual heating or cooling of glaſs, according to Dr. Hook, anneals or reduces its parts to a texture more looſe, and eaſy to be broke; but withal more flexible than before. And hence in ſome meaſure the phenomena of glaſs-drops.

Some of the phenomena depending on the fragility of unannealed glaſs deſerve the attention of the curious. Thoſe of the lachrymæ, or glaſs-drops, were among the firſt taken notice of; and it has alſo been obſerved, that hollow bells made of unannealed glaſs, with a ſmall hole in them, will fly to pieces by the heat of the hand only, if the hole by which the internal and external air communicate be ſtopped with a finger. Phil. Tranſ. N° 477. § 3. See Rupert's *Drops*.

But lately ſome veſſels made of ſuch unannealed glaſs have been diſcovered, which have the remarkable property of reſiſting very hard ſtrokes given from without, though they ſhiver to pieces by the ſhocks received from the fall of very light and minute bodies dropped into their cavities. Of this kind is the "Bologna phial." Theſe glaſſes may be made of any ſhape; all that needs be obſerved in making them, is to take care that their bottoms may be thicker than their ſides. The thicker the bottom is, the eaſier do the glaſſes break. One whoſe bottom is three fingers breadth in thickneſs, flies with as much eaſe at leaſt as the thinneſt glaſs. Some of theſe veſſels have been tried with ſtrokes of a mallet ſufficient to drive a nail into wood tolerably hard, and have reſiſted fracture. They alſo reſiſt the ſhock of ſeveral heavy bodies let fall into their cavities, from the height of two or three feet. For inſtance, muſket-balls, pieces of iron, or other metal; pyrites, jaſper, wood, bone, &c. but this is not ſurpriſing, as other glaſſes of the ſame ſize do the ſame. But the wonder is, that taking a ſhiver of flint of the ſize of a ſmall pea, and letting it fall into the glaſs only from the height of three inches, in about two ſeconds the glaſs flies, and ſometimes in the very moment of the ſhock; nay a bit of flint, no larger than a grain, dropt into ſeveral glaſſes ſucceſſively, though it did not immediately break them, yet they all flew, being ſet by, in leſs than three quarters of an hour. Phil. Tranſ. ibid. p. 509.

Some other bodies produce a like effect with flint: for inſtance, ſapphire, porcelain, diamonds, hard tempered ſteel, as alſo marbles, ſuch as boys play with; to which add pearls from the animal kingdom.

The experiment ſucceeded alſo when the glaſſes were held in the hand, reſted on a pillow, put in water, or filled with water. It is alſo remarkable, that the glaſſes broke upon their bottoms being ſlightly rubbed with the finger, though ſome of them did not fly till half an hour after the rubbing.

If the glaſſes be every where extremely thin, they do not break in theſe circumſtances.

Some have pretended to account for theſe phenomena, by ſaying, that the bodies dropped into theſe veſſels cauſe a concuſſion, that is ſtronger than the coheſion of the parts of the glaſs, and that conſequently a rupture of the ſame muſt enſue. But why does not a ball of gold, ſilver, iron, copper, or ſeveral other bodies, even a thouſand times heavier than a ſhiver of flint, equally cauſe this concuſſion, and break the glaſſes?

Mr. Euler has endeavoured to account for theſe appearances from his Principles of Percuſſion. He thinks this experiment entirely overthrows the opinion of thoſe who meaſure the force of percuſſion by the *vis viva;* and he thinks the principles he has eſtabliſhed give a clear ſolution of this phenomenon. According to theſe principles, the extreme hardneſs of the flint, and alſo its angular figure, which makes the ſpace of contact with the glaſs veſſel extremely ſmall, ought to cauſe an impreſſion on the glaſs vaſtly greater than lead or any other metal; and this may account for the flint's breaking the veſſel, though the bullet, even falling from a conſiderable height, does no damage. Mem. Acad. Berlin, 1745, p. 47.

Hollow cups, made of the green bottle-glaſs, ſome of them three inches thick at bottom, were inſtantly broken, by a ſhiver of flint weighing about two grains, though they had reſiſted the ſhock of a muſket ball from the height of three feet. Phil. Tranſ. ibid. p. 515.

"The preciſe mechanical cauſe of this diſpoſition to crack in unannealed glaſs, is very difficult to explain," ſays Aikin (Dict.), "but generally ſpeaking, it is ſuppoſed to be the forcible contraction of the outer part by ſudden cooling, whilſt the inner portion is ſtill ſoft and half-fluid, ſo that the whole fixes with a permanent ſtrain or inequality of preſſure of one part upon the other; and as glaſs is extremely elaſtic, though brittle, any force which tears aſunder a portion, however ſmall, of the tenſe part, communicates a ſtrong and ſudden impulſe over the whole maſs." "This moſt ſingular phenomenon," (of the Rupert's drop) ſays the ſame ingenious chemiſt, in conſequence of his own experiments, "is obviouſly owing to ſome permanent and very ſtrong inequality of preſſure; for when they are heated ſo red, as to be ſoft and merely let to cool of themſelves, this property of burſting is entirely loſt, and, at the ſame time, the ſpecific gravity of the drop is increaſed. The peculiar brittleneſs of the Bologna phial is alſo removed by again heating and cooling ſlowly." The common window-glaſs, when badly annealed, is cut by the diamond with difficulty, and the cut often flies in a direction different from what was intended, or the glaſs entirely breaks.

Among other more common defects of glaſs, we may mention its liability to be acted upon by corroſive liquors, as is the caſe when too much ſaline flux has been uſed. As impenetrable as glaſs is to the common menſtruums, we find it eaten by the air in length of time, when expoſed in old windows; but the effects of its being kept in a ſubterraneous place are much more ſtrange. Borrichius tells us, that at the time when he was at Rome, there was dug up a whole houſe from under the kitchen garden of a citizen. The houſe had been buried there ten ages, and there were found in it ſeveral glaſs urns, or lacrymatories. The glaſs of theſe had no holes made in it, as our old glaſs in chamber-windows has, but ſtill retained its ſmooth ſurface and tranſparence; but it was ſplit into a vaſt number of thin laminæ, which were as pellucid and fine as Muſcovy glaſs; and in ſome places were tinged with all the beautiful colours that art could have given. We are not acquainted perfectly with the ancient way of working their glaſs; but it is not probable there could be any thing particular in the formation of the veſſel, to determine it to ſplit thus into flakes; but that glaſs of the ſame kind, in any form, would have done the ſame. Borrich. de Ortu Chemiæ.

There are other viſible imperfections in glaſs, materially injuring its ſoundneſs and beauty, and enumerated by Aikin (Dict. art. *Glaſs*) under the denominations of *ſtriæ, threads, tears,* and *knots.* The former are undulating waves in the glaſs, ariſing from the imperfect mixture of the materials, and their different ſpecific gravities. Accordingly, we may obſerve, that the moſt tranſparent glaſs is ſubject to bubbles and veins, the methods of preventing which are yet little known; and this is an inconvenience by which Mr. Dollond's excellent diſcovery is affected; for the flint-glaſs which he uſes is peculiarly ſubject to ſmall veins, that diſturb the rays in their paſſage, and render the viſion confuſed. This effect is owing to the denſity of theſe veins being greater than that of the reſt of the glaſs, as appears from their image received on white paper, when the glaſs is held between the paper and a candle, or other luminous object: for this image of a vein, thus received, is a line brighter than the reſt of the image of the glaſs, and this bright line is defined by a dark edge on each ſide. But the bright line evidently ſhews a convergency of rays, which can only be effected by the veins being denſer than the medium in which they are placed. The reaſon why flint glaſs is more ſubject to veins than other glaſs is, ſays the tranſlator of Macquer's Chemical Dictionary, becauſe it is compoſed of materials of more different denſities.

Mr. Macquer, with a view of improving the manufacture of this glaſs, propoſes to facilitate the union of the calx of lead and ſand, of which it is compoſed, by depriving the calx of lead, as much as poſſible, of its phlogiſton, which may be done by combining the vitriolic acid with minium, or red-lead, and expoſing this compoſition to the operation of fire, to diſengage it from the acid; and alſo by giving theſe two ſubſtances the greateſt poſſible degrees of fluidity and mobility, which may be done by mixing with the compoſition of them a conſiderable quantity of ſolvents. Hiſt. Acad. Scienc. for 1773.

Threads in glaſs, are thoſe ſtreaky filaments which ariſe from the vitrification of the clay; being generally green, and rendering the glaſs more liable to crack at theſe parts. But one of the worſt defects (ſays Aikin, *ubi ſupra*), is "*tears,* or drops of vitrified clay falling down from the furnace into the pots, and entangled with the glaſs. Articles made of glaſs with this defect, are always very brittle, and generally break of themſelves by ſlight changes of heat and cold." Small bubbles appear in glaſs not ſufficiently refined by a continuance of the melting heat; and theſe may be owing to a deficiency of flux, ſo that the glaſs is leſs fuſible, and the bubbles cannot eaſily be diſengaged. "Hence," ſays the author now cited, "the ſoft fuſible glaſſes with much lead are much leſs liable to this fault than the hard, green bottle-glaſs, which is made only of alkali and earth." The *knots* in glaſs "ariſe either from a portion of ſand that has eſcaped vitrification, and remains entangled in the glaſs, or from a remaining quantity of glaſs-gall; or from bits of the crucible which may be accidentally knocked off by the iron inſtruments uſed in the working."

GLASS *of Antimony.* See *Oxyds of* ANTIMONY and VITRUM *Antimonii ceratum.*

GLASS, *Axungia of.* See AXUNGIA, SANDIVER, and GLASS, *ſupra.*

GLASS *of Borax.* See BORAX.

GLASS, *Colouring of, to imitate gems.* See GEMS.

GLASS, *Gold-coloured.* This kind of glaſs may be made by taking ten pounds of either of the compoſitions for hard glaſs, omitting the ſalt-petre; and for every pound adding an ounce of calcined borax; or, if this quantity doth not render the glaſs ſufficiently fuſible, two ounces; ten ounces of red tartar, of the deepeſt colour, two ounces of manganeſe, and two drams of charcoal of ſallow, or any other ſoft kind. Precipitate of ſilver baked on glaſs will ſtain it yellow, and likewiſe give a yellow colour on being mixed with and melted with forty or fifty times their weight of vitreous compoſitions; the precipitate from aqua-fortis by fixed alkali ſeems to anſwer beſt. Yellow glaſſes may alſo be obtained with certain preparations of iron, particularly with Pruſſian blue. But Dr. Lewis obſerves, that the colour does not conſtantly ſucceed, nor approach to the high yellow of gold, with ſilver or with iron. The neareſt imitations of gold which he has been able to produce, have been effected with antimony and lead. Equal parts of the glaſs of antimony, of flint calcined and powdered, and of minium, formed a glaſs of a high yellow; and with two parts of glaſs of antimony, two of minium, and three of powdered flint, the colour approached ſtill more to that of gold. The laſt compoſition exhibited a multitude of ſmall ſparkles interſperſed through its whole ſubſtance, which gave it a beautiful appearance in the maſs, but were really imperfections, owing to air-bubbles.

Neri directs, for a gold-yellow colour, one part of red tartar, and the ſame quantity of manganeſe, to be mixed with a hundred parts of frit. But Kunckel obſerves, that theſe portions are faulty; that one part, or one and a quarter of manganeſe, is ſufficient for a hundred of frit; but that ſix parts of tartar are hardly enough, unleſs the tartar is of a dark red colour, almoſt blackiſh; and that he found it expedient to add to the tartar about a fourth of its weight of powdered charcoal. He adds, that the glaſs ſwells up very much in melting, and that it muſt be left unſtirred and worked as it ſtands in fuſion. Mr. Samuel More, in repeating and varying this proceſs, in order to render the colour more perfect, found that the manganeſe is entirely eſſential to the gold colour, and that the tartar is no otherwiſe of uſe, than in virtue of the coaly matter, to which it is in part reduced by the fire; the phlogiſton or inflammable part of the coal appearing in ſeveral experiments to be the direct tinging ſubſtance. Mr. Pott alſo, in his Neue Wichtige Phyſicaliſhch-Chymiſche Materien, &c. printed in 1762, obſerves, that common coals give a yellow colour to glaſs; that different coaly matters differ in their tinging power; that caput mortuum of ſoot and lamp-black anſwer better than common charcoal; and that the ſparkling coal which remains in the retort after the rectification of the thick empyreumatic animal oils, is one of the moſt active of theſe preparations. This preparation, he ſays, powdered, and then burnt again a little in a cloſe veſſel, is excellent for tinging glaſs, and gives yellow, brown, reddiſh, or blackiſh colour, according to its quantity: but the frit muſt not be very hard of fuſion; for, in this caſe, the ſtrong fire will deſtroy the colouring ſubſtance before the glaſs melts, and he has found the following compoſitions to be nearly the beſt; *viz.* ſand two parts, alkali three parts; or ſand two, alkali three, calcined borax one; or ſand two, alkali two, calcined borax one: and though ſalt-petre is hardly uſed at all, or very ſparingly, for yellow glaſſes, as it too much volatilizes the colouring ſubſtance; yet here for the moſt part a certain proportion of it, eaſily determined by trial, is very neceſſary; for without it, the concentrated colouring matter is apt to make the glaſs too dark, and even of an opaque pitchy blackneſs. It does not certainly appear that there is any material diverſity in the effects of different coals; the difference being probably owing to the different quantities of the inflammable matter which they contain; ſo that a little more ſhall be required of one kind than of another, for producing the ſame degree of colour in the glaſs. Nor does the ſoftneſs or fuſibility of the frit appear to be in any reſpect neceſſary.

Gold-coloured ſpangles may be diffuſed through the ſubſtance of glaſs, by mixing the yellow talcs with powdered glaſs, and bringing the mixture into fuſion. See Lewis's Com. Phil. Techn. p. 223. 626, &c.

Glass *for counterfeiting lapis lazuli.* See *Lapis* Lazuli.

Glass *reſembling opal.* See Opal and Gems.

Glass, *Ruby.* The way to give the true fine red of the ruby, with a fair tranſparence, to glaſs, is as follows. Calcine in earthen veſſels gold diſſolved in aqua regia, the menſtruum being evaporated by diſtillation, more aqua regia added, and the abſtraction repeated five or ſix times, till it becomes a red powder. This operation will require many days in a hot furnace; when the powder is of a proper colour, take it out; and when it is to be uſed, melt the fineſt cryſtal glaſs, and purify it, by often caſting it into water; and then add, by ſmall quantities, enough of this red powder to give it the true colour of a ruby, with an elegant and perfect tranſparence. Neri. See Gems.

The proceſs of tinging glaſs and enamels by preparations of gold, were firſt attempted about the beginning of the 17th century. Libavius, in one of his tracts, entitled Alchymia, printed in 1606, conjectures that the colour of the ruby proceeds from gold, and that gold diſſolved, and brought to redneſs, might be made to communicate a like colour to factitious gems and glaſs. On this principal Neri, in his "Art of Glaſs," dated 1611, gives the proceſs above recited. Glauber, in 1648, publiſhed a method of producing a red colour by gold, in a matter which is of the vitreous kind, though not perfect glaſs. For this purpoſe he ground powdered flint or ſand with four times its weight of fixed alkaline ſalt; this mixture melts in a moderately ſtrong fire, and when cold looks like glaſs, but expoſed to the air runs into a liquid ſtate. On adding this liquor to ſolution of gold in aqua regia, the gold and flint precipitate together in form of a yellow powder, which by calcination becomes purple; by mixing this powder with three or four times its weight of the alkaline ſolution of flint, drying the mixture, and melting it in a ſtrong fire for an hour, a maſs is obtained, of a tranſparent ruby colour, and of a vitreous appearance, which nevertheleſs is ſoluble in water, or by the moiſture of the air, on account of the redundance of the ſalt. The honourable Mr. Boyle, in a work publiſhed in 1680, mentions an experiment, in which a like colour was introduced into glaſs without fuſion; for, having kept a mixture of gold and mercury in digeſtion for ſome months, the fire was at laſt immoderately increaſed, ſo that the glaſs burſt with a violent exploſion; and the lower part of the glaſs was found tinged throughout of a tranſparent red colour, hardly to be equalled by that of rubies. See Poroſity of Bodies, in Shaw's Abridgment of Boyle's Works, vol. i. p. 459; and Appendix to the Sceptical Chemiſt.

About the ſame time Caſſius is ſaid to have diſcovered the precipitation of gold by tin, and that glaſs might be tinged of a ruby colour by melting it with this precipitate: though he does not appear, ſays Dr. Lewis, from his treatiſe De Auro, to have been the diſcoverer of either. He deſcribes the preparation of the precipitate and its uſe, but gives no account of the manner of employing it; only that he ſays, one dram of gold, duly prepared, will tinge ten pounds of glaſs. See Gold *precipitate with tin.*

This proceſs was ſoon after brought to perfection by Kunckel; who ſays, that one part of the precipitate is ſufficient to give a ruby colour to 1280 parts of glaſs, and a ſenſible redneſs to upwards of 1900 parts; but that the ſucceſs is by no means conſtant. Kunckel alſo mentions a purple-gold powder, reſembling that of Neri, which he obtained by inſpiſſating ſolution of gold to dryneſs, abſtracting from it freſh aqua regia three or four times, till the matter appears like oil; then precipitating with ſtrong alkaline ley, and waſhing the precipitate with water. By diſſolving this powder in ſpirit of ſalt, and precipitating it again, it becomes, he ſays, extremely fair; and in this ſtate he directs it to be mixed with a due proportion of Venice glaſs.

Orſchal in his treatiſe entitled Sol ſine Veſte, gives the following proceſs for producing a very fine ruby. He directs the purple precipitate, made by tin, to be ground with ſix times its quantity of Venice-glaſs into a very fine powder, and this compound to be very carefully mingled with the frit or vitreous compoſition to be tinged. His frit conſiſts of equal parts of borax, nitre, and fixed alkaline ſalt, and four times as much calcined flint as of each of the ſalts; but he gives no directions as to the proportion of the gold precipitate, or mode of fuſion. Hellot deſcribes a preparation, which mixed with Venice glaſs, was found to give a beautiful purple enamel. This preparation conſiſts of equal parts of ſolution of gold, and of ſolution of zinc in aqua regia, mixed together with the addition of a volatile ſalt prepared from ſal ammoniac, in quicklime, in ſufficient quantity to precipitate the two metals. The precipitate is then gradually heated, till it acquires a violet colour. However, though a purple or red colour, approaching to that of ruby, may, by the methods above recited, be baked on glaſs or enamels, and introduced into the maſs by fuſion, the way of equally diffuſing ſuch a colour through a quantity of fluid glaſs is ſtill, ſays Dr. Lewis, a ſecret. The following proceſs for making the ruby glaſs was communicated to Dr. Lewis by an artiſt, who aſcribed it to Kunckel. The gold is directed to be diſſolved in a mixture of one part of ſpirit of ſalt, and three of aqua-fortis, and the tin in a mixture of one part of the former of theſe acids with two of the latter. The ſolution of gold being properly diluted with water (ſee Gold *precipitate,* &c.) the ſolution of tin is added, and the mixture left to ſtand till the purple matter has ſettled to the bottom. The colourleſs liquor is then poured off, and the purple ſediment, while moiſt and not very thick, is thoroughly mixed with powdered flint or ſand. This mixture is well ground with powdered nitre, tartar, borax, and arſenic, and the compound melted with a ſuitable fire. The proportions of the ingredients are 2560 parts of ſand, 384 of nitre, 240 of tartar, 240 of borax, 28 of arſenic, 5 of tin, and 5 of gold. Lewis's Com. Phil. Techn. p. 171. 621, &c.

Glass, *white-opaque,* and *ſemi-tranſparent,* may be made of ten pounds of either of the compoſitions for hard glaſs, and one pound of well calcined horn, ivory, or bone; or an opaque whiteneſs may be given to glaſs, by adding one pound of very white arſenic to ten pounds of flint glaſs. Let them be well powdered and mixed, by grinding them together; and then fuſed with a moderate heat, till they are thoroughly incorporated. A glaſs of this kind is made in large quantities at a manufacture near London, and uſed not only for different kinds of veſſels, but as a white ground for enamel in dial-plates and ſnuff-boxes, which do not require finiſhing with much fire, becauſe it becomes very white and fuſible with a moderate heat.

Glass, *Yellow*. See *Golden-coloured* Glass.

Glass-*balls*, which are circular or otherwiſe ſhaped hollow veſſels of glaſs, may be coloured within, ſo as to imitate the ſemi-pellucid gems. The method of doing it is this: make a ſtrong ſolution of ichthyocolla, or iſinglaſs, in common water, by boiling; pour a quantity of this while warm into the hollow of a white glaſs veſſel; ſhake it thoroughly about, that all the ſides may be wetted, and then pour off the reſt of the moiſture. Immediately after this, throw in red lead, ſhake it and turn it about, throw it into many places with a tube, and the moiſture will make it ſtick and run in waves and pretty figures. Then throw in ſome of the painter's blue ſmalt, and make it run in waves in the ball as the red-lead; then do the ſame with verdigris, next with orpiment, then with red lake, all well ground; always caſting in the colours in different places, and turning the glaſs, that the moiſture within may run them into the waves. Then take fine plaſter of Paris, and put a quantity of it into the ball; ſhake it alſo nimbly about; this will every where ſtick firmly to the glaſs, and give it a ſtrong inner coat, keeping all the colours on very fairly and ſtrongly.

Theſe are ſet on frames of carved wood, and much eſteemed as ornaments in many places. Neri.

Glass-*drops*. See Rupert's *drops*.

Glass, *Foliating of*. See Foliating and Looking-glass.

Glass-*gall*, or *ſandiver*, is the ſcum of the glaſs pots, which ariſes during the vitrification of the frit. See Glass, *ſupra*.

Glass, *gilding of*. See Gilding *of enamel* and *glaſs*.

Glass, *grinding of*. See Grinding.

Glass-*houſe Furnace*, is the place in which the ingredients or materials of glaſs are fuſed and vitrified. There are three kinds of furnaces uſed in the glaſs-works. The *firſt*, called the "calcar," ſerves for preparing or calcining the frit. It is made like an oven, 10 feet long, ſeven broad, and two deep. The fuel, which is ſea-coal, is put in a trench, on one ſide of the furnace; and the flame reverberates from the roof back upon the frit. The coals burn in an iron grate, and the aſhes fall thence into holes underneath.

The *ſecond* is the "working furnace," in which the ingredients are melted, and the glaſs is made. Its figure is round, reſembling a dome, three yards in diameter, and two high, ſupported on arches, beneath which is a large ſpace for a briſk and copious draught of cold air from without: round the inſide there are arranged eight or more pots, and on theſe piling-pots, every where cloſed except at one ſide opening, which communicates with a ſmall receſs formed by the alternate projections of the maſonry and flues of the oven or kiln, in which receſs the workmen ſtand. The furnace has two partitions; the lower, ſeparating the pots from the fire-place, has a circular hole in the centre covered with a grate, through which the flame paſſes from the fire-place into the furnace, being afterwards reverberated from the arched ſides and roof to the melting-pots, and paſſing out with the ſmoke through the top of the dome, which is lengthened into a chimney for the ſpace of a few feet. The ſecond partition divides this from the leer or annealing furnace; through the boccas, or working holes, when there are more than one, the metal is taken out of the pots, and the pots put into the furnace: theſe boccas are ſtopped with moveable covers, made of lute and brick to ſcreen the eyes of the workmen from the fire; and ſometimes on each ſide of the bocca is a boccarella, out of which coloured glaſs, or finer metal is taken from the piling-pot. To the furnace likewiſe occaſionally belong ovens, or holes near the leer, for the calcining of tartar, iron, &c.

The leer, which ſerves to anneal and cool the veſſels, and which Agricola makes a particular furnace, conſiſts of a tower, beſides the leer; the tower lies directly over the melting furnace, with a partition betwixt them about a foot thick, having an aperture called *occhio*, or *lumella*, through which the flame or heat aſcends out of the furnace into the tower: on the floor or bottom of this tower, the veſſels, faſhioned by the artiſt, are ſet to be annealed; and as the flame has here a leſs degree of intenſity than that which is ſuſtained by the pots, the veſſels, after they have been formed, cool ſlowly and gradually. This has uſually two boccas, or mouths, by which the glaſſes are put in with a fork, and placed on the floor. The *leer* is an avenue, five or ſix yards long, continued to the tower; through this the glaſſes, when annealed, are drawn in iron pans, called *fraches*, by which they come to cool by degrees, being quite cold by the time they reach the mouth of the leer, which enters the "ſaroſel," or room where the glaſſes are to be ſet.

The *third* is the "green-glaſs furnace," which is a kind of compound of all the former. It is made ſquare, (the two former being circular,) having an arch at each angle for annealing and cooling the glaſſes. The metal is wrought on two oppoſite ſides, and on the other two they have their calcars, into which are made linnet-holes for the fire to come from the furnace, to bake the frit, and alſo to diſcharge the ſmoke. Fires are made in the arches to anneal the veſſels, ſo that the whole proceſs is done in one furnace. The materials with which the inſides of theſe furnaces are conſtructed are not ordinary brick (which would ſoon melt down into glaſs, as would alſo all the ſofter ſtones,) but hard and ſandy kinds, called by Imperatus "pyramachia." But when bricks are uſed, they ſhould be formed of an earth which poſſeſſes in the higheſt degree the qualities of denſity and infuſibility, for reſiſting the fire, which continues to act upon them, without ceſſation for a long time; as the fires in a glaſs-houſe are ſeldom ſuffered to go out, from the time when the furnace is firſt employed till it needs repair, and the interval may be two or three years; the walls of the furnace, for this reaſon, as well as the pots, are conſtructed chiefly of clay, mixed with ſand, and other materials of a refractory kind, in due proportion. See Glass-*pots*.

Glass *of lead*, a glaſs made with the addition of a large quantity of lead, of great uſe in the art of making counterfeit gems. The method of making it is this: put a large quantity of lead into a potter's kiln, and keep it in a ſtate of fuſion with a moderate fire, till it is calcined to a grey looſe powder: then ſpread it in the kiln, and give it a greater heat, continually ſtirring it to keep it from running into lumps; continue this ſeveral hours, till the powder become of a fair yellow; then take it out and ſift it fine: this is called calcined lead.

Take of this calcined lead fifteen pounds, and cryſtalline, or other frit, twelve pounds; mix theſe as well as poſſible together; put them into a pot, and ſet them in the furnace for ten hours; then caſt the whole, which will be now perfectly melted, into water; ſeparate the looſe lead from it, and return the metal into the pot; and after ſtanding in fuſion twelve hours more, it will be fit to work. It is very tender and brittle, and muſt be worked with great care, taking it ſlowly out of the pot, and continually wetting the marble it is wrought upon. Neri.

It is well known, that ceruſs, or white lead, minium, litharge, and all the other preparations and calces of lead, are eaſily fuſed by a moderate fire, and formed into a tranſparent glaſs of a deep yellow colour. But this glaſs is ſo penetrating and powerful a flux, that it is neceſſary to give it a greater conſiſtence, in order to render it fit for uſe. With this view, two parts of calx of lead, *e. g.* minium, and other parts of ſand, or powdered flints, may be put into a crucible of refractory clay, and baked into a compact body. Let this crucible, well cloſed with a luted lid, be placed in a melting furnace, and gradually heated, for an hour, or an hour and a half; and afterwards let the heat be increaſed, ſo as to obtain a complete fuſion, and continued in that ſtate for the ſame time: let this crucible remain to cool in the furnace, and when it is broken, a very tranſparent yellow-coloured glaſs will be found in it. Some add nitre and common ſalt to the above mixture, becauſe theſe ſalts promote the fuſion and the more equal diſtribution of the ſand. This glaſs of lead has a conſiderable ſpecific gravity, and its loweſt part is always the heavieſt. It is an important flux in the aſſays of ores to facilitate their ſcorifications.

Glaſs of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are theſe: for green, take polverine frit twenty pounds, lead calcined ſixteen pounds; ſift both the powders very fine; then melt them into a glaſs, ſeparating the unmixed lead, by plunging the maſs in water; after this return it into the pot, and add braſs thrice calcined ſix ounces, and one pennyweight of crocus martis made with vinegar; put this in at ſix different times, always carefully mixing it together; let it finally ſettle an hour, then mix it together, and take a proof of it; when the colour is right, let it ſtand eight hours, and then work it. If inſtead of the calcined braſs the ſame quantity of the caput mortuum of the vitriolum veneris be uſed, the green is yet much finer.

For topaze-colour take cryſtal frit fifteen pounds, calcined lead twelve pounds; mix them well together, by ſifting the powders through a fine ſieve; then ſet them in a furnace not too hot, and ſeparate the ſuperfluous unmixed lead, by caſting the whole into water: repeat this twice; then add half gold yellow glaſs, and let them incorporate and purify, and they will be of the true and exact colour of the original topazes.

For ſea-green, take cryſtal frit ſixteen pounds, calcined lead ten pounds; mix and ſift them together, and ſet them in a pot in a furnace: in twelve hours the whole will be melted; then caſt it into water and ſeparate it from the looſe lead; put them into the furnace again for eight hours; then ſeparate the looſe lead by waſhing a ſecond time, and return it to the pot for eight hours more. Neri. See GEMS.

GLASS, *Painting in.* The primitive manner of painting in glaſs was very ſimple, and of conſequence very eaſy: it conſiſted in the mere arrangement of pieces of glaſs of different colours, in ſome ſort of ſymmetry; and conſtituted a kind of what we call *Moſaic work.*

Afterwards, when they came to attempt more regular deſigns, and even to repreſent figures raiſed with all their ſhades, their whole addreſs went no farther than to the drawing the contours of the figures in black, with water colours, and hatching the draperies, after the ſame manner, on glaſſes of the colour of the object intended to be painted. For the carnations, they choſe glaſs of a bright red; upon which they deſigned the principal lineaments of the face, &c. with black.

At laſt the taſte for this ſort of painting being conſiderably improved, and the art being found applicable to the adorning of churches, baſilicas, &c. they found means of incorporating the colours with the glaſs itſelf, by expoſing them to a proper degree of fire, after the colours had been laid on.

A French painter at Marſeilles is ſaid to have given the firſt notion hereof, upon going to Rome, under the pontificate of Julius II. But Albert Durer, and Lucas of Leyden, were the firſt that carried it to any height.

The colours uſed in painting on glaſs are very different from thoſe uſed either in painting in oil, or water.

The *black* is made of two-thirds of flakes, or ſcales of iron, beaten up, and mixed with another third of rocaille, or little glaſs beads. *White,* with ſand, or little white pebbles, calcined, pounded in a mortar, and afterwards ground on marble; with one fourth-part of ſalt-petre, added thereto, and the mixture calcined and pulverized over again: to which, when they are ready to uſe it, is added a little gypſum, or plaſter of Paris well ground, &c. For *yellow,* they uſe leaf-ſilver ground, mixed up in a crucible, with ſulphur or ſalt-petre; then well beaten and ground on a porphyry ſtone; and, at length, ground over again with nine times as much red ochre. *Red* is made of litharge of ſilver, and ſcales of iron, gum Arabic, ferretta, glaſs-beads, and blood-ſtone, nearly in equal quantities. This is one of the moſt difficult colours, and the preparation only to be learned by experience. *Green* is made of æs uſtum, one ounce; as much black lead, and four ounces of white ſand, incorporated by the fire. After calcination, they add a fourth part of ſalt-petre: after a ſecond calcination, a ſixth part more: after which they make a third coction before it is uſed. *Azure, purple,* and *violets,* are prepared like green, only leaving out the æs uſtum, and in the lieu thereof uſing ſulphur for azure; perigueux for purple; and both theſe drugs for violet. *Carnations* are made of ferretta and rocaille. And laſtly, colours for the hair, trunks of trees, &c. are made of ferretta, rocaille, &c.

This account of colours we have from M. Felibien's excellent work Des Principes d'Architecture, &c. though it muſt be owned, that all the painters on glaſs do not uſe them; there being few artiſts of that kind but have invented their own particular ones, whereof they uſually make great ſecrets. But this is certain, that theſe above deſcribed are ſufficient for the beſt paintings of all ſorts; provided the perſon has but the ſkill to manage them.

In the windows of divers ancient churches, chapels, colleges, &c. we meet with the moſt beautiful and lively colours imaginable; ſuch as far exceed any uſed among us: but it is not that the ſecret of making thoſe colours is loſt; but that the moderns would not go to the expence of them; nor take all the neceſſary pains; becauſe this ſort of painting is not now ſo much eſteemed as formerly.

Mr. Walpole, in his Anecdotes of painting in England, has traced the hiſtory of this art from the reformation, when miſguided zeal deſtroyed moſt of the monuments of it in our churches, through a ſeries of profeſſors to the preſent time. Among the later proficients in this art were Iſaac Oliver, who painted the windows at Chriſtchurch, Oxford, in 1700; William Price, who in the ſame year painted the windows in Merton chapel; William Price, the ſon, to whoſe art we owe the windows at Queen's, New-college, and Maudlin, of whom Mr. Walpole ſays, that his colours are fine, his drawing good, and his taſte in ornaments and Moſaic far ſuperior to any of his predeceſſors, and equal to the antique. In 1761, Mr. Paterſon, an auctioneer late of Eſſex-houſe in London, exhibited the two firſt auctions of painted glaſs imported from Flanders; and undertook alſo to eſtabliſh a manufacture of painted glaſs: ſeveral of the pieces of this ingenious artiſt exhibited colours vying in perfection with the old paintings.

Thoſe beautiful works, among the painters in glaſs, which were made in the glaſs-houſe, were of two kinds: in ſome, the colour was diffuſed through the whole body of glaſs; in others, which were the more common, the colour was only on one ſide, ſcarce penetrating within the ſubſtance above one-third of a line; though this was, more or leſs, according to the nature of the colour; the yellow being always found to enter the deepeſt.

Theſe laſt, though not ſo ſtrong and beautiful as the former, were of more advantage to the workmen; becauſe, on the ſame glaſs, though already coloured, they could ſhew other kinds of colours, where there was occaſion to embroider draperies, enrich them with foliages, or repreſent other ornaments of gold, ſilver, &c.

In order to this, they made uſe of emery; grinding, or wearing down the ſurface of the glaſs, till ſuch time as they were got through the colour, to the clear glaſs: this done, they applied the proper colours on the other ſide of the glaſs. By this means the new colours were prevented from running and mixing among the former, when the glaſſes came to be expoſed to the fire, as will hereafter be ſhewn.

When the intended ornaments were to appear white, or ſilvered, they contented themſelves to bare the gloſs of its colour with emery, without applying any new colour at all; and it was in this manner that they wrought the lights and heightenings on all kinds of colours.

The painting with vitreous colours on glaſs depends entirely on the ſame principles as painting in enamel; and the manner of executing it is likewiſe the ſame; except that in this the tranſparency of the colours being indiſpenſibly requiſite, no ſubſtances can be uſed to form them but ſuch as vitrify perfectly: and, therefore, the great object is to find a ſet of colours, which are compoſed of ſuch ſubſtances, as, by the admixture of other bodies, may promote their vitrification and fuſion; are capable of being converted into glaſs; and melting, in that ſtate, with leſs heat than is ſufficient to melt ſuch other kinds of glaſs as may be choſen for the ground or body to be painted; to temper theſe colours, ſo as to make them proper to be worked with a pencil; and to burn or reduce them by heat, to a due ſtate of fuſion, without injuring or melting the glaſs which conſtitutes the body painted. The firſt thing to be done, in order to paint on glaſs, in the modern way, is to deſign, and even colour, the whole ſubject on paper. Then they make choice of pieces of glaſs proper to receive the ſeveral parts, and proceed to divide or diſtribute the deſign itſelf, or the paper it is drawn on, into pieces ſuitable to thoſe of glaſs; having always a view that the glaſſes may join in the contours of the figures, and the folds of the draperies; that the carnations and other finer parts may not be damaged by the lead wherewith the pieces are to be joined together.

The diſtribution being made, they mark all the glaſſes, as well as papers, with letters, or numbers, that they may be known again; which done, applying each part of the deſign on the glaſs intended for it, they copy or transfer the deſign upon this glaſs, with the black colour, diluted in gum-water; by tracing and following all the lines and ſtrokes, as they appear through the glaſs, with the point of a pencil.

When theſe firſt ſtrokes are well dried, which happens in about two days, the work being only in black and white, they give it a ſlight waſh over, with urine, gum Arabic, and a little black; and this ſeveral times repeated, according as the ſhades are deſired to be heightened; with this precaution, never to apply a new waſh, till the former is ſufficiently dried. This done, the lights and riſings are given, by rubbing off the colour in the reſpective places, with a wooden point or the handle of the pencil.

As to the other colours above-mentioned, they are uſed with gum-water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing the outlines of the deſign; or even, for the greater ſecurity, to apply them on the other ſide, eſpecially yellow, which is very pernicious to other colours, by blending therewith.

And here too, as in pieces of black and white, particular regard muſt be always had, not to lay colour on colour, or lay on a new lay, till ſuch time as the former are well dried. It may be added, that the yellow is the only colour that penetrates through the glaſs, and incorporates therewith by the fire; the reſt, and particularly the blue, which is very difficult to uſe, remaining on the ſurface, or at leaſt entering very little. When the painting of all the pieces is finiſhed, they are carried to the furnace or oven, to anneal or bake the colonrs. The furnace here uſed is ſmall, built of brick, from eighteen to thirty inches ſquare: at ſix inches from the bottom is an aperture, to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three ſquare bars of iron, which traverſe the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces, to examine how the coction goes forward.

On the grate is placed a ſquare earthen pan, ſix or ſeven inches deep; and five or ſix inches leſs, every way, than the perimeter of the furnace. On one ſide hereof is a little aperture, through which to make the trials, placed directly oppoſite to that of the furnaces deſtined for the ſame end.

In this pan are the pieces of glaſs to be placed in the following manner; firſt, the bottom of the pan is covered with three ſtrata, or layers of quicklime, pulverized; thoſe ſtrata being ſeparated by two others, of old broken glaſs: the deſign whereof is to ſecure the painted glaſs from the too intenſe heat of the fire. This done, the glaſſes are laid horizontally on the laſt, or uppermoſt, layer of lime.

The firſt row of glaſs, they cover over with a layer of the ſame powder an inch deep; and over this they lay another range of glaſſes: and thus alternately, till the pan is quite full; taking care that the whole heap always ends with a layer of the lime-powder.

The pan thus prepared, they cover up the furnace with tiles, on a ſquare table of earthen-ware, cloſely luted all round; only having five little apertures, one at each corner, and another in the middle, to ſerve as chimnies.

Things thus diſpoſed, there remains nothing but to give the fire to the work. The fire for the two firſt hours muſt be very moderate; and muſt be increaſed in proportion as the coction advances, for the ſpace of ten or twelve hours; in which time it is uſually completed. At laſt, the

the fire, which at firſt was only of charcoal, is to be of dry wood: ſo that the flame covers the whole pan, and even iſſues out at the chimnies.

During the laſt hours, they make aſſays from time to time, by taking out pieces laid for that purpoſe, through the little aperture of the furnace, and pan, to ſee whether the yellow be perfect, and the other colours in good order. When the annealing is thought ſufficient, they proceed with great haſte to extinguiſh the fire, which otherwiſe would ſoon burn the colours, and break the glaſſes. See PAINTING.

GLASS, *painting on, by means of prints.* See BACK-*painting.*

GLASS, *poliſhing of.* See POLISHING and GRINDING.

GLASS-*porcelain*, the name given by many to a modern invention of imitating the china-ware with glaſs. The method given by M. Reaumur, who was the firſt that carried the attempt to any degree of perfection, is delivered by that gentleman in the Memoirs of the Academy of Sciences of Paris, to this effect. This change of glaſs was firſt taken notice of by Neumann, who, in diſtilling milk in a glaſs retort, obſerved, that the bottom of the veſſel acquired the appearance of porcelain, which he attributes to the fine white earthy matter of the milk forced into the glaſs by heat. Neum. Chem. Works by Dr. Lewis, p. 571.

The mixing of glaſs reduced to powder, with other leſs eaſily vitrifiable ſubſtances for forming a paſte, to be afterwards made into a ſort of a porcelain, has been a contrivance long practiſed, but it is very troubleſome, and the reſult ſubject to many faults; but this new ware is made of glaſs alone, and that with much leſs trouble, and without the reducing it to powder. By this art, veſſels of glaſs are changed into veſſels of a ſort of porcelain, without altering their form, and the meaneſt glaſs made only of ſand, lime, and ſaline aſhes, ſerves as well as the beſt for that purpoſe: our common coarſe green quart-bottles, or the great bell glaſſes with which gardeners cover their melons, &c. being by this means changeable into a beautiful white ſort of porcelain ware; and this is to be done in ſo eaſy a manner, and with ſo ſmall expence, that it requires no more trouble or charge, than that of baking a common veſſel of our coarſe earthen-ware; and for this reaſon the veſſels of this ſort of ware may be afforded extremely cheap.

It is very certain, that all porcelain ware is a ſubſtance in the ſtate of ſemi-vitrification: and in order to bring glaſs, which is a wholly vitrified ſubſtance, into the condition of porcelain, there requires no more than to reduce it to a leſs perfectly vitrified ſtate.

The queſtion which would naturally be ſtarted on this occaſion, is, whether it be poſſible to reduce glaſs to a leſs vitrified ſtate, it having already undergone what is eſteemed the laſt change by fire. But when we conſider, that the maſs of antimony, the vitrifications of many of the metals, as the glaſs of lead, and the counterfeit gems coloured by the metals, are more or leſs eaſily reduced again by chemiſtry to metals, &c. the reducing of ſand, flints, &c. after they are vitrified, at leaſt a little way back toward their native or priſtine ſtate, may appear not wholly impracticable, and the attempts which M. Reaumur made on this occaſion, were what gave him the firſt hints of the glaſs-porcelain; called from his name "Reaumur's porcelain."

The method of making it is this. The glaſs veſſels to be converted into procelain are to be put into a large earthen veſſel, ſuch as the common fine earthen diſhes are baked in, or into ſufficiently large crucibles; the veſſels are to be filled with a mixture of fine white ſand, and of fine gypſum or plaſter-ſtone burnt into what is called plaſter of Paris, and all the interſtices are to be filled up with the ſame powder; ſo that the glaſs veſſels may no where touch either one another, or the ſides of the veſſel they are baked in. The veſſel is to be then covered down and luted, and the fire does the reſt of the work; for this is only to be put into a common potter's furnace, and when it has ſtood there the uſual time for the baking of the other veſſels, it is to be taken out, and the whole contents will be found no longer glaſs, but converted into a white opaque ſubſtance, which is a very elegant porcelain, and has almoſt the properties of that of China. Memoirs Acad. Sciences Par. 1739.

The powder which has ſerved once, will do again as well as freſh, and that for a great many times: nay, it ſeems, ever ſo often. The cauſe of this transformation, ſays Macquer, is probably that the vitriolic acid of the gypſum quits its baſis of calcareous earth, and unites with the alkaline ſalt and ſaline earth of the glaſs, with which it forms a kind of ſalt or ſelenites, differing from the calcareous ſelenites, by the interpoſition of which matter the glaſs acquires the qualities of porcelain. Dr. Lewis, from a variety of experiments on the nature and qualities, and method of producing this porcelain, has deduced the following concluſions: 1. Green glaſs cemented with white ſand received no change in a heat below ignition: in a low red-heat, the change proceeded very ſlowly; but in a ſtrong red-heat, approaching to whiteneſs, the thickeſt pieces of glaſs bottles were thoroughly changed in three hours. 2. The glaſs ſuſtained the following progreſſion of changes. Its ſurface firſt became blue; its tranſparence was diminiſhed, and when held between the light and the eye, it appeared of a yellowiſh hue: afterwards it was changed a little way on both ſides into a white ſubſtance, externally ſtill blueiſh: and as this change advanced ſtill farther and farther within the glaſs, the colour of the vitreous part in the middle approached nearer to yellow: the white coat was of a fine fibrous texture, and the fibres were diſpoſed nearly parallel to one another, and tranſverſe to the thickneſs of the piece: by degrees the glaſs became throughout white and fibrous, the external blueiſhneſs at the ſame time going off, and being ſucceeded by a dull whitiſh or dun colour: by a ſtill longer continuance in the fire, the fibres were changed gradually from the external to the internal part, and converted into grains; and the texture then was not unlike that of common porcelain. The grains, at firſt fine and ſomewhat gloſſy, appeared afterwards larger and duller, and at length the ſubſtance of the glaſs became porous and friable, like a maſs of white ſand ſlightly cohering. 3. Concerning the qualities of the converted glaſs Dr. Lewis obſerves, that the whiteneſs of the internal part was not inferior to that of porcelain, but that its ſurface was the leaſt beautiful; that the thick pieces were quite opaque, and that ſeveral thin pieces were ſemi-tranſparent: that while it remained in a fibrous ſtate, its hardneſs became greater than that of glaſs, or of the common kinds of porcelain; it was capable of ſuſtaining ſudden changes of heat and cold better than any porcelain; and in a moderate white heat, it was fuſible into a ſubſtance not fibrous, but vitreous and ſmooth, like white enamel: that when its texture had been coarſely granulated, it was now much ſofter and unfuſible; and, laſtly, that when ſome coarſely granulated unfuſible pieces which, with the continuance of a moderate heat, would have become porous and friable, were ſuddenly expoſed to an intenſe fire, they were rendered remarkably more compact than before; the ſolidity of ſome of them being ſuperior to that of any other ware. 4. No differences appeared in the internal colour, hardneſs, texture, or the regular ſucceſſion of changes, from the uſe of different cementing ſubſtances;

though in external appearances the differences were conſiderable. All the pieces which had been ſurrounded with charcoal or with ſoot were externally of a deep black colour, which did not diſappear by expoſure to a ſtrong fire during an hour, with free acceſs of air. Coloured clays and ſands communicated different ſhades of a brown colour; and white earths gave whitiſh, greyiſh, or browniſh tinges. White ſand, calcined flints, and gypſum, gave in general the greateſt whiteneſs, and tobacco-pipe clay the greateſt gloſſineſs and brightneſs. Glaſſes compoſed of earths without alkaline ſalt, glaſs of lead, flint-glaſs, crown-glaſs, looking-glaſs plates, a glaſs prepared with calcined flints and a fixed alkaline ſalt, and even green glaſs which had been fuſed together with a ninth part of alkaline ſalt, ſuffered none of the above alterations by cementation. Green bottle-glaſs and common window-glaſs were moſt ſuſceptible of theſe alterations. 6. The changes produced by cementation could not proceed from any abſorption of matter from the cementing ſubſtance; becauſe no increaſe of weight was given, and becauſe the ſame changes were produced upon a piece of glaſs merely by heat, without any cementing ſubſtance. See Com. Phil. Techn. p. 230—255.

Mr. Gregory Watt, in his valuable paper on baſalt (Phil. Tranſ. for 1804, cited by Aikin,) alleges this porcellanous change of glaſs as an illuſtration of his important principle, *viz.* "that bodies whoſe fibres have a natural tendency to a cryſtalline arrangement, or a polarity, when vitrified by a ſufficient heat and cooled haſtily in the vitreous ſtate, are able ſubſequently to return to their natural cryſtalline arrangement of fibre, when expoſed to a heat merely ſufficient to ſoften the texture, though not enough for fuſion. This, in the inſtance of baſalt, he ſhews by the ſingular cryſtallizations formed in the cells of fuſed baſalt, long after it had loſt the liquidity of fuſion. The circumſtance of no material change occurring in the weight of glaſs by this converſion into the fibrous ſtate, ſhews inconteſtably that it cannot be owing either to any thing gained during the proceſs, nor to any material loſs of the alkali; and this is alſo rendered manifeſt by its return to the vitreous ſtate and vitreous qualities when again melted. This too may again be porcellanized in the ſame way, and again be melted into glaſs, and ſo on alternately." See Porcelain.

Glass-*pots*, the veſſels in the glaſs manufacture uſed for melting the glaſs. Thoſe for the white glaſs works are made of a tobacco-pipe clay, brought from the Iſle of Wight, which is firſt well waſhed, then calcined, and afterwards ground to a fine powder in a mill; which being mixt with water, is then trod with the bare feet till it is of a proper conſiſtence, to mould with the hands into the proper ſhape of the veſſels. When theſe are thus made, they are afterwards annealed over the furnace. Thoſe for the green-glaſs work are made of the nonſuch, and another ſort of clay from Staffordſhire; they make theſe ſo large as to hold three or four hundred weight of metal. And beſides theſe, they have a ſmall ſort called piling pots, which they ſet upon the larger, and which contain a finer and more nice metal fit for the niceſt works. Neri.

The clay that is uſed for this purpoſe ſhould be of the pureſt and moſt refractory kind, and well cleanſed from all ſandy, ferruginous, and pyritous matters; and to this it will be proper to add ground crucibles, white ſand, calcined flints duly levigated, or a certain proportion of the ſame clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or expoſed to a great heat, is not abſolutely determined, but depends on the quality of the crude clay, which is more or leſs fat. M. D'Antic, in a memoir on this ſubject, propoſes the following method of aſcertaining it: the burnt and crude clay, being mixed in different proportions, ſhould be formed into cakes, one inch thick, and four inches long and wide. Let theſe cakes be ſlowly dried, and expoſed to a violent heat, till they become as hard and as much contracted as poſſible, and in this ſtate be examined; and the cake, he ſays, which has ſuffered a diminution of its bulk equal only to an eighteenth part, is made of the beſt proportions. He obſerves, in general, that moſt clays require that the proportion of the burnt ſhould be to the freſh as four to five.

It is of great importance that the material of which the pots are made ſhould be carefully ſelected, as they are expoſed to the action of a very fierce fire, and alſo to the ſolvent activity of the glaſs with its powerful fluxes. They ſhould alſo be made very thick and ſtrong, as they are intended to laſt for many months. When finiſhed, they are placed in a warm room in order to diſcharge their moiſture, and any ſmall fiſſures ariſing from the unequal ſhrinking of the clay are cloſed by gently beating with a mallet. They are afterwards gradually heated in a ſmall oven, conſtructed for this purpoſe, and ſlowly brought to a red heat; and after remaining for ſome time in this ſtate, they are removed to the furnace, and fixed down in their places by fire-clay. Here, on account of a further ſhrinking, they remain for a day or two before they are fit for receiving the glaſs materials. Pots of this kind are ſaid to laſt, at an average, about a year.

Glass *Tubes* are of various lengths, diameters, and forms, according to the purpoſes to which they are applied. Theſe are often formed with the lamp and blow-pipe, in the manner deſcribed under the article Lamp-*blowers*. In this way tubes are ſealed hermetically (ſee Hermetical *Seal*), tubes are bent, others are joined, bulbs are annexed to tubes for thermometers, &c., and glaſs is drawn out into threads.

It has been obſerved, that glaſs tubes laid before the fire in an horizontal poſition, and with their extremities ſupported, have had a rotatory motion about their axes; and alſo a progreſſive motion towards the fire, even when their ſupports are inclined from the fire, ſo that the tubes will move a little upwards. See Phil. Tranſ. N° 476. § 1.

When the progreſſive motion of the tube is ſtopped by any obſtacle, its motion about its axis will ſtill continue. When the tubes are placed in a nearly upright poſture leaning to the right hand, the motion will be from eaſt to weſt; but if they lean to the left, the motion will be from weſt to eaſt; when the nearer they are placed to the perfectly upright poſture, the leſs the motion will be either way.

If the tube be placed horizontally on a glaſs plane, the fragment, for inſtance, of coach window-glaſs, inſtead of moving towards the fire, will move from it, and about its axis, in a contrary direction to what it had done before. Nay, it will recede from the fire and move a little upwards, when the plane inclines towards the fire.

Neither the draught of air up the chimney, not attraction or repulſion, are the cauſe of theſe phenomena. It ſeems rather owing to the ſwelling of the tube towards the fire; for allowing ſuch ſwelling, gravity muſt pull the tube down, when ſupported near its extremities horizontally; and a freſh part being expoſed to the fire and ſwelling out again, muſt fall down again, and ſo on ſucceſſively; which will produce a rotatory motion towards the fire.

If the tube be ſupported by two other tubes, and theſe be brought near to each other, and to the centre of the ſupported tube, then its parts hanging over on each ſide, being larger than the part which lies between the ſupporters, will, by their weight, pull downwards, and conſequently force the middle part, reſting upon its two props, upwards: and being leſs advanced towards the fire, as being leſs heated, will, by their oblique ſituation, pull the middle part backwards alſo from the fire, which will cauſe a rotatory regreſſive motion, quite contrary to what the tube had when ſupported near its extremities. And when a ſingle tube lies inclining oppoſite to the fire, either to the right hand or to the left, out of a plane perpendicular to the ſurface of the fire, gravity will not permit the curved part to reſt, but pull it down till it coincides with a plane perpendicular to the horizon; and conſequently, as new curves are generated, new motions will be ſo too; that is, the tube will be made to move about its axis, with this difference, when the tube inclines to the right hand, the motion will be from eaſt to weſt; when to the left hand, from weſt to eaſt. The juſtneſs of this reaſoning is made manifeſt, by bending a wire, and ſupporting it firſt near its extremities, then near its centre on each ſide, afterwards inclining it to the right and to the left; the bending in every caſe repreſenting the curved part of the tube next the fire. This ſolution of the phenomena is rendered the more probable from hence, that when four ſupporters were made uſe of, one at each extremity, and two near the middle, there was no motion at all, either backward or forward. Nor does the increaſe of contact hinder the motion, becauſe the plate of glaſs was ſo broad as to have a much greater contact with the tube, and yet both the rotatory and regreſſive motions were manifeſt.

Theſe experiments ſucceeded beſt with tubes about twenty or twenty-two inches long; the diameter about one-tenth of an inch: and they had in each a pretty ſtrong pin fixed in cork, for an axis to roll with on the ſupporting tubes. Phil. Tranſ. N° 476.

Glass *receivers, how to cement the cracks of.* See Cæment and Receiver.

Glass, *how to take the impreſſion of antique gems in.* See Gem.

The property which glaſs poſſeſſes in common with other ſubſtances of being expanded by heat, and contracted by cold, was long ago obſerved and evinced by Mr. Hook. See Birch's Hiſt of the Royal Society, vol. i. p. 411. See Thermometer.

Glass, *Laws relating to.* No glaſs ſhall be imported into Ireland, other than the manufacture of Great Britain, on pain of forfeiting the ſame, and ſhip, and 10*s.* a pound. 19 G. II. c. 12. If any foreign glaſs ſhall be landed or unſhipped before entry and payment of the duties, or without warrant from the proper officer, the ſame ſhall be forfeited, or its value; and the maſter or other perſon having command of the veſſel, and every other perſon concerned in ſuch landing or unſhipping, ſhall forfeit 100*l.* 17 G. III. c. 39. And by 38 G. III. c. 33. for preventing the fraudulent importation of glaſs, every package containing any plate or plates of glaſs unframed, being *plate, crown,* or *ſheet* glaſs, which ſhall be imported, or brought into this kingdom for exportation, ſhall be marked on the outſide in Roman letters four inches long at leaſt, with the word Glass, on pain of forfeiture, together with the package, and all goods contained in it. The maſter of the veſſel importing ſuch package, ſhall, in reporting his cargo, expreſs every ſuch package of glaſs, on pain of forfeiting the ſame, and alſo 100*l.* Nor ſhall any ſuch package be imported, which ſhall not contain 500 weight, on pain of forfeiture; but not extending to any plate of glaſs 60 inches in length or upwards, on account of the package not being marked. By 43 G. III. c. 69. For every 100 weight of materials, &c. that ſhall be made uſe of in Great Britain for the making of *plate* or *flint glaſs,* or *enamel, ſtained,* or *paſte glaſs,* or *phial glaſs,* ſhall be paid by the maker thereof 1*l.* 12*s* 8*d.*; for every hundred weight of materials uſed in making *ſpread window glaſs,* commonly called *broad glaſs,* 8*s.* 2*d.*; for every hundred weight of materials uſed for making all other *window glaſs* (not being ſpread glaſs), whether flaſhed, or otherwiſe manufactured, commonly called *crown glaſs,* or *German ſheet glaſs,* 1*l.* 4*s.* 6*d.*; for every hundred weight of materials uſed in making *common bottles* (not being phials), and of veſſels uſed in *chemical laboratories,* and of *garden glaſſes,* and of all other veſſels or utenſils made of common bottle metal, 4*s.* 1*d.*; and for every hundred weight of plate glaſs, and of all other glaſs manufactures, which ſhall be imported into Great Britain, the ſame not being flaſks, in which wine or oil is imported, nor foreign green glaſs bottles, nor Iriſh glaſs, or glaſs manufactures imported directly from Ireland, to be paid by the importer before the landing thereof, 2*l.* 2*s.* And any glaſs-maker ſhall take out a licence, for which he ſhall pay 10*l.*, to be renewed annually ten days at leaſt before the end of the year, on the penalty of 50*l.* 24 G. III. c. 41. 43 G. III. c. 69. The place of making glaſs ſhall be entered, before the commencement of manufacture, and all work-houſes, furnaces, pots, annealing arches, &c. &c. on pain of forfeiting 200*l.* 19 G. II. c. 12. 17 G. III. c. 39. 35 G. III. c. 114. Officers may enter and ſurvey, and mark pots; and any perſon counterfeiting or altering ſuch mark, or conniving at its being done, ſhall forfeit 500*l.*; or defacing, or cauſing to be defaced or obliterated ſuch mark, incurs a forfeiture of 200*l.* 35 G. III. c. 114. Notice of beginning to work ſhall be given in writing, on pain of forfeiting 20*l.* 19 G. II. c. 12. And notice of filling every pot ſhall be given twelve hours before the operation is begun, on pain of 50*l.* 19 G. II. c. 12. 17 G. III. c. 39. Annealing arches are to be made of a certain form, and numbered, on pain of forfeiting 100*l.* Annealing arches are to be locked, except at certain times; and breaking ſuch lock, &c. incurs a forfeiture of 200*l.* 35 G. III. c. 114. The ſame act comprehends ſeveral other proviſions, enforced by certain penalties. Bottles are not to be removed till they are weighed, (penalty 100*l.*) which are to be kept ſeparate from thoſe that are unweighed, on pain of forfeiting 50*l.* No phials, &c. are to be made in places entered for making common glaſs bottles, on pain of forfeiting 200*l.* Entry ſhall be made of the glaſs manufactured every month within the bills, and elſewhere every ſix weeks, on pain of 20*l.* The maker, within the bills, ſhall, in four weeks, and elſewhere in ſix weeks after entry, pay off the duties, on pain of double duty. If glaſs, ſhipped for exportation, ſhall be re-landed, it ſhall be forfeited, and every perſon concerned therein ſhall forfeit 100*l.* 17 G. III. c. 39. For the drawbacks on exportation of glaſs, ſee 43 G. III. c. 69. Obſtructing officers in ſecuring the duties incurs a forfeiture of 50*l.* 19 G. II. c. 12. 17 G. III. c. 39. Penalties are appropriated, half to the uſe of the king, and half to him that ſhall ſue.

Glass-*Carrick Point,* in *Geography,* a cape of Ireland, on the eaſtern coaſt of the county of Wexford. N. lat. 52° 35′. W. long. 6° 12′.

Glass-*Caſe,* in *Gardening,* a light ſort of erection formed with glaſs ſaſhes in proper frame-work, moſtly upright in the front part and ends, but ſloping at top from a back wall, or other convenient building, to the fore-part; the front, top, and both ends being of glaſs-work. The ſituation for this purpoſe ſhould face the ſouth, in order to have the full influence of the ſun. Conſtructions of this nature are uſeful for protecting many ſorts of curious tender plants in winter which want it only occaſionally from ſevere froſt, and other ſimilar cauſes.

Buildings of this kind may be conſtructed, occaſionally, either againſt ſome ready-built ſouth wall, which ſerves for the back, all the other parts forward being wood-work and glaſs; or detached in a ſimilar ſituation, ſo as that the whole front may ſtand to the ſouth; the back being framed of brick-work, &c. or of wood double planked; but the former is preferable; the whole being generally ranged lengthways, nearly in an eaſt and weſt direction.

The dimenſions may be from five or ſix, to eight or ten feet in width, by ten, fifteen, or twenty feet in length or more, as may be required; and from ſix or eight, to ten feet high behind, by five or ſix to ſeven or eight in the front, both ends in proportion with the top, ſloping gradually, as juſt noticed, from the back, having an entrance, or door, in front, or at one end. The glaſs-work ſhould be made to ſlide readily backwards and forwards.

Sometimes fire-flues are carried along the back and front internally, proceeding from an external furnace, for occaſional fire-heat in winter, which render them more convenient and uſeful for different purpoſes.

Theſe caſes, as mentioned above, are uſed as preſervatory departments, in which to winter many ſorts of curious exotics of the hardier green-houſe kinds, which only want protection from ſevere cold, as well as many choice kinds of the open ground, which are rather tenderiſh in their minor growth, or any other particular or curious hardy plants, whether flowers, ſhrubs, or young trees, eſpecially the choice evergreen kinds, which require effectual protection from the ravages of rigorous froſts or cutting winds, in winter or early ſpring; and, at the ſame time, in mild open weather, to enjoy the full air by opening the glaſſes; all which, being in pots, can be readily placed in this preſervatory at the approach of ſevere weather, and be thus kept in good condition till ſettled weather in ſpring, &c.; then removed into the full air. In ſummer and autumn, when unoccupied in this way, theſe caſes may be of ſome utility to place ſome curious kinds of tender plants in, when in flower for ſeeding, to guard them from heavy or inceſſant rain, or cold night dews in autumn, which, in many ſorts retard, or ſometimes wholly fruſtrate their production of good ſeed, as in many ſorts of curious tender annuals; particularly the fine double balſams, cock's-combs, tricolors, double ſtramoniums, diamond ficoides, and various others.

They are alſo capable of being uſed in ſpring and the early part of ſummer, as in April, May, and June, as a kind of drawing-frames, for ſome particular ſorts of curious annuals to bring them to a tall growth, ſuch as the large or giant cock's-combs, tricolors, double ſtramoniums, double-ſtriped balſams, egg-plants, &c. the plants being firſt raiſed in hot-beds, under garden-frames, till of twelve or fifteen inches growth, then a hot-bed made in the glaſs-caſe, earthed at top, and the plants in pots, ſingly plunged into the earth of it; the glaſſes, in theſe caſes, ſhould be ſhut cloſe, only a neceſſary admiſſion of freſh air being given every day, by which they run up to a tall ſtature in the beſt perfection of ſtrength for flowering. See *Annual* PLANTS.

Theſe ſorts of glaſs-caſes are alſo ſometimes made uſe of as a kind of appurtenances to hot-houſes, or ſtoves, detached from them, having, as obſerved above, internal flues for fire-heat, when neceſſary, ſerving as preſervatories for many ſorts of exotics, which are tenderer than common green-houſe plants, but do not require the conſtant full heat of the more tender hot-houſe kinds, but only the aſſiſtance of moderate fire-heat in winter, in cold nights, or when very damp, cloudy, foggy-weather and ſevere froſts prevail. They are ſometimes uſed in the buſineſs of forcing different kinds of flowering plants and eſculents, either by means of an internal bark-bed, or flues for fire-heat.

When intended for this purpoſe, it is convenient to have both an internal pit for a bark-bed, and flues for fire-heat, in order to uſe either ſeparately, or ſometimes both, as may be found neceſſary. See HOT-HOUSE.

GLASS-*Faces*, in *Mining*, is a term for the poliſhed ſurfaces, or ſlickenſides, which are found in ſome of the mineral veins in Derbyſhire, ſomething like the poliſhing which is ſeen often on the ſides of faults. See SLICKENSIDE.

GLASS *Iſle*, called alſo *Scalpey*, in *Geography*, one of the Hebrides, near the N.E. extremity of Harris. It is a ſmall, low, round iſland, covered with heath, and indented by the ſea. Near its weſtern extremity are two good natural harbours, and on its eaſt point a light-houſe was erected A. D. 1788. It lies at the entrance of Eaſt Loch Tarbot. N. lat. 57° 50′. W. long. 6° 40′.

GLASS-*Lead*, in *Mining*, according to Mr. Mawe, "Mineralogy of Derbyſhire," p. 105, is an opaque waxy lead-ore found in that county: ſometimes alſo it is tranſparent and cryſtallized, appearing as though it had undergone the action of fire.

GLASS-*Lough*, in *Geography*, a lake of Ireland, in the county of Moneghen, near which is a village of the ſame name, about five miles from the town of Moneghen. The lake contains 120 acres; and a wood, ſpreading over a fine bold hill, hangs down to the water in one deep ſhade, the effect of which is remarkably beautiful. The county around is very fine. Young.

GLASSES are diſtinguiſhed, with regard to their form, uſe, &c. into various kinds, as drinking-glaſſes, optic-glaſſes, looking-glaſſes, burning-glaſſes, &c.

GLASSES, *Drinking*, are ſimple veſſels of common glaſs or cryſtal, uſually made in form of an inverted cone.

Each glaſs conſiſts of three parts, *viz.* the calyx or bowl; the bottom, and the foot; which are all wrought or blown ſeparately.

Nothing can be more dexterous and expeditious than the manner wherein theſe parts are all blown; two of them opened, and all three joined together. An idea is only to be had thereof, by ſeeing them actually at work.

The glaſſes chiefly uſed in England are made of the aſhes of fern; cryſtal glaſſes being leſs frequent in uſe. The exceeding brittleneſs of this commodity, notwithſtanding the eaſy rate of each glaſs, renders the conſumption thereof very conſiderable. For the method of gilding the edges of drinking-glaſſes, ſee GILDING *on Enamel and Glaſs*.

GLASSES, *Metallic*, in *Chemiſtry*, are the oxyds, or ſometimes the ſulphuretted oxyds of the different metals, vitrified by heat.

GLASSES, *Optic*, are thoſe made uſe of to ſtrengthen, improve, or preſerve the ſight. See OPTIC *Glaſſes*.

GLASSES, *Convex*. See CONVEXITY.

GLASSES, *Concave*. See CONCAVE.

GLASS, *Infernal*. See INFERNAL.

GLASSES, *Lenticular*. See LENS.

GLASSES, *Meniſcus*. See MENISCUS, &c.

GLASSES, *Plain*. See PLAIN *Glaſs*.

GLASSES, *Plano-Concave*. See PLANO-CONCAVE.

GLASSES, *Plano-Convex*. See PLANO-CONVEX.

GLASSES, *Teleſcope*. See TELESCOPE.

GLASS, *Object*. See OBJECT-*Glaſs*.

GLASSES, *Eye*. See EYE-*Glaſs*.

GLASS, *Magnifying*. See MAGNIFYING.

GLASS, *Multiplying*. See MULTIPLYING.

GLASSES, *Muſical*. See ARMONICA.

Glass, *Perſpective.* See Perspective.

Glass, *Looking.* See Looking-*Glaſs*, Mirror, and Foliating.

Glass, *Burning.* See Burning-*Glaſs*.

Glass, *Weather.* See Weather-*Glaſs*.

Glass, *Cupping.* See Cupping-*Glaſs*.

Glass, *Window.* See Window and Glass, *ſupra.*

Glass, *Axis of a.* See Axis.

Glass, *Pole of a.* See Pole.

Glass, *Hour.* See Hour-*Glaſs*.

Glass, *Tin.* See Bismuth.

Glass, *Watch.* See Watch.

Glass-*Wort.* See Kali.

Glass-*Wort, Berry-Bearing,* in *Botany.* See Anabasis.

Glass-*Wort, Jointed.* See Salicornia and Kelp.

GLASSHATTEN, or Glasitten, in *Geography*, a town of Hungary, celebrated for its hot-baths, and having near it ſome rich gold mines; 7 miles from Schemnitz.

GLASS-HOUSE Bay, a bay on the E. coaſt of New Holland, betweeen cape Moreton, and the Glaſs-houſes, which are three hills, ſo called by captain Cook in 1770, ſituated in S. lat. 26° 28′.

GLASSHUTTEN, a town of Saxony, near which is a ſilver mine; 8 miles S. of Dreſden.

GLASSIUS, Solomon, in *Biography*, was born in the year 1593, and it is ſuppoſed he was educated at Jena, where he was admitted to the degree of doctor of divinity, and for ſome time filled the theological chair with diſtinguiſhed reputation. He was appointed ſuperintendant of the churches and ſchools in the duchy of Saxe-Gotha, and exerciſed the duties of his function with prudence, equity, and impartiality. He died at Gotha in 1656, and left behind him, as a memorial of his fame and learning, a work publiſhed in quarto in 1623, entitled "Philologia Sacra," which is pronounced by Moſheim an ineſtimable and immortal work, than which none can be more uſeful for the interpretation of Scripture, as it throws much light upon the language and phraſeology of the inſpired writers, He was author, likewiſe, of "Onomatologia Meſſiæ Prophetica;" "Chriſtologia Moſaica et Davidica;" "Exegeſis Evangeliorum et Epiſtolarum," and ſome other pieces. Moreri.

GLASSNEVIN, in *Geography*, a village near Dublin, in Ireland, remarkable for the very extenſive and valuable botanical garden belonging to the Dublin ſociety. See Dublin *Society*.

GLASSY Humour. See Eye and Vitreous.

GLASTONBURY, in *Geography*, a market town in the hundred of Glaſton, and county of Somerſet, England, is ſituated on the great road from Wells to Exeter. The ſcite occupied by it was originally called Ynyſwytryn, or the Glaſs Iſland, and in Latin Avalonia.

A town is ſaid to have been built here, and largely endowed by king Ina about the year 708: in the next century it was laid waſte by the Danes, and rebuilt by king Edmund, who granted it many additional privileges. In 1184 it was deſtroyed by fire, and was again reſtored by the munificence of Henry II. The chief celebrity attached to the town was derived from its abbey; which, during ſix centuries, ſurpaſſed in authority and revenues every other in England, excepting that of Weſtminſter. The abbots enjoyed a ſtate of regal ſplendour, with an income of nearly 40,000*l* per annum, had the title of lords, and ſat with the barons in parliament. The abbey and its offices occupied an area of land of nearly ſixty acres within the walls.

The laſt abbot, Richard Whiting, who was the ſixtieth in ſucceſſion, refuſing to ſurrender his abbey to king Henry VIII. was, with two of his monks, drawn on a hurdle to the Torr, near the town, and there hanged: the abbot's head was ſet on the gate of the abbey, and his quarters were ſent to Bath, Wells, Bridgewater, and Ilcheſter.

It being traditionally recorded, that this was the burial place of king Arthur, Henry II. ordered a ſearch to be made, when a leaden croſs was diſcovered with a Latin inſcription in rude characters, thus tranſlated; "Here lies the famous king Arthur, buried in the iſle of Avalon." Beneath was found a coffin hollowed out of the ſolid rock, wherein were the bones of a human body, ſuppoſed to be thoſe of Arthur; which were then depoſited in the church under a monument. Scarcely any veſtige remains of theſe extenſive buildings, except ſome ruins of the church, part of a chapel dedicated to Joſeph of Arimathea, and the abbot's kitchen, which ſeems to be of a more recent ſtructure than the other offices.

Among the religious relics with which the town and its environs abound, the moſt conſpicuous is the Torr, or St. Michael's Tower (on which abbot Whiting was executed,) ſtanding on an eminence eaſt of the town, where was formerly a ſmall oratory, dedicated to St. Michael the archangel.

The town of Glaſtonbury conſiſts of two principal ſtreets, and is divided into two pariſhes, St. John's and St. Benedict's. It was formerly a parliamentary borough, but was disfranchiſed on the confiſcation of the abbey in 1539. A charter of incorporation was granted by queen Anne, by which the civil government was veſted in a mayor, a juſtice, eight aldermen, and ſixteen burgeſſes. The principal buildings are the two pariſh churches, two meeting-houſes, two alms-houſes, and a free ſchool. The George, a reſpectable inn, was anciently an hoſpital for the accommodation of pilgrims reſorting to the ſhrine of St. Joſeph. In the centre of the town was formerly a large ſtone croſs, originally appropriated to ſhelter perſons who attended the market. It was taken down about five years ago: but a plate and deſcription are preſerved in the firſt volume of the Architectural Antiquities of Great Britain. Glaſtonbury is 130 miles diſtant from London; has a market on Tueſdays, and four annual fairs: the population return, in 1801, was 410 houſes, and 2035 inhabitants, of whom only 104 were employed in trade, which is chiefly that of manufacturing worſted ſtockings.

South-weſt of the town is Wearyall hill, ſo called from a tradition that St. Joſeph and his companions, weary with their journey, reſted here; and that St. Joſeph ſtuck his hawthorn ſtaff in the earth; it took root, and conſtantly budded on Chriſtmas day. This famous thorn had two trunks, of which one was deſtroyed in queen Elizabeth's reign, the other in the great rebellion: but there are trees, originally from the old ſtock, ſtill growing in the gardens of Glaſtonbury, and in various other parts of the kingdom. Collinſon's Hiſt. Somerſetſhire, 3 vols. 4to. Maton's Weſtern Counties, 2 vols. 8vo.

Glastonbury, a townſhip of America, in the county of Bennington, and ſtate of Vermont; having only 48 inhabitants.—Alſo, a handſome little town in Hartford county, Connecticut, ſituated on the E. ſide of Connecticut river, oppoſite to Weathersfield; containing 2718 inhabitants.

Glastonbury *Thorn*, in *Botany.* See Mespilus.

GLASTUM, from the German word *Glaſt*, an old name for Woad; (ſee Isatis.) Hence ſeveral plants have the ſpecific name of *glaſtifolia*, on account of the ſimilitude of their leaves to that herb.

GLATT, in *Geography*, a river of Germany, which runs into the Neckar, 2 miles N. from Sultz in Wurtemberg.

GLATT, or *Glatten*, a town of Germany, in the county of Fugger; 4 miles E. of Dornſtetten.

GLATT, a river of Switzerland, which runs into the Rhine; 2 miles below Egliſau.

GLATTEN, a mountain of Switzerland; 10 miles S. S. W. of Glaris.

GLATZ, a principality of Sileſia, bordering on Bohemia, and ſurrounded by mountains. The internal territory is mountainous, interſected with vallies, meadows, corn-fields, woodlands and ſmall rivers. It produces wheat, generally ſufficient for its inhabitants, and has paſture for a great number of cattle. It contains quarries of mill-ſtones, free-ſtone, and marble; as well as a great variety of precious ſtones. It has alſo mines of coal, copper, and ſilver; with ſeveral mineral ſprings. From 1561 to 1742, Glatz was annexed to the crown of Bohemia; in 1742 it was ceded by the empreſs Maria Thereſa to Frederick II. king of Pruſſia, and his heirs. It forms one circle, divided into ſix diſtricts.

GLATZ, the capital of the principality above-mentioned, is ſituated on the Neiſſe, and built on the ſide of a mountain, having upon its ſummit a ſtrong caſtle. The town contains about 400 houſes within the walls, and as many in four fauxbourgs. It is a place of conſiderable trade. It has been frequently pillaged and burnt; 54 miles E. of Breſlau. N. lat. 50° 16′. E. long. 16° 26′.

GLATZ *Kogel*, a mountain of Auſtria; 12 miles S. of Steyr.

GLAVACIA, a town of Walachia; 35 miles W. of Buchareſt.

GLAUBER, JOHN RODOLPH, in *Biography*, a celebrated chemiſt of Amſterdam, who was eſteemed the Paracelſus of his age, was born in Germany in the beginning of the ſixteenth century. He travelled much in the purſuit of chemical knowledge, and collected many ſecret proceſſes; and his experiments contributed to throw much light on the compoſition and analyſis of the metals, inflammable ſubſtances, and ſalts. In fact he paſſed the greater part of his life in the laboratory. He did not always ſee the proper application of his own experiments, and vainly fancied that he had diſcovered the panacea, and the philoſopher's ſtone, which were at that time objects of purſuit: and the diſappointment of many perſons, who had been ſeduced by his promiſes, contributed to bring the art of chemiſtry into contempt. His theory is full of obſcurity; but his practice has perhaps been miſrepreſented by thoſe who liſtened to his vain and pompous pretenſions; and who accuſe him of a diſhonourable traffick, in firſt ſelling his ſecrets to chemiſts at an enormous price, of again diſpoſing of them to other perſons, and laſtly, of making them public in order to extend his reputation. Glauber publiſhed about twenty treatiſes; in ſome of which he appears in the character of phyſician, in others in that of an adept or metallurgiſt; in the latter he moſt particularly excelled. However, it would be unjuſt not to give him the praiſe of acuteneſs of mind, of facility and addreſs in the proſecution of his experiments, and of extenſive chemical knowledge. He was the inventor of a ſalt, which to this day retains his name in the ſhops of our apothecaries. The works of Glauber have appeared in different languages; the majority of editions are in German, ſome in Latin, and others in French. A collection of the whole in Latin was publiſhed at Frankfort in 1658, in 8vo. and again 1659 in 4to. An Engliſh tranſlation was publiſhed by Chriſtopher Pack, London, 1689, in folio. Eloy. Dict. Hiſt.

GLAUBER *Salt, native* or *natural*, in *Mineralogy*, the ſulphat of ſoda of chemiſts, was diſcovered by baron Born in the ſalt mines of Upper Auſtria; after which Monnet, Volta, Suckow, Gmelin, Breiſlak, Pallas, and others have added to the liſt of the localities of this ſaline ſubſtance, which is more frequently found in a native ſtate than has been ſuppoſed by ſome writers. It generally occurs as mealy eﬄoreſcence; ſometimes maſſive, ſeldom ſtalactitical or cryſtallized: in which latter caſe the cryſtals are deſcribed as acicular and as ſix-ſided priſms, more or leſs flatly acuminated by three planes, ſet on the lateral edges, or ſometimes on the lateral planes: they are ſhining: their internal luſtre is vitreous. Fracture of the cryſtals ſmall conchoidal. It varies from tranſparent to opaque according to its freſhneſs. It is brittle. Its taſte is a mixture of ſalt and bitter. Beſides in the above forms, it occurs alſo, and moſt frequently, diſſolved in certain mineral waters, in the neighbourhood of ſalt mines and ſalt lakes, where alſo the eﬄoreſcence is moſtly found on mooriſh ground, ſand ſtone, marle ſlate, and new walls. For the chemical character of this ſalt, ſee SODA, *Sulphat of.*

Brongniart has given the moſt complete liſt of the localities of Glauber ſalt. In ſolution it occurs in the waters of ſeveral lakes of Auſtria and Lower Hungary, eſpecially in that of Neuſiedel, between the counties of Oedenburg and Wieſelburg. It is met with in Switzerland; in Spain, round a ſource in the neighbourhood of Aranjuez, and near Vacia-Madrid, as eﬄoreſcence, at the bottom of a ravine: the ſource which iſſues from the ravine contains a great proportion of this ſalt. Alſo the water of the Tagus is ſaid to hold it in ſolution. In France it has been found near Grenoble. The ſteep ſides of the Solfatara of Pouzzole yield this ſalt, in one place, on the north ſide. It is common in the lakes of Siberia; and it has been obſerved that the bottom of the lake Guniſkoi, between Toïon and Ilynſkoy, is covered with a cruſt of Glauber ſalt as ſoon as the temperature is below the freezing point. Pallas tells us that the apothecaries of Orenburg annually collect a quantity of this ſalt, which is depoſited in autumn at the bottom of a lake between the Tobol and Mioes. It is alſo found in a lake near Gourief; in another between Utoiſka and Miniuſkaïa, in the neighbourhood of Eniſſey; likewiſe at the foot and in the middle of the chains of the Ural mountains, near Tſheliabinſk: in the laſt of theſe places, the ſalt iſſues in the ſpring ſeaſon out of the earth in the form of eﬄoreſcence or froth. The clayey ſoil of that neighbourhood does not contain any Glauber ſalt; whence this is ſuppoſed to be formed, in the ſame manner as ſalt-petre is, at the ſurface of the earth, and by the action of the atmoſphere. Laſtly, this ſalt is alſo obtained from the alum-ſlate of Duttweiler, near Saarbrück, in the department of la Sarre, and from the aluminiferous waters of Freyenwalde, in Brandenburg.

GLAUBER's *Salt*, in *Chemiſtry* and *Materia Medica*. See *Sulphat of* SODA.

GLAUBER's *Spirit of Marine Salt*. See MURIATIC *Acid*.

GLAUBER's *Spirit of Nitre*. See NITRIC *Acid*.

GLAUBERITE, a lately diſcovered mineral, belonging to the claſs of ſalts, and of which M. Brongniart has given the deſcription and analyſis. This ſubſtance (called glauberite by its diſcoverer, both in honour of the well-known Glauber, and on account of its containing a conſiderable quantity of the ſalt which bears the name of that alchemiſt) was found among pieces of rock-ſalt brought from Ocana in New Caſtile, in cryſtals reſembling thoſe of thumſtone, or axinite. They were (chiefly on account of their mode of occurring) miſtaken in Spain for gyps-cryſtals.

The form of theſe ſecondary cryſtals, is that of an oblique very ſhort priſm with rhomboidal baſe. The planes of the baſe are generally ſmooth and ſhining; the lateral planes ſtriated parallel to the edges of the baſe. Cleavage double, the one parallel to the baſes, the other leſs diſtinct and parallel to the edges of the baſe; in all other directions the fracture is vitreous. Hence the primitive form is an oblique priſm with rhomboidal baſe, the obtuſe angles of which correſpond with the obtuſe angles of the ſecondary priſm. The cryſtals are from topaze yellow to nearly colourleſs; they are tranſparent, and, provided they are kept dry, preſerve their tranſparency and ſolidity though expoſed to the air. Their hardneſs ſurpaſſes that of ſulphat, but is inferior to that of carbonat of lime.

Expoſed to an intenſe heat, the glauberite decrepitates and melts into a white enamel. Immerſed in water, its ſurface is covered by a milk-white cruſt, which penetrates deeper and deeper, till the whole cryſtal is white and opaque throughout: taken out of the water and dried, the white cruſt crumbles into duſt, leaving the nucleus, if there be any remaining, unaltered and perfectly tranſparent. Specific gravity about 2.73.

From M. Brongniart's experiments it appears, that glauberite is eſſentially compoſed of anhydrous ſulphat of lime and of ſulphat of ſoda, equally anhydrous. 2. That theſe two ſalts exiſt in this ſubſtance nearly in the following proportions:

Anhydrous ſulphat of lime - - - -	0.49
Anhydrous ſulphat of ſoda - - - -	0.51
	100

A trace of water, indicated by the calcination, is not brought into account, as little as the accidental admixture of a ſcarcely perceptible quantity of iron, to which the yellowiſh colour of this ſubſtance appears to be owing.

Mr. B. adds the following obſervations: the above-mentioned pieces of ſalt from Ocana, which contain this ſubſtance, have generally ſome clay adhering, which penetrates into the ſtriæ of the ſurfaces, but ſeldom into the ſubſtance of the glauberite.

The efflоreſcence on glauberite, when moiſtened, and the property this ſalt poſſeſſes of becoming opaque in water, proceed from this, that the water, by diſſolving the ſulphat of ſoda, transforms the ſulphat of lime into a ſpongy ſubſtance, and thus produces a phenomenon which is the reverſe of that exhibited by the hydrophane.

The exiſtence of native ſulphat of ſoda, or Glauber ſalt, is well known to mineralogiſts, and, indeed, it has been met with in the neighbourhood of beds of rock-ſalt; but this was only as ſolution in the water of ſalt-ſprings, or as efflоreſcence near ſalt-mines: in a ſolid and cryſtallized ſtate, entirely deſtitute of water of cryſtallization, and intimately united with ſelenite, it had never before been obſerved. Even the anhydrous ſulphat of ſoda was almoſt entirely unknown, till Berthier proved that it conſtitutes nearly the fifth part of thoſe hard ſcales found at the bottom of the pans in which the ſea-ſalt is obtained by evaporation.

It remains to be aſcertained, under which circumſtances the rock-ſalt occurs which contains the glauberite, and particularly in what relation this latter ſtands to it, and whether it occur in the rents or on the ſurface of the beds. See Journal des Mines for 1808.

Haüy places the glauberite ſeparately at the end of the *ſubſtances acidifères;* and it appears to this mineralogiſt, that the integrant molecules of the two ſalts of which it is compoſed exiſt together in the glauberite. He refers, for an analogous combination, to Leblanc's experiments, according to which a ſolution of ſulphat of copper and ſulphat of iron mixed, yielded cryſtals compoſed of theſe two ſubſtances, while their primitive form proved to be that of the latter, which had impreſſed on this mixture the character of its particular cryſtallization. The queſtion, therefore, is, whether the glauberite be in a ſimilar caſe. Its form has, indeed, nothing in common with that of the anhydrous ſulphat of lime; but we are totally unacquainted with the cryſtalline form of the anhydrous ſulphat of ſoda. But even if it ſhould be found that in this caſe the two molecules combine in ſuch a manner as to produce a third of a different form from either, this circumſtance could, according to Haüy's opinion, not be adduced as an objection againſt the theory of cryſtallization, and muſt be conſidered as a problem, the ſolution of which is more intereſting to the chemiſt than to the mineralogiſt.

GLAUBOTTE, in *Geography*, a town of Pruſſia, in Natangen; 14 miles S.E. of Bartenſtein.

GLAUCEDO, in *Surgery*. See GLAUCOMA.

GLAUCHA, in *Geography*, a town of Saxony, in the lordſhip of Schonburg, on the Mulda, containing about 600 houſes; the inhabitants are employed in the manufacture of ſtuffs; 46 miles W. of Dreſden. N. lat. 50° 45′. E. long. 12° 25′.

GLAUCHE, a town of Germany, in the duchy of Magdeburg, adjoining to the town of Halle, but governed by its own magiſtrates; in which are four ſeminaries, where the languages, theology, mathematics, muſic, &c. are taught by 120 preceptors.

GLAUCION, in *Ornithology*, a ſpecies of *Anas*, the grey-headed duck. See DUCK.

GLAUCIUM, in *Botany*, is ſo named from its glaucous, or ſea-green, colour. Whether the plant intended by Pliny be the Yellow Horned Poppy, according to the opinion generally received, or any maritime ſpecies of *Euphorbia*, ſeems a point not eaſily determined. Γλαυκιον of Dioſcorides appears to be the juice of the firſt-mentioned in its wild ſtate, though he compares it to his μηκων κερατιτις, (which is evidently the Yellow Horned Poppy itſelf,) ſaying the plant which yields the γλαυκιον, and grows at Jeruſalem, has almoſt the leaves of the μηκων κερατιτις, but thicker, and ſpread on the ground, ſtrong ſmelling, and more bitter, yielding plenty of ſaffron-coloured juice. Poſſibly this may refer to one of our other ſpecies of *Glaucium*, if not to the common wild *luteum*. Moſt commentators have taken *Argemone mexicana* for the plant of Dioſcorides; but that is a tropical production, unknown in Europe, as we preſume, previous to the diſcovery of America, though now naturalized in the Eaſt Indies; ſee ECHTRUS. Neither does the above deſcription ſuit this plant, for its leaves are much thinner than thoſe of the Horned Poppy, and their juice pale yellow; nor are they ſpread on the ground. Matthiolus ſeems to take the drug Gamboge for γλαυκιον, but this does not at all help us, as to the botanical queſtion, nor has it any probability in its favour.—Tourn. Inſt. 254. t. 130. Sm. Fl. Brit. 563. Prod. Fl. Græc. v. 1. 357. Juſſ. 236. Gærtn. t. 115. (Chelidonium; Linn. Gen. 262. Schreb. 350. Willd. Sp. Pl. v. 2. 1141. Lamarck. Illuſtr. t. 450. f. 2. Mart. Mill. Dict. v. 2.)—Claſs and order, *Polyandria Monogynia*. Nat. Ord. *Rhœadeæ*, Linn. *Papaveraceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of two ovate, concave, bluntiſh, deciduous leaves, often tipped with a point near the ſummit. *Cor.* Petals four, large, roundiſh, ſlightly concave, nearly equal, with a ſhining ſpot near the baſe. *Stam.* Filaments numerous, ſhorter than the corolla, flat, incurved, rather dilated upwards; anthers erect, roundiſh, of two lobes. *Piſt.* Germen nearly cylindrical, curved, longer than the ſtamens; ſtyle none; ſtigma with two or three lobes, downy. *Peric.* Pod linear, curved, very long, of two or three cells, and as many concave valves. *Seeds* numerous, globular, dotted. *Receptacle* linear, ſpongy, parallel to the valves, its ſurface cellular to receive the ſeeds.

Eſſ. Ch. Calyx of two leaves. Petals four. Pod ſuperior, linear, of two or three cells and two or three valves. Seeds numerous, dotted.

Obſ. This genus is very naturally diſtinguiſhed from *Chelidonium* by its habit, and eſſentially characterized by having more than one cell in its pod, and no creſt to its ſeeds.

1. G. *luteum.* Yellow Horned-Poppy. Scop. Carn. v. 1. 369. Gærtn. v. 2 166. (G. flore luteo; Tourn. Inſt. 254. Chelidonium glaucium; Linn. Sp. Pl. 724. Engl. Bot. t. 8. Papaver cornutum, flore luteo; Ger. em. 367.)—Stem ſmooth. Stem-leaves rounded, waved. Pods roughiſh with minute tubercles. Flowers ſtalked.—Native of ſandy ſea-ſhores throughout Europe, flowering in ſummer and autumn. *Root* perennial, tap-ſhaped. Whole *herb* roughiſh and very glaucous. *Stems* three feet high, ſpreading, branched, leafy, ſmooth. Radical *leaves* numerous, pinnatifid in a lyrate form; the reſt rounded, wavy or ſinuated, alternate, ſeſſile, claſping the ſtem. *Flowers* ſolitary, on axillary or terminal ſtalks, two inches broad, of a full ſhining yellow. Their calyx is hiſpid and deciduous, and the petals laſt but one day. The *pods* are often near a foot long, cylindrical, but compreſſed.

2. G. *fulvum.* Orange Horned-Poppy. Sm. Exot. Bot. v. 1. 11. t. 7. (G. glabrum, flore phœniceo; Tourn. Inſt. 254? Chelidonium corniculatum; Donn. Cant. ed. 5. 131.)—Stem ſmooth. Stem-leaves rounded, waved. Pods rough. Flowers nearly ſeſſile.—Suppoſed to be a native of the ſouth of Europe, but we know it as a garden plant only. This differs from the former in the rather more blue caſt of its herbage, nearly or quite ſeſſile *flowers*, and ſmaller petals of a rich tawny orange-colour. We have thought the *root* annual, but we find it will ſurvive a mild winter, about as well as the firſt ſpecies, which indeed is often killed, and never lives many years, at leaſt in a garden. The G. *fulvum*, whether a diſtinct ſpecies or only a permanent variety, propagates itſelf by ſeed and remains unaltered. Its flowers, contraſted with the leaves, have a ſingularly elegant effect. Their petals fall, in hot weather, before noon, but in the autumn will endure till the next morning, or longer, which is alſo the caſe when they are gathered and placed in a room. —If our quotation of Tournefort be right, our plant is figured in Lobel's Icones 271, f. 2, but not happily.

3. G. *rubrum.* Red Horned-Poppy. Sm. Prodr. Fl. Græc. v. 1. 357. (G. orientale, flore magno rubro; Tourn. Cor. 18.)—Stem hairy. Stem-leaves pinnatifid, cut. Pod ſlightly hairy.—Gathered by Dr. Sibthorp by the wayſide between Smyrna and Burſa, as well as in the iſle of Rhodes. The *root* ſeems to be annual. *Stems* ſpreading, or nearly proſtrate, clothed with ſoft expanded hairs. *Stem-leaves* elongated, and deeply pinnatifid, by which it eſſentially differs from both the preceding, as it does from the following in the ſoft hairs, inſtead of rigid briſtles, which clothe the pods and ſtem. The *flowers* are ſtalked, with obovate petals, narrower and flatter than in either of the former, of a tawny red, with a violet ſpot on the claw. Lobel's Papaver corniculatum phœniceum alterum, Ic. 271. f. 2, agrees with this rather than with the laſt in its petals, and ſomewhat in its leaves; but if Tournefort be correct, it cannot be deſigned for the preſent ſpecies, which he gives in his Corolla as different from all he had previouſly enumerated, including Lobel's plant.

4. G. *phœniceum.* Scarlet Horned-Poppy. Sm. Fl. Brit. 964. Prodr. Fl. Græc. v. 1. 357. Engl. Bot. t. 1433. (G. hirſutum, flore phœniceo; Tourn. Inſt. 254. G. corniculatum; Curt. Lond. faſc. 6. t. 32. Chelidonium corniculatum; Linn. Sp. Pl. 724. Papaver cornutum, flore phœniceo; Lob. Ic. 271. f. 1.)—Found in cultivated fields in the ſouth of Europe; a doubtful native of England, though eaſily naturalized in a garden. It is annual, flowering in ſummer and autumn, and grows rather more erect and buſhy than the laſt, from which it differs in the rigid cloſe-preſſed briſtles which clothe the *pods.* The *petals* moreover are larger, rounder, and of a rich ſcarlet, though each marked with a violet ſpot like the laſt; and the ſpreading briſtles on the *ſtem* are very different from the ſoft hairs of that ſpecies.

5. G. *violaceum.* Violet Horned-Poppy. Sm. Fl. Brit. 565. Prodr. Fl. Græc. v. 1. 358. (G. flore violaceo; Tourn. Inſt. 254. Chelidonium hybridum; Linn. Sp. Pl. 724. Engl. Bot. t. 201.)—Leaves bipinnatifid, linear. Pods of three valves.—Native of fields in the ſouth of Europe; rare in England. The *root* is annual. *Stem* branched, upright and buſhy, a foot high, occaſionally ſmooth, or clothed with ſpreading hairs, as is likewiſe the caſe with the *leaves*, which are twice, or even thrice, pinnatifid; their ſegments linear and acute. *Flowers* rather large, of a fine violet colour; their *pods* of three valves, though ſcarcely three-celled, except in an early ſtage of their formation.

Glaucium, in *Ornithology*, a name given by Briſſon to the Anas *Fuligula* or tufted duck. See Duck; and alſo to the Anas *Marila*, or ſcaup-duck. See Duck.

GLAUCOMA, or Glaucosis, a term, in *Surgery*, importing, with the Greeks, according to Mr. Samuel Sharp, what the Latin writers underſtand by *ſuffuſio*, and what we call a *cataract.* This diſeaſe, as we have elſewhere explained, is an opacity of the cryſtalline lens. (See Cataract.) Mâitre-Jean, St. Yves, and other oculiſts, however, think, that glaucoma is a cataract complicated with the gutta ſerena, or an inſenſible ſtate of the retina and optic nerve. (See Gutta Serena.) The word is derived from γλαυκος, *blue*, the pupil frequently having that colour. Some writers have regarded glaucoma as a defect of ſight, originating from an opaque, or otherwiſe morbid ſtate of the vitreous humour. Such a caſe is uncommon; but were an opacity of this kind to impede viſion, an endeavour ſhould be made to diſperſe it with ſmall doſes of calomel, and by expoſing the eye to the vapour of ether. In the event of theſe means failing, the opacity might be broken and diſturbed with a couching-needle. The fungus hæmatodes of the eye muſt be diſcriminated. See Fungus.

GLAUCOPIS, in *Ornithology*, a genus of the order Picæ. The bill is incurvate and arched; the lower mandible ſhorter, and caruncculate beneath at the baſe; noſtrils depreſſed, and half-covered with a ſomewhat cartilaginous membrane; tongue ſubcartilaginous, divided at the end, and ciliated; legs formed for walking; toes three before and one behind.

The only ſpecies of this extraordinary genus at preſent known, is the wattle bird of Dr. Forſter, deſcribed in the Voyages of Captain Cook, and which appears, from the later obſervations of other naturaliſts, to be excluſively confined to the Auſtralaſian regions. Its ſize is equal to that of the jay, the length from the bill to the tail fifteen inches. The bill remarkably ſtrong, an inch and a quarter in length, and of a black colour. The noſtrils are ſituated in a hollow at the baſe of the bill, and are half-covered by a membranous cartilage which falls over as a cover. Its wattles are pendent from the baſe of the lower mandible on each ſide, and in texture reſemble the wattle of the common cock; the colour at firſt blue, and afterwards fine orange. The irides fine blue. From the forehead to the eye the colour is deep black: the other parts of the plumage dark aſh-colour. The tail long, wedge-ſhaped, and compoſed of twelve feathers. Legs long, and the hind claw much longer than the reſt.

This bird inhabits New Zealand, where it ſubſiſts on berries and inſects, and is ſometimes ſeen perched on trees, though rarely, as it is uſually ſeen walking on the ground: its note is a kind of whiſtling or rather murmuring noiſe; and the fleſh ſavoury and delicate.

GLAUCUM, in *Ancient Geography*, a promontory of the Libyan nome, on the confines of Marmarica and Egypt, upon which was a town of the ſame name. Ptolemy.

GLAUCUS, a river of the Peloponneſus, in Achaia, near Patras. Pauſanias.—Alſo, a river of Aſia Minor, in Lycia, having its mouth N. E. of the town of Telmiſſus, in the gulf of Glaucus.—Alſo, a river of Aſia, in the territory of Colchis, where it diſcharges itſelf into the Phaſis. Pliny.—Alſo, a gulf of Aſia Minor, in a direction from N. W. to S. W. More anciently this gulf was denominated the gulf of Telmiſſus, from the name of the town, ſituated near its termination in the eaſtern part of it.

Glaucus, in *Ichthyology*, a ſpecies of *Chætodon*; which ſee.—Alſo, a ſpecies of *Scomber*.—Alſo, a ſpecies of *Falco*, which ſee reſpectively.

GLAUX, in *Botany*, ſo called by Pliny, and Γλαυξ by Dioſcorides, is of uncertain derivation, though ſome have deduced its name from γαλα, *milk*. Moſt probably the word *glaucous* is ſimilarly derived, as it conveys the idea of a milky green colour.—Linn. Gen. 114. Schreb. 159. Tourn. 60. Willd. Sp. Pl. v. 1. 1210. Sm. Fl. Brit. 268. Mart. Mill. Dict. v. 2. Lamarck Dict. v. 2. 722. Juſſ. 333.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Salicariæ*, Juſſ.

Gen. Ch. *Cal.* none: unleſs the corolla be conſidered as ſuch. *Cor.* of one petal, five-cleft, bell-ſhaped, erect, permanent, with obtuſe revolute lobes. *Stam.* Filaments five, awl-ſhaped, erect, the length of the corolla; anthers roundiſh. *Piſt.* Germen ovate; ſtyle filiform, as long as the ſtamens; ſtigma capitate. *Peric.* Capſule globoſe, pointed, of one cell, with five valves. *Seeds* five; roundiſh; receptacle very large, globoſe, hollowed for the ſeeds.

Eſſ. Ch. Calyx of one leaf. Corolla none. Capſule of one cell, with five valves and five ſeeds.

1. G. *maritima*. Black Salt-wort. Linn Sp. Pl. 301. Engl. Bot. t. 13. This is the only ſpecies known, being very frequent in ſalt-marſhes throughout Europe, and flowering in ſummer. The *root* is perennial and creeping. Stem about four inches high, erect, ſomewhat branched, thickly covered with ovate, ſeſſile *leaves*, and fleſh-coloured, purpliſh, or whitiſh flowers. Dr. Withering has remarked that cows eat this herb, and that it is uſed for a pickle, being found every where from Lapland to the Archipelago. The deſcription in Dioſcorides, book 4. chap. 141. is ſo exact that it is impoſſible to be miſtaken; yet we do not find this plant in the Prodromus Floræ Græcæ, becauſe Dr. Sibthorp did not himſelf obſerve it in his journey.

GLAZIC, in *Geography*, a ſmall iſland in the Engliſh Channel, near the coaſt of France. N. lat. 47 26. W. long. 2 56.

GLAZIER, an artificer or dealer in glaſs.

GLAZING. The Roman method of glazing ſome of their urns might give our workmen a hint toward a method greatly ſuperior to any thing now in practice for the glazing of earthen-ware. There is a ſort of red urns found in Yorkſhire, which are, inſtead of glazing, covered all over inſide and out with a fine coral-coloured varniſh, that gives them a beauty, which no earthen-ware of our times can attain; and is not only far more durable than our way of doing it with lead, which is apt to crack and fly, both with wet and with heat, but far more ſafe and wholeſome; and being well known to be a vapourable metal, and its fumes very noxious, there is great reaſon to ſuſpect that it muſt be unwholeſome when brought to the fire. This ancient glazing ſeems to have been done either by the bruſh, or elſe by dipping, for both the inſide and outſide are varniſhed with equal regularity; and ſomething may be gueſſed at as to the materials they uſed in it, from what Pliny has left us. This author occaſionally obſerves, that ſuch earthen-ware as was painted with bitumen never loſt its beauty; and afterwards, that it was a cuſtom to cover over whole ſtatues with this ſort of glazing, which he obſerves did not only make a ſmooth coat, but ſunk into the matter of the ſtone or earth, and therefore this could not be likely to crack and fly off like our lead-coats on plates, &c. which is merely a cruſt laid over them. Hook's Philoſ. Collect. p. 89.

A common glazing for any kind of earthen-ware may be made of white ſand forty pounds, of red-lead twenty pounds, of pearl-aſhes twenty pounds, and of common ſalt twelve pounds. Powder the ſand by grinding it, and then add it to the other ingredients and grind them together: after which calcine them for ſome time with a moderate heat, and when the mixture is cold, pound it to powder; and when wanted for uſe, temper it with water. The proportion of theſe ingredients may be occaſionally varied. We may obſerve, in general, that lead ought to be excluded from the compoſition of glazings, and other fluxes ſubſtituted in its ſtead. See Colica *Dammoniorum*.

A tranſparent glazing may be prepared, without lead, by calcining forty pounds of white ſand, twenty-five pounds of pearl-aſhes, and fifteen pounds of common ſalt; and proceeding as before: and a more perfect tranſparent glazing may be made of ſand forty pounds, of wood-aſhes perfectly burnt, fifty pounds, of pearl-aſhes ten pounds, and of common ſalt twelve pounds. The following recipes are taken, for the moſt part, from Kunckel, who ſays that they are the true glazings uſed at Delft, and other Dutch manufactories.

Glazing, *Black*, is made of eight parts of red-lead, iron filings three, copper-aſhes three, and zaffre two meaſures. This, when melted, will make a brown black; and if you want it blacker, add more zaffer to it.

Glazing, *Blue*, is thus prepared: take lead-aſhes, or red-lead, one pound, clear ſand, or powdered flints, two pounds, common ſalt two pounds, white calcined tartar one pound, Venice or other glaſs half a pound, zaffer half a pound: mix them well together, and melt them for ſeveral times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glaſs furnace for a day or two.

Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of zaffer, and a quarter of a pound of powdered flints, which are to be fuſed and managed as in the laſt recipe. Or, take two pounds of calcined lead and tin, add five pounds of common ſalt, five pounds of powdered flints, and of zaffer, tartar, and Venetian glaſs, each one pound. Calcine and fuſe the mixture as before.

Or, again, take of red-lead one part, of ſand three parts, and of zaffer one part. For a violet blue glazing, take four ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganeſe.

Glazing, *Brown*, is made of red-lead and flints, of each fourteen parts, and of manganeſe two parts, fuſed: or, of red-lead twelve parts, and manganeſe one part, fuſed. A brown glazing, to be laid on a white ground, may be made of manganeſe two parts, and of red-lead and white glaſs, of each one part, twice fuſed.

Glazing, *Fleſh-coloured*, is made of twelve parts of lead-aſhes, and one of white glaſs.

Glazing, *Gold-coloured.* To make gold-coloured glazing, take of litharge three parts; of ſand, or calcined flint, one part: pound, and mix theſe very well together; then run them into a yellow glaſs with a ſtrong fire. Pound this glaſs, and grind it into a ſubtile powder, which moiſten with a well ſaturated ſolution of ſilver; make it into a paſte, which put into a crucible, and cover it with a cover. Give at firſt a gentle degree of fire; then increaſe it, and continue it till you have a glaſs, which will be green. Pound this glaſs again, and grind it to a fine powder; moiſten this powder with ſome beer, ſo that by means of an hair pencil you may apply it upon the veſſels, or any piece of earthen ware. The veſſels that are painted or covered over with this glazing, muſt be firſt well heated, then put under a muffle; and as ſoon as the glaſs runs, you muſt ſmoak them, by holding them over burning vegetables, and take out the veſſels. Mr. Heinſius of Peterſburg, who ſent this receipt to the Royal Society, uſes the words *afflare debes fumum*, which is rendered *ſmoak them*, in the Tranſactions. Phil. Tranſ. N° 465. § 6.

Kunckel gives ſeveral preparations for a gold-coloured yellow glazing. This may be produced by fuſing a mixture of three parts of red-lead, two parts of antimony, and one part of ſaffron of Mars; by again melting the powdered maſs, and repeating the operation four times; or, by fuſing four or five times a compoſition of red-lead and antimony, of each an ounce, and of ſcales of iron half an ounce: or by calcining and fuſing together eight parts of red-lead, ſix parts of flints, one part of yellow ochre, one part of antimony, and one part of white glaſs. A tranſparent gold-coloured glazing may be obtained by twice fuſing red-lead and white-flints, of each twelve parts, and of filings of iron one part.

Glazing, *Green*, may be prepared of eight parts of litharge, or red-lead, eight parts of Venice glaſs, four parts of braſs-duſt, or filings of copper; or, of ten parts of litharge, twelve of flints or pebble, and one of *æs uſtum*, or copper-aſhes.

A fine green glazing may be produced by uſing one part of the Bohemian granate, one part of filings of copper, one part of red-lead, and one part of Venetian glaſs; or by fuſing one part of white glaſs, the ſame quantity of red-lead, and alſo of filings of copper; powdering the maſs, and adding one part of Bohemian granate to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the ſhades and teints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

Glazing, *Iron-coloured*, is prepared of fifteen parts of lead-aſhes, or red-lead, fourteen of white ſand, or flints, and five of calcined copper. This mixture is to be calcined and fuſed.

Glazing, *Liver-coloured*, is prepared of twelve parts of litharge, eight of ſalt, ſix of pebble or flint, and one of mangeneſe.

Glazing, *Purple-brown*, conſiſts of lead-aſhes fifteen parts, clear-ſand, or powdered flints, eighteen parts, mangneſe one part, and white glaſs fifteen meaſures; to which ſome add one meaſure of zaffer.

Glazing, *Red*, is made of antimony three pounds, litharge, or red-lead, three, and ruſt of iron, one; grind them to a fine powder. Or take two pounds of antimony, three of red-lead, and one of calcined ſaffron of Mars, and proceed as before.

Glazing, *Sea green*, is made of five pounds of lead aſhes, one pound of tin-aſhes, three pounds of flint, three quarters of a pound of ſalt, half a pound of tartar, and half a pound of copper duſt.

Glazing, *White.* A fine white glazing for earthen-ware is thus prepared: Take two pounds of lead, and one of tin; calcine them to aſhes: of this take two parts, calcined flint, white ſand, or broken white glaſs, one part, and ſalt one part: mix them well together, and melt them into a cake for uſe. The trouble of calcining the tin and lead may be prevented, by procuring them in a proper ſtate.

The white glazing for common ware is made of forty pounds of clear ſand, ſeventy-five pounds of litharge, or lead-aſhes, twenty-ſix of pot-aſhes, and ten pounds of ſalt: theſe are three times melted into a cake, quenching it each time in clear cold water. Or, it may be made of fifty pounds of clean ſand, ſeventy of lead-aſhes, thirty of wood-aſhes, and twelve of ſalt.

A very fine white glazing may be obtained by calcining two parts of lead, and one part of tin; and taking one part of this maſs, and of flints and common ſalt, of each one part, and fuſing the mixture. See Delf-*ware*.

A white glazing may be prepared by mixing one hundred pounds of maſticot, ſixty-pounds of red-lead, twenty pounds of calcined tin or putty, and ten pounds of common ſalt; and calcining and powdering the mixture ſeveral times.

Glazing, *Yellow*, is prepared of red-lead, three pounds; calcined antimony and tin, of each two pounds: or, according to ſome, of equal quantities of the three ingredients. Theſe muſt be melted into a cake, then ground fine; and this operation repeated ſeveral times: or, it may be made of fifteen parts of lead-ore, three parts of litharge of ſilver, and fifteen parts of ſand.

A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of ſand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fuſing it. Or, take four parts of white glaſs, one part of antimony, three parts of red-lead and one part of iron ſcales, and fuſe the mixture: or, fuſe ſixteen parts of flints, one part of iron-filings, and twenty-four parts of litharge. A light yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glaſs, and two parts of calcined tin. See *Gold-coloured* Glazing.

Glazing, *Citron-yellow*, is made of ſix parts of red-lead, ſeven parts of fine red brick-duſt, and two parts of antimony. This mixture muſt be calcined day and night for the ſpace of four days, in the aſh-hole of a glaſs-houſe furnace, and at laſt urged to fuſion.

Glazing *of Delf-ware.* See Delf-*ware*.

Glazing *of Porcelain.* See Porcelain.

Glazing *of Stone-ware, and Queen's ware.* See Pottery.

Glazing *for Tobacco Pipes.* See Tobacco-pipes.

Glazing, in *Painting*, a term of the art, expreſſive of a peculiar mode or variety in the practice of it. It conſiſts in laying a tranſparent colour, made very thin by a great quantity of oil, or other vehicle, over a ſolid body of opaque colour; and its intent is, to give a greater degree of clearneſs and brilliancy to the colour produced by this proceſs, than can be obtained by mixing together in ſubſtance the two colours thus employed. In this mode their hues are blended, without diſparagement of each other; whereas, in mixing them in the ordinary way, a certain diminution of their brilliancy takes place, produced by the diſſimilar nature of their qualities.

Glazing appears to have been practiſed very early in oil-painting; and probably the uſe of varniſhes over pictures painted with water-colours may have firſt ſhewn its utility. Indeed it could not fail to be the caſe, if the varniſh employed happened to be tinged with any colour; for the luſtre pictures acquired by that circumſtance muſt be ſtrikingly engaging: a harmony and ſweetneſs are thereby gained, which all other means are vainly employed to obtain. It is therefore ſurprizing that all thoſe who practiſed the art of painting after the diſcovery of the uſe of oil, ſhould not have given in to the application of it. Yet it is certain that the Roman ſchool is remarkably deficient in the knowledge of the value of this practice, and moſt frequently neglected to uſe it; owing probably to the employment painting found in freſco. The Venetian and Dutch ſchools, on the other hand, employed it in perfection, and it is in their works that a knowledge of it may beſt be acquired.

The principal difficulty attending the uſe of glazing, is to avoid the too common application of it; as it does not ſuit the repreſentations of all ſubſtances, in its more immediate ſenſe; though one general glaze over a picture, completed in its forms, will at all times benefit the work; if it happens not to be too low, or inſipid, in its tones of colour.

All kinds of gems and poliſhed ſubſtances, ſuch as metals, ſilks, velvets, &c. are imperfectly wrought to effect, when it is not employed; and fleſh, which is in nature compounded of a great variety of colours, is ſeldom quite perfect in its hue, when glazing is not employed to finiſh with. It is a ſpecies of it, produced by the yellow varniſh being but partially removed from old pictures, which gives them their peculiar and brilliant luſtre. It is quite impoſſible to make any effect exactly like it with freſh colours, unleſs ſome artifice be uſed to forerun the effects of time; ſuch as rubbing in dirt, and then partially removing it, &c. tricks which picture dealers are perfectly converſant with; and by which many an ingenious copy is paſſed off upon the unlearned amateur, to the enrichment of the dealer, and the future annoyance of the buyer, when time and improved information let him into the ſecret.

Glazing is the moſt valuable part of the practice of painting, when judiciouſly employed; as it produces clear broken tones of colour, which leave no remembrance of the paliette, but deceive the eye by the variety of hues, and dazzling effect of light, produced by one colour ſhining through another in different degrees of illumination; much more like the effects of natural objects, than the uſe of opaque colours can poſſibly produce. But then great dexterity and judgment are required to uſe it properly in ſo general a manner. A well-informed and ſcientific artiſt knows the tone which one colour glazed over another will produce; and without that knowledge, a dirty dulneſs may be the effect, inſtead of the clearneſs required: and if not ſucceſsful, it is always injurious; there is no medium in the application of it. If the under colour is not improved, it is ſure to be deteriorated; and it will require repainting, to reſtore its original freſhneſs. So that when a painter has prepared a work for glazing, (which ſhould always be done with great clearneſs and preciſion,) the moſt extreme caution is requiſite in adapting the tone of the glaze which he propoſes to uſe to the general hue of the picture before he applies it. It is not poſſible to give rules more explicit on this matter; the indefinite ſubdiviſions of hues which all colours are capable of, muſt for ever leave to the feeling and judgment of the artiſt their peculiar application. It is hardly neceſſary to ſtate that a glaze of red, over blue, will produce purple; of blue, over yellow, green; and of red, over yellow, orange; but it may aid the ſtudent in his practice, if he conſiders, that all the varieties of tone the original colours are capable of, will, when equally employed, produce a correſponding compound; and, of courſe, if his picture be of too red a hue, though of a light tone, a correſponding one of blue, or of yellow, will change it to the one he may require; and if he uſe the blue and yellow together as a green, it will produce a negative colour; totally deſtroying the red: but the varieties are too complicated and numerous to follow.

Glazing *of Cloth*. The proceſs of glazing is uſed for all the ſtout fabrics of cotton goods, and ſometimes for thoſe of linen. It is a part of the general proceſſes of finiſhing goods for the market, and which is carried on by thoſe who are generally called cloth-lappers, or calendermen. The glazing is done by putting on the cloth a ſmall quantity of white wax, ſuch as that uſed in the manufacture of wax candles, and the gloſs is afterwards effected by the friction of any ſmooth body on the ſurface of the cloth. By the ordinary proceſs the apparatus is very ſimple, conſiſting merely of a ſmooth table, a little inclined towards the operator, like a common writing deſk, upon which the cloth to be glazed is ſpread ſmoothly, and drawn over, as occaſion requires, from one end of the piece to the other. Above this is a lever, ſuſpended from any convenient fixture to the roof, the lower end hanging in contact with the cloth, and by moving this backward and forward, the neceſſary friction is produced. The end of the lever next to, and in contact with the cloth, is faced with a ſmooth piece of flint or pebble, finely poliſhed, and of a cylindrical form, the under ſurface of which is in contact with the cloth. This lever being drawn backward and forward by the operator's hands, the whole cloth is poliſhed or glazed in ſucceſſion, the joint at the top of the lever being fitted into a horizontal ſlider, which allows the poliſher or flint to be moved from one ſide of the cloth to the other. In this way of glazing, the whole is performed by the power of a man's arms and hands; and, from the poſition of his body being conſtantly inclined over the table, is found to be a very laborious and fatiguing operation. The great number of people neceſſarily employed by this operation, and the difficulty of getting large quantities of goods rapidly glazed to anſwer the demands of hurried ſhipments for exportation, ſuggeſted lately the idea of a more ſpeedy and efficacious manner of performing the operation of glazing by an improvement and alteration in the conſtruction of the common five-bowl calender. This improvement was planned and executed at the extenſive works of the late Mr. John Miller of Glaſgow, who furniſhed the inventor with the means of carrying his plan into effect, and upon a proof of its efficacy on trial, his majeſty's royal letters patent for its excluſive uſe to the inventor or his aſſignees within Scotland were obtained in the uſual form. Two or three machines were then conſtructed for his own works, to which, as far as we know, they are ſtill confined; and theſe machines have given the moſt univerſal ſatisfaction to all who have had their goods glazed by them, while at the ſame time an immenſe reduction of labour has been effected by their uſe.

The patent glazing machine, like the common calender, conſiſts of five bowls, or cylinders, four of which are of caſt iron, ſmoothly turned, and finely poliſhed on the ſurface, and the large or intermediate cylinder is generally of paſteboard on an iron axis. In the common operation of ſmoothing by means of the calender, the velocity of the cylinders revolving upon their own *axes*, is in the ratio of their reſpective diameters, ſo that an equal quantity of ſuperficies is conſtantly expoſed of each. In the glazing-calender, or machine, it is only neceſſary that the motions of one of the cylinders ſhould be ſo much accelerated as to produce the friction neceſſary to effect the glazing by rubbing againſt the other cylinders with which it is in contact, ſo as not to be liable to tear or otherways injure the fabric. This motion is produced by means of wheels placed in the following manner: On the axis of the main cylinder A, is a caſt iron wheel of any convenient diameter and number of teeth. This wheel works into the ſtud-wheel B, the number of whoſe teeth is not material to the ſpeed, and whoſe diameter may be regulated ſo as to pitch well into the remaining wheels. The wheel is placed to revolve looſely on an iron ſtud, ſcrewed into the frame-work of the machine. The ſtud-wheel B gives motion to the ſecond ſtud-wheel C, and it continues the motion to the wheel D, which is faſtened on the axis of the firſt iron cylinder. The upper cylinder works merely by friction, as in a common calender, and when the intermediate ſtud-wheel B is removed by being taken off the ſtud, the whole cylinders will revolve exactly as in the common machines, without producing any glazing effect. The ſimplicity of this machine, the regularity of the gloſs which it gives, and the immenſe ſaving of labour, are powerful recommendations in its favour. The great quantity alſo which may be effected by it in a very limited time, renders it peculiarly adapted to meet the occaſional exigencies of the exporter; and the additional advantage of its facility of adaptation to the purpoſes of the common calender, when glazing is not required, adds to its value and utility. Upon preſſing occaſions, one of theſe engines, by being conſtantly employed night and day, will glaze from 600 to 800 pieces of cloth, of 28 yards each, weekly.

Thoſe employed in the late Mr. Miller's works are driven by means of a ſteam engine, by which alſo various other kinds of machinery, adapted to the various operations of the buſineſs, are ſet in motion Should any machinery of this deſcription be conſtructed in works where there may be a general neceſſity of keeping them conſtantly employed for the purpoſe of glazing, it will be very neceſſary that care ſhould be taken that the moving power, whether water, ſteam, or horſes, ſhould be ample; as it muſt be evident, even to thoſe who are not practically converſant with the calculation of power and reſiſtance, that this calender, when employed to glaze, muſt require conſiderably greater force to keep it in motion, than when the cylinders revolve in the ratios of their diameters, for the mere purpoſe of common calendering or ſmoothing.

We are not in poſſeſſion of ſufficient *data* to enable us to aſcertain, with any tolerable preciſion, the quantum of reſiſtance added by the friction; nor are we aware that any accurate experiments have been made for that purpoſe: but it is evident that it muſt be very great in all caſes. It is reaſonable alſo to infer, that it may be conſiderably increaſed or diminiſhed by the texture or fabric of the ſtuff upon which the glazing operation is performed. Hence, if theſe machines be employed conſtantly in large works, and ſet in motion by the ſame power, which alſo drives machinery adapted to other purpoſes, care muſt be taken that the power be ſufficient to effect all the various purpoſes to which it is applied. And ſhould this be attempted, under the impreſſion that the glazing might be performed by the ſame power as common calendering, a deficiency would be found, which muſt render it neceſſary to diſengage part of the machinery, in order to give ſufficient momentum to the reſt. This is, perhaps, one of the moſt common, and at the ſame time, moſt ruinous errors into which the projectors of large works, who are not mechanics, are apt to fall. In the firſt inſtance, deſirous that a large eſtabliſhment ſhould be ſet to work at the leaſt poſſible expence, they too frequently calculate too barely, and are then obliged either to abandon their whole ſcheme at a great loſs, to work it under ſerious and ruinous inconveniences, or to repair, at a triple expence, what they have left deficient at firſt.

GLAZOV, in *Geography*, a town of Ruſſia, in the government of Viatka, on the Tchevtza; 56 miles E.S.E. of Viatka. N. lat. 58° 5'. E. long. 51°.

GLEAD, or GLADE, in *Ornithology*, a name uſed in the northern parts of the kingdom for the *milvus*, or *kite*. See FALCO *Milvus*.

GLEAM is popularly uſed for a ray or beam of light. Among falconers, a hawk is ſaid to gleam, when ſhe caſts or throws up filth from the gorge.

GLEAN, in *Geography*, a river of England, which riſes about four or five miles N. of Stamford in Lincolnſhire, and runs into the eſtuary called the Waſh, five miles N.E. of Spalding.

GLEANING, the act of gathering or picking up the ears of corn left behind, after the field has been reaped, and the crop carried home.

By the cuſtoms of ſome countries, particularly thoſe of Melun and Eſtampes, all farmers and others are forbidden, either by themſelves or ſervants, to put any cattle into the fields, or prevent the gleaning in any manner whatever, for the ſpace of twenty-four hours after the carrying off the corn; on penalty of confiſcation, &c. It hath been ſaid, that by the common law and cuſtom of England the poor are allowed to enter and glean upon another's ground after the harveſt, without being guilty of treſpaſs. Gilb. Jo. 253. Trials *per pais*, ch. 15. 438. This humane proviſion ſeems to be borrowed from the Moſaic law. Levit. xix. 9. xxiii. 22. Deut. xxiv. 19, &c.

Gleaning is a practice that is little heard of in the more northern parts of the kingdom, but which prevails greatly in ſome of the ſouthern diſtricts. The cuſtom is of great antiquity; and whether or not the poor have any legal right, in this country, to glean, except by the expreſs permiſſion of the farmer, it has however been ſo long ſanctioned by its continuance, that it is but rarely interrupted or put a ſtop to by him.

In ſome places where it is carried on to exceſs, it would ſeem neceſſary for the farmers to make regulations in reſpect to it, that ſhould not be broken through on any account whatever. If this be not the caſe, the abuſe is frequently ſo great that they are much injured by it, "as the poor glean among the ſheaves, and too often from them," as is notorious to thoſe who have attended to the practice. It has been therefore ſuggeſted to make it a rule not to ſuffer a gleaner to enter a wheat field until it is wholly cleared of the crop, which would, no doubt, prove a very beneficial regulation. It does not, however, upon the whole, appear that much benefit is derived to the poor from the cuſtom, while it evidently leads to idleneſs, immorality, pilfering, and a looſeneſs of diſpoſition.

GLEBA ALANA, a name by which ſome call the yellowiſh white tripoli.

GLEBÆ, *Addicti*. In the civil law, ſlaves were ſaid to be annexed to the glebe; *i. e.* they went with it, were ſold with it, &c.

The right of patronage ſhould be annexed to a glebe.

GLEBE, Gleba, in *Natural Hiſtory*, *Chemiſtry*, &c. a clod, or piece of ſtone or earth, frequently containing ſome metal, or mineral.

The glebes are carried to the forges to be waſhed, purified, and melted, &c.

Glebe, or *Glebe-land*, is properly uſed for church-land ; "Dos vel terra ad eccleſiam pertinens."

Glebe-land is moſt commonly uſed for land belonging to a pariſh-church, beſide the tithes.

Thus, Lindwood: "Glebe eſt terra in qua conſiſtit dos eccleſiæ ; generaliter tamen ſumitur pro ſolo, vel pro terra culta." Though in the moſt general, and extenſive uſe of the word, glebe is applicable to any land or ground belonging to any benefice, fee, manor, inheritance, or the like.

If any parſon, vicar, &c. hath cauſed any of his glebe lands to be manured and ſowed at his own coſts, with any corn or grain, the incumbents may deviſe all the profits and corn growing upon the ſaid glebe by will. (Stat. 28 H. 8. cap. 11.) And if a parſon ſows his glebe and dies, the executors ſhall have the corn ſowed by the teſtator. But if a glebe be in the hands of a tenant, and the parſon dies after ſeverance of the corn, and before his rent due ; it is ſaid, neither the parſon's executors nor his ſucceſſor can claim the rent, but the tenant may retain it and alſo the crop, unleſs there be a ſpecial covenant for the payment to the parſon's executors proportionably, &c. Wood's Inſt. 163.

GLEBEC, in *Geography*, a town of America, in the ſtate of Virginia ; 10 miles S.E. of Tappahanoc.

GLEBOUS, in *Rural Economy*, a term ſometimes provincially ſignifying the turf or graſſy ſurface.

GLEBOW, in *Geography*, a town of the duchy of Courland ; 18 miles S. of Mittaw.

GLECHOMA, in *Botany*, is derived from Γληχων of Dioſcorides, though the latter is uſually taken for *Pulegium*, or Penny-royal.—Linn. Gen. 291. Schreb. 388. Willd. Sp. Pl. v. 3. 85. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 625. Juſſ. 113.—Claſs and order, *Didynamia Gymnoſpermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, tubular, cylindrical, ſtriated, very ſmall, permanent ; its mouth having five ſharp unequal teeth. *Cor.* of one petal, ringent ; tube ſlender, compreſſed ; upper lip erect, obtuſe, lower lip ſpreading, larger than the upper one, obtuſe, three-cleft, its middle lobe larger, emarginate. *Stam.* Filaments four, under the upper lip, two of which are ſhorter ; each pair of anthers forming themſelves into a croſs. *Piſt.* Germen four-cleft ; ſtyle thread-ſhaped, bending under the upper lip ; ſtigma cloven, acute. *Peric.* none ; the calyx nouriſhing four, ovate *ſeeds* in its boſom.

Eſſ. Ch. Calyx five-cleft. Each pair of anthers converging in form of a croſs.

1. G. *hederacea*. Ground-ivy. Linn. Sp. Pl. 807. Engl. Bot. t. 853.—"Leaves kidney-ſhaped, crenate."—Found in woods and hedges, flowering in April and May. *Root* perennial, and creeping. *Leaves* on foot-ſtalks, dotted beneath with glandular points. *Flowers* axillary, about three to each leaf, prettily ſpeckled with white and blue. *Calyx* ſtriated. *Anthers* white. Ground-ivy has been ſo long and ſo generally known, that it has obtained various appellations, ſuch as Ale-hoof, Gill, Robin-run-in-the-hedge, Cat's-foot, &c. Before the introduction of Hops its leaves ſeem to have been uſed for flavouring and clarifying ale. Gerarde has enumerated a long train of "Vertues" ſuppoſed to be poſſeſſed by this plant ; and when infuſed into tea or honey, it is ſtill a favourite medicine with the common people for coughs. Many animals eat it, though it is ſaid to injure horſes if taken too copiouſly. The ſpecific character is now ſuperfluous, as two ſpecies enumerated in the firſt edition of the *Species Plantarum* are now referred to other *genera*.

Glechoma *Hederacea*, *ground-ivy* or *gill*, in the *Materia Medica*, is a well known plant, growing commonly under hedges and flowering in April. Ground-ivy has a peculiar ſtrong ſmell ; the leaves, according to Dr. Withering, being beſet underneath with hollow dots, in which are glands ſecreting an eſſential oil, and above with little eminences, which do not ſecrete any odoriferous oil ; for this ſurface, when rubbed, yields no peculiar ſcent, whereas the under ſurface affords a pleaſant reviving ſcent. The taſte is bitteriſh, and ſomewhat aromatic. This plant was formerly ſuppoſed to poſſeſs great medicinal powers, not diſcovered by later experience ; accordingly it is omitted in the materia medica by the London college. Its qualities have been deſcribed by different authors, as pectoral, detergent, aperient, diuretic, vulnerary, corroborant, errhine, &c. and it has been recommended for the cure of thoſe diſeaſes to which theſe powers ſeem to be moſt adapted, but chiefly in pulmonary and nephritic complaints. In obſtinate coughs it is a favourite remedy with the poor, who, probably deriving benefit from it, perſiſt in its uſe. Ray, Mead, and ſome others, ſpeak of its being uſefully joined with fermenting ale ; but Dr. Cullen obſerves, "it appears to me frivolous. In ſhort, in many caſes where I have ſeen it employed, I have had no evidence either of its diuretic or of its pectoral effects. In common with many others of the verticillatæ, it may be employed as an errhine, and in that way cure a head-ache, but no otherways by any ſpecific quality." It is uſually taken in the way of infuſion, or decoction, as tea. Woodville Med. Bot.

GLECHONITES, a name given by the ancient *Phyſicians*, to a ſort of wine impregnated with penny-royal, much recommended in all obſtructions. It takes its name from *glechon*, the Greek name of *penny-royal*, or *pulegium*.

GLEDITSIA, in *Botany*, named by Clayton, and adopted by Linnæus, in honour of Dr. John Gottlieb Gleditſch, profeſſor of medicine and botany at Berlin, an advocate of Linnæus againſt Sigeſbeck, and author of a *Syſtema Plantarum*, founded on the inſertion of the ſtamens, as well as of an arrangement of *Fungi*, and various other botanical treatiſes in Latin and German. He died in 1786, aged 72. Linn. Gen. 549. Schreb. 735. Ait. Hort. Kew. v. 3. 444. Mart. Mill. Dict. v. 2. Juſſ. 346. Lamarck Illuſtr. t. 857. Gærtn. t. 146. Claſs and order, *Polygamia Diœcia*; or rather *Diœcia Hexandria*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of three ſmall, ſpreading, acute leaves. *Cor.* Petals three, roundiſh, ſeſſile, ſpreading, reſembling the calyx-leaves. Nectary turbinate, united by its border to the other parts of fructification. *Stam.* Filaments ſix, thread-ſhaped, longer than the corolla; anthers oblong, compreſſed, two-lobed, incumbent.

Female, on a ſeparate plant, *Cal.* Perianth like the male, but of five leaves. *Cor.* Petals five, long, acute, rather ſpreading. Nectaries two, ſhort, like abortive filaments. *Piſt.* Germen ſuperior, broad, compreſſed, longer than the corolla; ſtyle ſhort, reflexed; ſtigma thick, the length of the ſtyle, to which it is longitudinally affixed, downy in the upper part. *Peric.* Legume very large, broad, compreſſed quite flat, divided by numerous tranſverſe partitions, and filled with pulp. *Seeds* ſolitary, roundiſh, hard, and poliſhed.

At the ſummit, generally, of the male ſpike is an united flower, with four calyx-leaves and as many petals, with a nectary and ſtamens like the male, but with a piſtil, producing perfect fruit, as in the female. Hence Linnæus referred this genus to his claſs *Polygamia*, but if it remains there it muſt rather be on account of the difference of ſtructure in its male and female flowers, than for their ſlight ſexual anomalies. Even for this difference of ſtructure we ſhould rather place it in *Diœcia*. See Sm. Introd. to Botany, 470, 485.

Obſ. This genus has conſiderable affinity with *Ceratonia*, eſpecially in the fruit. We cannot apply the term *amentum* to its infloreſcence, which is a ſpike.

Eſſ. Ch. Male, Calyx of three leaves. Petals three. Nectary turbinate. Stamens ſix.

Female, Calyx of five leaves. Petals five. Nectaries two. Piſtil one. Legume.

Some flowers united, four-cleft.

The ſpecies of *Gleditſia* are as yet a maſs of confuſion. *G. triacanthos*, Linn. Sp. Pl. 1509, the original one, a native of North America, was cultivated by biſhop Compton in 1700, and is a tall handſome tree, which bears our climate well, except being ſometimes broken, like *Robinia Pſeudo-acacia*, by ſtrong winds. It is remarkable for its large trifid or compound ſpines, which grow on the trunk to the length of ſix or eight inches, from a very ſlender baſe. The leaves are deciduous, bipinnate, large, conſiſting of innumerable elliptical, ſlightly toothed, nearly ſmooth leaflets, half an inch or near an inch long. Flowers greeniſh, in axillary ſpikes. Some leaves appear to be ſimply pinnate, but we know not whether this is a ſpecific difference or not.

A very diſtinct ſpecies is cultivated with us by the name of *G. chinenſis*, which Linnæus alſo had at Upſal, but he does not ſeem to have deſcribed it The ſpines are compound. Leaves ſimply and abruptly pinnate, of ſeven or eight pair of thin, ſquariſh, unequal-ſided, crenate leaflets, gradually larger upwards, the terminal pair being ſometimes twice the dimenſions of the next.

In Sion gardens, belonging to the duke of Northumberland, is a tree of another ſpecies, of which we find no mention. Its leaves are ſimply pinnate like the laſt, and the leaflets alſo gradually larger upwards, but they are coriaceous, elliptical, their ſides very ſeldom unequal. The calyx-leaves and petals are narrower, ſhorter, and blunter than in *G. triacanthos*. Of its ſpines we have no account, but the leaves and flowers were communicated to us by Mr. Hoy, in Auguſt 1796, as a *Gleditſia* not in the *Hortus Kewenſis*, where, indeed, all that are known are made varieties of the *triacanthos*. From the new edition of this valuable work perhaps more information may be expected.

G. inermis, firſt mentioned by Linnæus in the ſecond edition of Sp. Pl. 1509, ſeems to have been adopted without a ſpecimen, from Plukenet's t. 123. f. 3, to which is added Miller's t. 5, which laſt repreſents a *Mimoſa*, nor does any ſubſequent writer appear to know any thing of this ſpecies.

It would be a tedious and unprofitable taſk to attempt a determination of the ſynonyms of this genus, even if the ſpecies were defined. The latter is a deſirable object, and worthy the attention of thoſe who have perpetual acceſs to the old botanic gardens about London, and can obſerve theſe trees at different periods of growth. It is neceſſary to determine whether the ſimply or doubly pinnated leaves mark a ſpecific diſtinction; whether the ſpines vary according to the age of the tree; and whether the legume is, in any ſpecies, conſtantly ſingle-ſeeded, or merely from accidental abortion. Travellers in America can ſcarcely be expected to throw any light on ſuch botanical queſtions as theſe, though a careful obſerver, reſident there, might render highly important ſervices to botany, and to the moſt uſeful arts of life, by determining firſt the ſpecific differences, and then the economical qualities, of all the American trees, among which the *Gleditſiæ* claim a diſtinguiſhed place. The labours of a Lambert among the Pines, and a Michaux among the Oaks, are models for future enquirers.

GLEDITSIA, in *Gardening*, comprehends a plant of the deciduous tree or ſhrub kind; of which the ſpecies uſually cultivated is the three-thorned acacia (G. triacanthos), which ſeldom riſes higher than a ſhrub in this country.

There are ſeveral varieties with different numbers of ſpines, and with ſtronger and weaker ſpines.

Method of Culture.—Theſe trees are capable of being increaſed by ſowing the ſeeds, which are obtained freſh from America, in a bed of light earth, in the early ſpring ſeaſon, watering them occaſionally when the ſeaſon is dry. It is, however, a much more expeditious practice to ſow them in pots, and plunge them in a moderate hot-bed. The plants ſhould be kept clean during the firſt ſummer after they appear, and in the ſucceeding winter be well protected from ſevere froſts, eſpecially ſuch as are in pots.

The young plants may, moſt of them, in the following ſpring, be removed and ſet out into nurſery rows, at a foot or eighteen inches diſtant from each other, and eight or ten inches in the rows. Such ſmall plants as remain, may be put out in the ſame manner in the next autumn or ſpring.

The plants ſhould continue in this ſituation till they have had two or three years growth, after which they may be tranſplanted into the ſituations in which they are to remain any time towards the latter part of the ſpring ſeaſon.

Theſe plants are found to ſucceed beſt in ſituations where the ſoils are of the more light deep kinds, and rather ſheltered from the inclemency of the atmoſphere.

They are all very ornamental trees, and well adapted to large ſhrubberies, plantations, and pleaſure grounds. When planted alone, on lawns, and large open ſpaces that are kept in ſhort graſs, they produce a fine appearance. They have, however, the diſadvantage of putting forth their leaves at rather a late period.

GLEE, a muſical term derived by Skinner, Junius, Johnſon, and all the etymologiſts, from ȝlıȝȝe, Saxon, *joy*, *mirth*, *ſport*.

> His merry men commaunded he
> To maken him both game and glee.
>
> Chaucer, Rim. S^{r}. Tap. v. 126.

The term, we believe, is not to be found in muſic-books, or muſical writers, before the middle of the 17th century. The firſt time it appears in the title of a collection of canons, rounds, and catches, is in a publication by John Playford, 1667, under the title of "Dialogues, Glees, Ayres, and Ballads, of two, three, and four Voyces."

A glee in muſic implies nothing more in its original ſenſe, in our printed muſic-books, than "a ſong of three or more parts, upon a gay or merry ſubject, in which all the voices begin and end together, ſinging the ſame words." When ſubjects of fugue or imitation occur, and the compoſition is more artificial than ſimple counterpoint, it leſs reſembles a glee than a madrigal, which it might, with more propriety, be called, if the words are ſerious: for a ſerious glee ſeems a ſoleciſm, and a direct contradiction in terms. The word glee, in Saxon, German, and Engliſh dictionaries, ancient and modern, implying *mirth*, *merriment*, and in Chaucer and other old authors, *muſic* itſelf.

GLEET, in *Surgery*, commonly ſignifies the continuation of a thin diſcharge from the urethra, after the inflammatory ſymptoms of a clap have for ſome time ceaſed. However, the running which takes place from the urethra, in caſes of ſtrictures, diſeaſed proſtate gland, &c. is alſo frequently called a gleet. A mere gleet, unattended with any other diſeaſe of the parts, is not accompanied with the remarkable pain and ſcalding ſenſation in making water, which are produced by gonorrhœa. The latter affection may be conſidered as *acute*, while the gleet is quite of a *chronic* nature. It was one of the opinions of Mr. Hunter, that a gleet differed from a gonorrhœa, likewiſe, in not being infectious. It is well known that it was one of the doctrines of this eminent ſurgeon, that the poiſon of gonorrhœa, and that which is productive of lues venerea, are of the ſame quality, and that the different effects are owing to the different ſtructure of the parts concerned in the two diſeaſes. We need not here enter into an inveſtigation of this part of the ſubject. All that we wiſh to obſerve is, that if Mr. Hunter means, when he ſtates, that a gleet differs from a gonorrhœa in not being *infectious*, that a gleet is *not capable of communicating the venereal diſeaſe*, no one can queſtion the accuracy of the obſervation. But, on the contrary, if the aſſertion implies that the matter of a gleet, when applied to the pudenda muliebria, will not bring on a pain in making water, a diſcharge, &c. then we diſſent from the opinion altogether. We have known an inſtance, in which a gentleman, who had had a gleet upon him for upwards of a year, and who, on the preſumption that it was not infectious, ventured to have connection with a young woman, of whoſe continency, with regard to other men, we ourſelves entertain no doubt. However, there may be gleets of various kinds, and ſome of them may be infectious, and others not ſo. When, after a gonorrhœa, a thin diſcharge continues, for a long while, to take place from the urethra, the complaint may depend upon a weakneſs of the veſſels, or, as Mr. Hunter expreſſes it, upon a habit of action, which the parts have contracted. When a gleet ariſes from a ſtricture in the paſſage, or from a diſeaſe of the proſtate gland, the cauſe muſt be referred to irritation, and the cure depends on the removal of the original complaint.

Gleets, which are the conſequence of gonorrhœa, are often exceedingly difficult of cure, and what is very curious, it frequently happens, that, after they have reſiſted every ſort of remedy, and after the patient has long given up the uſe of medicines and injections, a ſudden cure ſpontaneouſly occurs. Many gleets undergo a temporary ſtoppage under particular modes of treatment; but, as ſoon as this is remitted, regularly return again. A vaſt number of gleets depend upon the preſence of a ſtricture in the urethra, and of courſe are not curable by injections. We have often thought that in all caſes of gleets, it ſhould be the invariable cuſtom of the ſurgeon to introduce a bougie, for the purpoſe of aſcertaining whether there is any obſtruction in the paſſage; for, when the diſcharge depends on a ſtricture, the patient might make uſe of balſams, turpentines, and bougies, for years, and yet receive no benefit whatever. At all events, whenever a gleet reſiſts ordinary means, the ſtate of the urethra and of the proſtate gland ought to be examined. See Prostate Gland, *Diſeaſe of*; and Stricture.

Mr. Hunter was of opinion, that the ſpontaneous diſappearance of a gleet, after a long reſiſtance to every ſort of medicine and application, very frequently depended upon accidental changes in the patient's conſtitution. It was another ſentiment of this celebrated ſurgeon, that ſome gleets were connected with ſcrofula. This idea is founded on the circumſtance, that more gleets may be cured by ſea bathing, than any other kind of bathing. It is alſo ſupported by the fact, of ſea water being ſometimes an effectual means of cure, when employed as an injection.

We have always found fault with this plan of judging of the nature of diſeaſes. If a diſorder yields to mercury, practitioners are apt to decide immediately, that the complaint is venereal. If a malady, like a gleet, gives way to ſea bathing, which benefits ſcrofulous complaints, ſuch ſurgeons, as reaſon on Mr. Hunter's principles, will immediately ſet down the caſe as ſcrofulous. It is never remembered in this calculation, that mercury cures many diſeaſes beſides the venereal; and ſo does ſea bathing many complaints beſides thoſe which are of a ſcrofulous nature.

Gleets have alſo been repreſented as always connected with a relaxed conſtitution, though we think we have ſeen the complaint in ſubjects, who were ſtrong, robuſt, and young, with every appearance of general health, and whoſe ſtate ſeemed to us a ſtriking contradiction to the foregoing obſervation.

Gleets, as we have before ſtated, are often exceedingly difficult of removal. Sometimes, indeed, they may be got rid of with tolerable eaſe; but in other inſtances, they completely fruſtrate the art of ſurgery, and the patient, tired of the inefficacy of different remedies, relinquiſhes the trial of all. In ſlight caſes, and occaſionally in inveterate ones, a cure may be effected by exhibiting internally the balſam of copaiva, the oleum terebinthinæ, or the tincture of lyttæ (cantharides). It is well worthy of notice, that when a cure can be accompliſhed by theſe means, benefit is ſoon derived from their employment. For this reaſon, when they neither diminiſh, nor remove the gleet in the courſe of five or ſix days, Mr. Hunter made it a rule never to continue their uſe any longer, but have recourſe at once to other methods. We have already remarked the great tendency of many gleets to return, after being for a time ſtopped by different modes of treatment. Hence practitioners ſhould never diſcontinue the ſucceſsful plan immediately the diſcharge ceaſes, but perſiſt in its adoption for ten days or a fortnight, after all the ſymptoms have entirely gone off.

In relaxed habits, gleets are very likely to be cured by the cold bath, ſea bathing, bark and ſteel medicines. Cold bathing indeed often ſucceeds in every kind of conſtitution, when other methods are of no avail. We have known ſtrong young men labouring under gleets, who could not get rid of them in any way in London; but who got well almoſt immediately on going to the ſea ſide, and bathing there. There can be no doubt alſo, that ſome beneficial revolution in the ſyſtem, ariſing from the change of air, might have a conſiderable ſhare in the cure. We lately had under our care a gentleman with a gleet, which had laſted nine months, but diſappeared all at once on the patient going for a ſhort time to a part of the country which was not near the ſea.

There are two principal kinds of injections in uſe for the cure of gleets, *viz.* aſtringent and irritating ones.

The aſtringent ones are, for the moſt part, ſuch as the decoction of bark, and ſolutions of zincum vitriolatum, alum, or acetite of lead. An injection of proper ſtrength, containing cuprum vitriolatum, bolus gallicus, and camphor, is alſo an exceedingly eligible one.

The beſt irritating injection which we know of, is that made by diſſolving two grains of the hydrargyrus muriatus in eight ounces of diſtilled water.

Bougies may alſo be conſidered as acting on the urethra as irritating applications, and hence they are occaſionally recommended to be worn for the cure of gleets. In general, common bougies are employed; but ſometimes others, medicated with camphor or turpentine, are uſed.

In irritable conſtitutions, the latter kind of injection and the bougies may excite a good deal of irritation, pain, ſtranſgury, &c. ſo that ſome circumſpection is neceſſary in the employment of ſuch means. We may ſtate, indeed, that no endeavour ſhould ever be made to cure a gleet, by exciting irritation in the urethra with ſtimulating injections, or bougies, before milder means have failed. We have found a weak injection of the hydrargyrus muriatus more frequently ſucceſsful than any other. One grain to ſix ounces of water is quite ſtrong enough to begin with, and the ſtrength may be gradually augmented, in proportion as the urethra appears capable of bearing it. The practitioner muſt not leave off the injection as ſoon as the diſcharge ceaſes; for if he does ſo, the gleet will generally recur. The plan ſhould ſtill be followed up for about a fortnight.

When gleets are to be cured by bougies, it is neceſſary to wear theſe inſtruments about a month or ſix weeks before any dependence can be put in the permanence of the cure.

Neither the ſurgeon nor the patient ſhould be deterred from perſiſting in the trial of irritating injections or bougies, by the circumſtance of their appearing to increaſe the diſcharge at firſt. This they always do.

Mr. Hunter thought that moderation and regularity in diet were conducive to the cure of gleets. So is a quiet kind of life in the generality of caſes, but there are inſtances in which gleets ſeem to be benefited and cured by rough exerciſe on horſeback.

A return or an increaſe of a gleet is very apt to be the conſequence of intercourſe with women, and the patient often thinks that he has received a freſh infection. Mr. Hunter thought that the caſe might be diſcriminated by the ſhort time which intervenes between the connection and the re-appearance of the diſcharge. Gleets are often ſo exceedingly obſtinate, that the ſurgeon cannot be informed of too many modes and principles of cure. On this account we deem it right to mention that gleets ſeem to be curable on the principle of counter-irritation. Hunter has ſeen a gleet ſtop on the breaking out of two chancres on the glans penis, and the diſcharge has been known to ſtop as ſoon as a bliſter was applied to the under part of the penis.

Gleets have likewiſe been cured by electricity.

Women are liable to gleets, and the diſeaſe being ſituated in leſs irritable parts, whatever injections are uſed, may be made ſtronger than for male patients.

It is almoſt unneceſſary to remark, that balſams and turpentines, internally given, can have no ſpecific effect on the parts affected in women, as they have on the urethra in men. Hence it would be abſurd to preſcribe ſuch medicines for female patients.

GLEIBERG, or GLITZBERG, in *Geography*, a town of Germany, in the principality of Naſſau Weilburg; eight miles N.E. of Wetzlar.

GLEICHAN, a county of Germany, in the principality of Gotha, divided between the princes of Gotha, Hohenloe, Hatzfield, and Schwartzburg, ſituated on the banks of the Ohr, between Erfurt and Gotha.

GLEICHEN, FREDERIC VON, in *Biography*, was born in the year 1714. He was intended and educated for the profeſſion of arms, and ſpent the early part of his life as an officer in the ſervice of Bayreuth, and was diſtinguiſhed by his attention to military diſcipline. He roſe to the rank of lieutenant-colonel, and obtained the favour of the margrave. His honours did not ſit eaſy upon him, he ſighed for retirement, and in 1756 his wiſhes were accompliſhed; he obtained a diſmiſſion from the ſervice with a handſome penſion, to which was afterwards added the rank of privy counſellor. He now had leiſure to diſtinguiſh himſelf as a philoſopher, a naturaliſt, and a writer. His attention was accidentally excited to microſcopical obſervations, and not ſatisfied with the inſtruments already in exiſtence he conſtructed an univerſal microſcope, with which he combined the ſolar microſcope. His principal obſervations relate to ſeminal animalcula, and infuſion animals: he would ſit day after day at his glaſs, and was always diſpleaſed if he experienced any interruption while engaged in his favourite purſuit. By daily practice he had acquired uncommon acuteneſs of ſight, which was of the greateſt advantage to him in his reſearches. Though he had an ardent attachment to ſcience for the love of it, yet he deviſed various economical plans, from which he expected to derive great emolument, but they were the ſchemes of a theoriſt, and did not prove of real advantage either to himſelf or the world. He died in June 1783, leaving behind him numerous works in natural hiſtory, as "Obſervations on the Parts of Fructification in Plants when in bloom, and on the Inſects found in them:" "Hiſtory of the Common Houſe Fly:" "Treatiſe on ſeminal Animalcula and infuſion Animals:" "Eſſay towards the Hiſtory of the Tree-louſe of the Elm:" this inſect, the aphis ulmi campeſtris, coſt our author the labour of eight years; it is the cauſe of the bladders on the leaves of the elm-tree during the ſpring. Gen. Biog.

GLEICHENBERG, in *Geography*, a town of the duchy of Stiria; 10 miles N. of Racklſburg.

GLEICHENBERGAN, or GLEICHEM BERG, a town of Germany, in the county of Henneberg; four miles E. of Romhild.

GLEICHENIA, in *Botany*, named by the writer of this article in honour of Philip Frederick, Baron von Gleichen, author of a ſplendid microſcopical work on the ſtructure and phyſiology of the parts of fructification in ſeveral plants, publiſhed at Nuremberg, in folio, with coloured plates, in 1764. As the ſeeds of ferns were among the ſubjects to which Baron Gleichen paid great attention, a genus belonging to this curious tribe was judged peculiarly proper to commemorate him. Smith in Mem. de l'Acad. de Turin, v. 5. 419. t. 9. f. 10. Tracts, 258. t. 1. f. 10. Swartz. Fil. 165. Brown. Prod. v. 1. 160. (Mertenſia; Willden. in Act. Holm. ann. 1804. 165. t. 4, 5. Swartz. Fil. 163.)—Claſs and order, *Cryptogamia Filices*: ſect. *Annulatæ*. Nat. Ord. *Filices dorſiferæ*.

Eſſ. Ch. Capſules in a ſimple, concentric, orbicular ſeries; each ſeries conſtituting a round ſeparate dot, on the back of the leaf. Cover none.

This genus was firſt founded on the *Onoclea polypodioides* of Linnæus, an elegant and ſingular fern, native of the Cape of Good Hope. In this the capſules are uſually three, rarely four together, half immerſed in the under ſide of the frond, and as each burſts by a longitudinal fiſſure, they all together have exactly the appearance of a ſingle capſule, of three cells, and three valves, the partitions ſeeming to originate from the centre of each valve. Traces of a jointed ring appear on ſome of the valves only, and rather reſemble the corrugations of thoſe ferns termed *ſpuriouſly annulated*. Several other ſpecies, ſtrictly allied to the original one in habit and appearance, ſo as to be at firſt ſight ſcarcely diſtinguiſhable from it, have been found in New Holland, and have been defined by Dr. Swartz and Mr. Brown. In theſe the capſules are not immerſed in the leaf, though each ſeries ſtands in a ſlight depreſſion. In *G. dicarpa* of Brown there are only two together; in others three, four, or even ſix. Theſe new diſcovered ſpecies evince the propriety of Mr. Brown's meaſure, of reducing the *Mertenſia* of Willdenow and Swartz to *Gleichenia*, as their fructifications exactly agree. *Dicranopteris* of Bernhardi does not in our opinion ſo well aſſort with them, having an irregular accumulation of ſtalked capſules in each dot, though its habit is preciſely that of *Mertenſia*. Mr. Brown, having examined theſe ferns alive, determines them to be furniſhed with a complete, ſtriated, tranſverſe, rarely oblique, ring.

This genus naturally divides itſelf into two ſections. The original *Gleicheniæ*, of which there are five ſpecies, have the ultimate branches of their repeatedly forked ſtem pinnate, their leaflets or *pinnæ* deeply pinnatifid, with ſhort, triangular, or rounded ſegments, each ſegment bearing a ſingle dot or ſeries of capſules. The *Mertenſiæ* have their ultimate branches deeply pinnatifid, the ſegments linear, with a row of numerous dots on each ſide of the midrib of each ſegment, eſpecially at its lower half. Of theſe we are acquainted with five or ſix ſpecies, all natives of the Eaſt or Weſt Indies, or of New Holland and its neighbourhood.

GLEICHENSTEIN, in *Geography*, a town and caſtle of Germany, in the territory of Eichsfeld; ſeven miles S.E. of Heiligenſtadt.

GLEINSTOLLEN, a town of the duchy of Stiria; 14 miles S.E. of Voitſberg.

GLEISS, a town of Switzerland, in the Valais; 26 miles E. of Sion.

GLEIWITZ, or GLIWICE, a town of Sileſia, in the principality of Oppeln; 20 miles N.E. of Ratiſbon. N. lat. 50° 17′. E. long. 18° 35′.

GLEN RIVER, is a river of Lincolnſhire, which riſes near Ropſley, and purſues a courſe nearly S.S.E. to Bracebrough, when, turning ſuddenly N.E., it paſſes to Kates bridge and through the Fens, by Surfleet, to the ſea at Foſdyke Waſh; for the greater part of its courſe through the Fens this river is navigable for barges, a circumſtance which was over-looked in compiling the alphabetical liſt of inland navigations in our article CANAL. The ſmall river or drain called the Bourne, which branches from the Glen and proceeds up to Bourne town, is alſo navigable for ſome diſtance upwards. The South Forty-foot navigable drain commences very near to this river, below the mouth of the Bourne, and proceeds by a circuitous route to Boſton. See SOUTH FORTY-FOOT.

GLENAA, a mountain in the county of Kerry, Ireland. See KILLARNEY.

GLENAN ISLANDS, a cluſter of ſmall iſlands in the Atlantic, near the coaſt of France. N. lat. 47° 43′. W. long. 3° 55′.

GLENARM, a poſt town of the county of Antrim, Ireland, on the eaſt coaſt of it, adjoining which is Glenarm caſtle, the ſeat of the counteſs of Antrim. The town is pleaſantly ſituated on the ſea-ſhore, near the bay of the ſame name. It is 104 miles N. from Dublin, and 24 N. from Belfaſt.

GLENAVY, a poſt-town of the county of Antrim, Ireland, ſituated near the eaſtern border of Lough Neagh. It is 77 miles N. from Dublin on the road to Antrim.

GLENCOE, a vale of Scotland, in the county of Argyle, near Loch Leven, where, in the year 1691, the inhabitants were maſſacred contrary to the faith of a royal proclamation; 17 miles N. of Inverary.

GLENDALOUGH, GLANDELOUGH, or *Glendalloch*, commonly called the *Seven Churches*, an intereſting object to travellers in the county of Wicklow, Ireland, 22 miles S. from Dublin, and about ſeven or eight miles weſt from Rathdrum. Its name is derived, according to Mr. Ledwich, from its being ſituated in a valley with lakes, from *glen*, a valley, and *loch*, a lake. That this was the true origin of the name ſeems to be confirmed by Hoveden, who was chaplain to Henry II., and who calls it equivalently in Latin, Epiſcopatus Biſtagnenſis, the biſhopric of the two lakes. Glendalough is ſurrounded on all ſides, except to the eaſt, by ſtupendous mountains, whoſe vaſt perpendicular height throws a gloom on the vale below, well ſuited to inſpire religious dread. From theſe, many mountain-ſtreams fall into the valley, and, forming a junction, aſſume the name of Avonmore. One of theſe ſtreams, called St. Kevin's keeve, is ſtill an object of ſuperſtition; weak and ſickly children being dipped in it every Sunday and Thurſday before ſun-riſe, and on the third of June, which is St. Kevin's day. The two lakes in the vale are divided from each other by a rich meadow; the reſt of the ſoil is ſo rocky as to be incapable of tillage by the plough. The names of the adjoining mountains, in which the word *Derry* often occurs, are ſuppoſed to denote that they were formerly covered with wood; at preſent they have only brown heath, or more ſable peat. Between the cathedral and upper lake is a group of thorns of great ſize; and near the cathedral the trunk of an aged yew, which meaſures three yards in diameter. From the remains of walls above, and the traces of foundations below the ſurface of the earth, the town is ſuppoſed to have been once pretty large, but the only ſtreet appearing is the road leading from the market place into the county of Kildare. It is in good preſervation, being paved with ſtones placed edgewiſe, and ten feet in breadth. There are ſeven churches of conſiderable antiquity, and ſome chapels which appear to be of later conſtruction. St. Kevin was the patron ſaint, and his name conſequently is given to many of the ſurrounding objects. He is ſaid to have founded the town or monaſtery in the ſixth century; but Ledwich attributes the erection to the Oſtmen, who infeſted Ireland, in the ninth century. Some figures in a chapel, containing the tomb of St. Kevin, furniſh ſome plauſible arguments in ſupport of this opinion. There are two round towers at Glendalough, both of which are adjoining churches, but neither the cathedral nor abbey has ſuch an addition, though if a belfry were the object of theſe buildings, the preference would probably have been given to them. Theſe towers were alſo, in Mr. Ledwich's opinion, the work of the Oſtmen. The arguments for and againſt this opinion will be conſidered under the article ROUND TOWERS. A monaſtery having been founded here, and the ſuppoſed miracles of St. Kevin having been proclaimed, numbers flocked to his ſhrine; as Girald Cambrenſis ſays, in what had been a barren wilderneſs, were to be found, after a few years, not only churches and good houſes, but much wealth. According to the Iriſh annals, the town thus founded was often plundered by the piratical freebooters of the north, who, as they ſubſiſted ſolely by depredations, without reluctance, frequently pillaged their own countrymen. In 1162, Laurence O'Toole, afterwards archbiſhop of Dublin, was elected abbot; and in a few years after earl Strongbow granted the abbey and parſonage to Thomas, the nephew of Laurence. The charter is one of the moſt valuable and ancient in Ireland, as it preſerves the poſſeſſions, privileges, and immunities of the abbey. Previous to this, Glendalough had alſo had a biſhop; but, in 1152, Cardinal Paparon endeavoured to unite it to the ſee of Dublin. This was reſiſted, and, in 1179, pope Alexander III. confirmed the city to its biſhop, ſaving the rights of the abbot. A letter, written in 1214, is quoted by Ledwich, to ſhew that Glendalough was at that time become a neſt of thieves and robbers. In the reign of king John, the ſee was united to that of Dublin; but the ſect of the O'Tooles, who were very powerful, kept it, in ſome degree, independent until 1497, when the biſhop formally ſurrendered his right and claim in the Chapter-houſe of St. Patrick, Dublin. The Seven Churches, when approached by the bridge of Derrybawn, form a very pictureſque and pleaſing ſcene. The bridge is thrown over the Avonmore, and is compoſed of three elliptic arches. Derrybawn, covered to a great extent with an oak coppice on one ſide, and the huge broccagh on the other, confines the view up the river to the valley; at the end of which the great round tower, and the other ruins, appear to great advantage. As the new military road has made Glendalough eaſily acceſſible, it is frequently viſited by travellers. Ledwich's Antiquities.

GLENE, Γληνη, properly ſignifies the cavity or ſocket of the eye.

Glene is more frequently uſed by anatomiſts for the ſhallower cavities of bones, into which ſome other bone is received and articulated.

By which it ſtands diſtinguiſhed from *cotyle* or *acetabulum*, which is a deeper cavity, intended by nature for the like purpoſe.

GLENEGAD Head, in *Geography*, a cape of Ireland, in the peninſula of Inis Lowen, county of Donegal. W. long. 7° 41′ from Greenwich, N. lat. 55° 20′.

GLENGARRIFF, a harbour of Ireland, in the county of Cork, on the north-eaſt part of Bantry-bay. The arbutus grows in this neighbourhood in great perfection.

GLENGARY, the name of a county in Upper Canada, bounded on the E. by the line which ſeparates Upper from Lower Canada; on the S. by the river St. Lawrence; and on the W. by the townſhip of Cornwall, running N. 24° W., until it interſects the Ottawa or Grand river, thence deſcending the ſaid river till it meets the fore-mentioned ſeparating line. Glengary county comprehends all the iſlands contiguous to it in the river St. Lawrence.

GLENICZA, a river of the duchy of Warſaw, which runs into the Obra, near Koſten.

GLENKEN'S Canal, is the parliamentary name of an inland navigation, made ſince the year 1802, in Kirkcudbright county in Scotland. See Canal.

GLENLUCE, a town of Scotland, in the county of Wigton, which ſprang from an abbey of Ciſtertians, founded in 1190, called "Vallis Lucis." It is ſituated at the northern extremity of a large bay to which it gives name; 18 miles W. of Wigton. N. lat. 54° 58′. W. long. 4° 27′. The bay extends on the S. coaſt of Scotland from the Mull of Galloway to Burrowhead. N. lat. 54° 50′. W. long. 4° 50′.

GLENMORE, a ſmall iſland on the W. coaſt of Scotland, at the mouth of Loch Suart. N. lat. 56° 38′.

GLENOID, in *Anatomy*, from γληνη, *the articular cavity of a bone*, and ειδος, *form*, a term applied to certain articular ſurfaces, particularly where the hollow is not deep.

GLERS, in *Geography*, a town of Germany, in the county of Tyrol; 21 miles W. of Bolzano.

GLESE, a river of Louiſiana, which runs into the Miſſiſippi, N. lat. 37° 15′. W. long. 90° 14′.

GLESUM, or Glæsum, in *Natural Hiſtory*, a name given by many of the ancients to the common yellow amber or ſuccinum. The word ſeems to have been originally German, and to have been adopted by the Romans in their conqueſts in that part of the world. They ſeem to have uſed the word in general for any tranſparent ſubſtance, and thence to have applied it to amber as a tranſparent ſtone. See Glass.

GLETCHERHORN, in *Geography*. See Jungfrau.

GLIANY, a town of Poland, in Galicia; 20 miles E. of Lemberg.

GLIESA, a town of Sweden, in Weſt Bothnia; 25 miles W.N.W. of Tornea.

GLIGVI, a town of Aſia, in Dageſtan; 90 miles N. of Teflis.

GLIKEON, a town of European Turkey, in the province of Epire; 26 miles W. of Arta.

GLIMS Holm, one of the ſmall Orkney iſlands, which affords paſtures; 2 miles S. of Pomona, between that and Barray.

GLIMMER, or Cat-silver, in *Mineralogy*, according to Dr. Woodward, "Method of Foſſils," p. 14, are names for *Mica*, which ſee. Gliſt, ſpangles, daze, and ſilver, are other names by which the miners and quarrymen deſignate the ſhining plates of this ſubſtance which they meet with diſperſed in the earths and ſtones in their works. The late Mr. William Martin obſerves, "Outlines," p. 141, "Glimmer is frequently diſperſed through the ſand-ſtones and clay, forming vegetable petrifactions, but never conſtitutes their whole ſubſtance." In Derbyſhire, it is not uncommon to find nodules, or round neſts or maſſes of mica, in thin and ſeparate plates, in the firſt, or millſtone grit, which fall out on expoſure, and leave ſpherical holes, a circumſtance which has, according to Mr. Farey, given riſe to rock-baſins or holes on the tops of large looſe blocks of ſtone where the water ſtands in many inſtances after rain, but not perpetually, as the vulgar opinion is. See Rock-Basins.

GLINA, in *Geography*, a river of Croatia, which runs into the Save; 12 miles W. of Patrinia.

GLINLOUGH, a lake of Ireland, in the northern part of the county of Leitrim, from which a ſmall river flows to Sligo bay.

GLINNINO, a town of Ruſſia, in the government of Novogorod, on the Mſta; 12 miles S.E. of Borovitchi.

GLINSK, a town of Ruſſia, in the government of Tchernigof, on the river Sula; 80 miles S.E. of Tchernigof.

GLINUS, in *Botany*, derives its name from γλινος or γλεῖνος, a word uſed by Theophraſtus, and denoting a kind of maple, though we cannot trace any ſimilitude between that tree and the little herbaceous plant, to which the name was applied by Loefling; but it was adopted by Linnæus. —Linn. Gen. 243. Schreb. 328. Loefl. Iter. 145. Willd. Sp. Pl. v. 2. 929. Mart. Mill. Dict. v. 2. Lamarck Dict. v. 2. 728. Gærtn. t. 130. Juſſ. 316.—Claſs and order, *Dodecandria Pentagynia*. Nat. Ord. *Caryophyllei*, Linn. *Ficoideæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five ovate, acute, concave leaves, coloured within, permanent, and downy. *Cor.* none; nectaries about five, reſembling narrow petals, ſhorter than the calyx, and unequally two or three-cleft. *Stam.* Filaments about fifteen, awl-ſhaped, flat, as long as the calyx; anthers incumbent, oblong, compreſſed, two-lobed. *Piſt.* Germen of five ſides; ſtyles five, ſhort; ſtigmas ſimple. *Peric.* Capſule ovate, with five cells, five ſides, and five valves. *Seeds* numerous, roundiſh, in a ſingle row at the baſe of the valves, tubercled, each attached by a long thread-like ſtalk.

Eſſ. Ch. Calyx five-cleft. Corolla none. Nectaries cloven briſtles. Capſule five-cornered, five-celled, five-valved, with many ſeeds.

1. G. *lotoides*. Linn. Sp. Pl. 663. Burm. Ind. 112. t. 36. f. 1. "Stem hairy. Leaves obovate."—Native of Spain, and found by Loefling in a gravelly ſoil near Talavera del Badajoz, alſo in a dried-up rivulet between Merida and Truxillo. *Root* annual. *Stems* procumbent, jointed, hairy. *Leaves* obovate, on foot-ſtalks. *Flowers* nearly ſeſſile, crowded together, ſometimes on very ſhort hairy ſtalks. A figure of this ſpecies is deſtined to appear in the *Flora Græca*, t. 472, from a drawing made at Smyrna, and from which it appears that what Gærtner conſidered as *petals*, are more probably *nectaries*, as not being external to the ſtamens; after all, they ought perhaps to be called

barren filaments. They ſeem, from the dried ſpecimens, to be ranged alternately with the real ſtamens.

2. G. *dictamnoides.* Willd. Sp. Pl. v. 2. 929. Pluk. Amal. 10. t. 356. f. 6.—“ Leaves round, hairy. Stem ſhrubby, proſtrate. Leaflets of the calyx lanceolate.”—Native of India. It ſeems doubtful whether G. *dictamnoides* be not merely a variety of *lotoides*; but as Willdenow ſtill keeps them ſeparate, on the authority of a dried ſpecimen, we have retained the ſpecies.

3. G. *ſetiflorus.* Willd. Sp. Pl. v. 2. 929. Vahl. Symb. 3. 64.—“ Leaves obovate, plaited. Stem ſhrubby. Leaflets of the calyx ovate.”—Native of inundated woods in Arabia Felix during the rainy ſeaſon. The whole plant is hoary, from very thick hairs, which are longer than in G. *lotoides*. This ſpecies was firſt deſcribed by Vahl, from Forſkal's ſpecimen which we have examined. The pubeſcence is beautifully ſtellated and very denſe.

Glinus, in *Ichthyology*, a name by which Bellonius and ſome other authors have called a ſmall ſea-fiſh, more commonly known by the name of the dracunculus.

GLIS. In the common acceptation of the word, this only ſignifies the dormouſe: but Linnæus has uſed *glires* in a larger ſenſe: and, in his Syſtem of Zoology, makes it the name of the fourth order of the mammalia claſs of animals. The characters of the creatures of this claſs are, that they have only two fore-teeth in each jaw; they have no *dentes canini*, or dog-teeth; and the feet have toes, and are formed for leaping when they run. The animals of this claſs are the ſeveral ſpecies of the *Hyſtrix*, *Cavia*, *Caſtor*, *Mus*, *Arctomys*, *Sciurus*, *Myoxus*, *Dipus*, *Lepus*, and *Hyrax*; which ſee reſpectively.

Glis, a name given to ſeveral ſpecies of *Myoxus*; of *Didelphis*; of *Mus*; and of *Arctomys*; which ſee reſpectively.

Glis *Volans*. See Vespertilo *Spaſma*.

GLISCHROMICTHES, in *Natural Hiſtory*, the name of a genus of compound earths. The word is derived from γλισχρος, *touch*, and μιχθεις, *mixed*. The bodies of this genus are loams compoſed of ſand and a more viſcid clay, and are of a tough and firm texture.

The earths of this genus are uſed in making bricks, and on ſome other occaſions; and are of ſeveral diſtinct ſpecies.

GLISSA, in *Ichthyology*, the name of a ſea-fiſh of the tunny kind, but of a perfectly ſmooth ſkin, and wholly free from ſcales. It uſually grows to the length of two cubits, and the thickneſs of a man's body: it is of a very round body, and has very rough jaws, but no diſtinct teeth; its tail is forked, but not ſo arched or lunated as that of the tunny; it lives in deep water, and is a fiſh of very delicate taſte. Geſner. De Piſc. p. 1158.

GLISSON, Francis, in *Biography*, was born at Rampiſham, in Dorſetſhire, in the year 1597, and educated at Caius college, Cambridge, of which he became a fellow, and in 1627 was incorporated M.A. in Oxford. He then applied himſelf to the ſtudy of phyſic, in which faculty he took his degree of doctor at Cambridge, and in that univerſity was made regius profeſſor of phyſic, which office he held about 40 years. He ſettled in London for the practice of his profeſſion, and was admitted a fellow of the College of Phyſicians in 1635. In 1639 he was choſen reader of anatomy in the college, and in that department acquired great reputation by his lectures “De Morbis Partium,” which he was particularly requeſted by his colleagues to make public. During the civil wars he retired to Colcheſter, where he practiſed with great credit in thoſe times of confuſion, and was in the town at its memorable ſiege by the parliamentary forces in 1648. He was one of that ſmall, but illuſtrious ſociety, who inſtituted a weekly meeting in London about the year 1645, for the purpoſe of promoting inquiries into natural and experimental philoſophy, which, after having removed to Oxford during the troubles, was augmented in London after the reſtoration, and became ultimately the Royal Society. He was afterwards ſeveral years preſident of the College of Phyſicians, and died in 1677, in the pariſh of St. Bride's, London, aged 80. Gliſſon left the following works: 1. “Tractatus de Rachitide, ſeu morbo puerili Rickets dicto,” firſt publiſhed in 1650; it went through ſeveral editions abroad, and two tranſlations into Engliſh the year after its publication, by Philip Armin, and Nicholas Culpepper. 2. “Anatome Hepatis, &c.” London, 1654; afterwards reprinted at Amſterdam and the Hague. This work contains a much more exact deſcription of the liver than had before appeared. The capſule of the *vena portarum* was ſuppoſed to be firſt diſcovered by him, and has ever ſince borne his name; but Walæus and Pecquet had ſeen it a ſhort time before, and he has only the merit of having firſt examined and deſcribed it with accuracy. Dr. Gliſſon's largeſt work is a metaphyſical piece, *viz.* 3. “Tractatus de Natura Subſtantiæ Energetica, ſeu de Vita Naturæ, ejuſque tribus primis Facultatibus,” Lond. 1672, in 4to., a profound and laborious performance, in the very depths of the Ariſtotelic philoſophy, with all its numerous diviſions, and an extraordinary effort of the underſtanding in a man of an advanced age.—4. His laſt publication, “Tractatus de Ventriculo et Inteſtinis, cui præmittitur alius de partibus continentibus in genere, et in ſpecie, de iis Abdominis,” Lond. 1676, 4to., Amſt. 1677, 12mo, contains every thing at that time known concerning the alimentary canal, arranged in a clear manner, with various new obſervations. In a word, Gliſſon was exceeded in judgment and accuracy by none of that group of Engliſh anatomiſts, who followed the ſteps of Harvey with great ardour and ſucceſs; inſomuch that Boerhaave terms him “omnium anatomicorum exactiſſimus,” and Haller ſpeaks in praiſe of all his writings. Aikin Biog. Mem. of Med. Eloy. Dict. Hiſt.

GLISTER. See Clyster.

GLITNESS, in *Geography*, one of the ſmaller Shetland iſlands, on the E. coaſt of Shetland; 11 miles N. of Lerwick. N. lat. 60° 22′. W. long. 1° 16′.

GLIUBEN, a town of European Turkey, in Dalmatia; 18 miles S.E. of Moſtar.

GLIZADE, in *Fencing*, is an operation performed by dextrouſly making your blade ſlip along that of your adverſary by a movement of the wriſt, and a quick forward extenſion of the arm, without deviating from the line of direction. This is a ſimple, and at the ſame time a maſterly movement in fencing.

GLOBBA, in *Botany*, a Malay name adopted by Rumphius and Linnæus, under which, however, they have included a very heterogeneous aſſemblage of ſpecies. We ſhall ſpeak only of ſuch as agree in generic character with the original one, ſeen and deſcribed by Linnæus, and preſerved in his herbarium. Linn. Mant. 2. 143. Schreb. 25. Willd. Sp. Pl. v. 1. 153. Mart. Mill. Dict. v. 2. Roſcoe in Tr. of Linn. Soc. v. 8. 355. t. 20. f. 13. Ait. Hort. Kew. ed. 2. v. 1. 9. Juſſ. 63. Lamarck Dict. v. 2. 729.—Claſs and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, tubular, permanent; its border three-lobed. *Cor.* of one petal; tube long, cylindrical, ſlender; outer limb in three, nearly equal, ovate, ſpreading lobes; inner of two ſimilar lobes, and a central, vertical, prominent lip, cloven at each extremity. *Stam.* Filament one, prominent, long, linear, channelled, dilated at its ſummit; anther oblong, of two diſtinct parallel lobes, attached by its back to the dilated part of the filament. *Piſt.* Germen inferior, roundiſh; ſtyle thread-ſhaped, the length of the filament and embraced by it; ſtigma obtuſe. *Peric.* Capſule roundiſh, of three cells and three valves. *Seeds* numerous.

Eſſ. Ch. Anther in two parts. Filament elongated, incurved, bearing a lobed appendage. Style thread-ſhaped, embraced by the anther. Corolla with three outer lobes and three inner, the middlemoſt vertical and cloven.

1. G. *marantina.* Linn. Mant. 2. 170. Sm. Exot. Bot. v. 2. 85. t. 103. (Colebrookia bulbifera; Donn Cant. 1.)—Appendage of the filament four-lobed, divaricated, terminal. Spike not taller than the leaves. Bracteas elliptical, broad, longer than the calyx.—Native of Bengal, from whence it was ſent by Dr. Roxburgh to the late lady Amelia Hume in 1800. It flowers in the ſtove in July and Auguſt. *Root* perennial, tuberous. *Stems* ſeveral, herbaceous, about two feet high, ſimple, leafy. *Leaves* elliptical, acute, entire, with one rib and numerous parallel ſimple veins; ſmooth above; ſoft and finely downy beneath; their footſtalks long, ſheathing, bearded at the top, which is extended upwards into a pair of rounded auricles. *Spike* terminal, ſolitary, ſimple, erect, more or leſs lax, about as tall as the leaves, or rather under that height. *Bracteas* alternate, ſeſſile, elliptical, broad, concave, many-ribbed, ſomewhat downy, minutely dotted; the lower ones each bearing one ovate bulb; the upper ones a cluſter of ſeveral *flowers*, each of which is accompanied by its own ſmaller bractea. Theſe *flowers* are very tranſient, ſlender, orange-coloured, with a deeper ſpot in the centre of the lip.

2. G. *racemoſa.* Sm. Exot. Bot. v. 2. 115. t. 117. (Deoſara; of the inhabitants of Nepal.)—Appendage of the filament arrow-ſhaped, narrower than the anther. Cluſter elongated, cylindrical. Bracteas ſhorter than the calyx, deciduous.—Gathered by Dr. F. Buchanan in the woods of Upper Nepal, flowering in June. Habit of the laſt, but taller, with larger more pointed *leaves.* The *infloreſcence* is much more ſtriking, and conſiſts of a long terminal *racemus* of numerous orange-coloured *flowers*, which are twice the ſize of the former, and eſſentially diſtinguiſhed from that by the arrow-ſhaped form of the appendage to their filament, which does not extend beyond the anther, except at its rounded termination.

3. G. *verſicolor.* Sm. Exot. Bot. v. 2. 116. t. 117, *a, b, c,* (Hura Siamenſium; Kœnig in Retz. Obſ. faſc. 3. 49.)—Appendage of the filament four-lobed, divaricated. Cluſter ſomewhat corymboſe. Bracteas ſhorter than the calyx. Lip towards the middle of the filament.—Found by Kœnig plentifully in graſſy ſhady parts of the iſland called Young Ceylon, in the Eaſt Indies. The *cluſter* of flowers is ſhorter and more corymboſe than in *G. racemoſa*, and the corolla is variegated with orange, white, and different ſhades of violet. The appendage of the filament nearly reſembles that of *G. marantina*, but the ſituation of the lip, thruſt, as it were, half way up the filament, above the other lobes of the corolla, is altogether peculiar. For this, however, we depend on a drawing made by Mr. Sidney Parkinſon, and communicated by ſir Joſeph Banks, of the accuracy of which we have no reaſon to doubt. Kœnig mentions a more dwarf variety, found near the town of Malacca. Can this be what has lately been introduced into the ſtoves about London by Dr. Roxburgh, and which we have ſeen and examined at ſir Abraham Hume's, and at Meſſrs. Lee and Kennedy's, flowering in June 1810? It is figured in Curtis's Magazine, t. 1320, where Dr. Sims has, we think, juſtly made this pretty plant a new genus, by the name of *Mantiſia ſaltatoria.* It differs from *Globba* in having a radical, not terminal, infloreſcence, which, as far as we know, is an infallible indication of a generic difference in this natural order, and therefore the flower affords, as was neceſſarily to be expected, clear eſſential characters of diſtinction, in the two long linear appendages to the lower part of the filament, which ſupply the place of two of the inner ſegments of the corolla, while the lip, which makes the third, is not bifid at its upper extremity. The large purple *bracteas*, and the branched *flower-ſtalk*, are alſo remarkable. S.

GLOBE, in *Geometry*, a round or ſpherical body, more uſually called a *ſphere;* which ſee.

The earth and water together are ſuppoſed to form a globe; hence called the terraqueous globe.

The planets, both primary and ſecondary, are ſuppoſed, as well as our earth, to be ſolid globes.

The earth is, in a particular ſenſe, called the globe, or globe of earth; though it is now well known that this is not its true figure. See *Figure of the* EARTH.

GLOBE, *Reſiſtance of a.* See RESISTANCE.

GLOBE is more particularly uſed for an artificial ſphere of metal, plaſter, paper, or ſome other matter; on whoſe convex ſurface is drawn a map, or repreſentation, either of the earth or heavens, with the ſeveral circles conceived thereon.

GLOBES are of two kinds, *terreſtrial* and *celeſtial:* each of very conſiderable uſe, the one in aſtronomy, and the other in geography, to perform many of the operations thereof in an eaſy, ſenſible manner, ſo as to be conceived without any knowledge of the mathematical grounds of thoſe arts.

The fundamental parts, common to both globes, are an axis, repreſenting that of the world, and a ſpherical ſhell or cover, which makes the body of the globe, on whoſe external ſurface the repreſentation is drawn.

Globes, we have obſerved, are made of divers materials, *viz.* ſilver, braſs, paper, plaſter, &c. Thoſe commonly uſed are of plaſter and paper; the conſtruction whereof is as follows.

GLOBES, *Conſtruction of.* A wooden axis is provided, ſomewhat leſs than the intended diameter of the globe; and into the extremes hereof two iron wires are driven for poles: this axis is to be the beam or baſis of the whole ſtructure.

On the axis are applied two ſpherical, or rather hemi-ſpherical caps, formed on a kind of wooden mould or block. Theſe caps conſiſt of paſteboard and paper, laid, one lay after another, on the mould, to the thickneſs of a crown piece; after which, having ſtood to dry and embody, making an inciſion along the middle, the two caps, thus parted, are ſlipped off the mould.

They remain now to be applied on the poles of the axis, as before they were on thoſe of the mould; and to fix them in their new place, the two edges are ſown together with packthread, &c.

The rudiments of the globe thus laid, they proceed to ſtrengthen and make it ſmooth and regular. In order to this, the two poles are haſped in a metalline ſemi-circle of the ſize intended; and a kind of plaſter, made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper ſurface. In proportion as the plaſter is applied, the ball is turned round in the ſemi-circle, the edge whereof pares off whatever is ſuperfluous, and beyond the due dimenſion, leaving the reſt adhering in places that are ſhort of it.

After ſuch application of plaſter, the ball ſtands to dry; which done, it is put again in the ſemi-circle, and freſh matter applied: thus they continue alternately to apply the compoſition, and dry it, till ſuch time as the ball everywhere accurately touches the ſemi-circle; in which ſtate it is perfectly ſmooth, regular, firm, &c.

The ball thus finiſhed, it remains to paſte the map or deſcription thereon: in order to this, the map is projected in ſeveral gores or guſſets, all which join accurately on the ſpherical ſurface, and together cover the whole ball. To direct the application of theſe gores, lines are drawn by a ſemi-circle on the ſurface of the ball, dividing it into a number of equal parts correſponding to thoſe of the gores, and ſubdividing thoſe again anſwerably to the lines and diviſions of the gores.

The papers thus paſted on, there remains nothing but to colour and illuminate the globe, and to varniſh it, the better to reſiſt duſt, moiſture, &c.

The globe itſelf thus finiſhed, they hang it in a braſs meridian, with an hour circle and quadrant of altitude, and thus fit it into a wooden horizon.

GLOBES, *Deſcription of the.* The things common to both globes are either delineated on the ſurface, or added as appendages without it.

Without the ſurface are, 1. The two poles whereon the globe is turned, repreſenting thoſe of the world. (See POLE.) 2. The brazen meridian, which is divided into degrees, and paſſes through the poles. 3. The wooden horizon, whoſe upper ſide repreſents the horizon, and is divided into ſeveral circles; the innermoſt whereof contains the twelve ſigns of the zodiac, ſubdivided into their degrees; the next the Julian; and the third the Gregorian calendar; without ſide of all theſe, are drawn the points of the winds. 4. A braſs quadrant of altitude, divided into 90 degrees, to be faſtened on the meridian at the diſtance of 90 degrees from the horizon. 5. The hour-circles, divided into twice twelve hours, and fitted on the meridian, round the poles, which carry an index pointing to the hour. A mariner's compaſs is ſometimes added on the bottom of the frame, and ſometimes a ſemi-circle of poſition.

On the ſurface are delineated, 1. The equinoctial line, divided into 360 degrees, commencing from the vernal interſections. 2. The ecliptic, divided into twelve ſigns, and theſe ſubdivided into degrees. 3. The zodiac. 4. The two tropics. And, 5. The polar circles. All which ſee under their proper articles.

What elſe belongs to globes, either as to conſtruction or deſcription, is different as the globe is either *celeſtial* or *terreſtrial.*

Our common globes, though inſtructive inſtruments for explaining the firſt rudiments of geography and the ſpherical doctrine of aſtronomy, yet labour under ſeveral defects; as they do not ſhew how the phenomena, illuſtrated by them, ariſe from the motion of the earth, which is the principal thing beginners eſpecially ſhould have in view, and as they are only formed for the preſent age, and do not ſerve the purpoſes of chronology and hiſtory, which they might be made to do, if the poles, whereon they turn, were contrived to move in a circle round thoſe of the ecliptic, according to its preſent obliquity.

Mr. John Senex, F.R.S. invented a contrivance for remedying theſe defects, by fixing the poles of the diurnal motion to two ſhoulders or arms of braſs, at the diſtance of 23°½ from the poles of the ecliptic. Theſe ſhoulders are ſtrongly faſtened at the other end to an iron axis, which paſſes through the poles of the ecliptic, and is made to move round with a very ſtiff motion; ſo that when it is adjuſted to any point of the ecliptic, which the equator is made to interſect, the diurnal motion of the globe on its axis will not be able to diſturb it. When it is to be adjuſted for any time, paſt or future, one of the brazen ſhoulders is brought under the meridian, and held faſt to it with one hand, whilſt the globe is turned about with the other, ſo that the point of the ecliptic, which the equator is to interſect, may paſs under 0 degree of the brazen meridian: then holding a pencil to that point, and turning the globe about, it will deſcribe the equator according to its poſition at the time required; and transferring the pencil to 23°½, and 66½ on the brazen meridian, the tropics and polar circles will be ſo deſcribed for the ſame time. By this contrivance, the celeſtial globe may be ſo adjuſted, as to exhibit not only the riſings and ſettings of the ſtars, in all ages and in all latitudes, but likewiſe the other phenomena that depend upon the motion of the diurnal axis round the annual axis. Senex's celeſtial globes, eſpecially the two greateſt, of ſeventeen and twenty-eight inches in diameter, have been conſtructed on this principle: ſo that by means of, a nut and ſcrew, the pole of the equator is made to revolve about the pole of the ecliptic. Phil. Tranſ. Nº 447, p. 201. 203. or Martyn's Abr. vol. viii. p. 217. and Nº 493, art. 18. in Phil. Tranſ. vol. xlvi. p. 290.

Mr. Joſeph Harris, late aſſay-maſter of the mint, contrived to remedy the former of the defects above-mentioned, by placing two horary circles under the meridian, one at each pole; theſe circles are fixed tight between two braſs collars placed about the axis, ſo that when the globe is turned, they are carried round with it, the meridian ſerving as an index to cut the horary diviſions. The globe, in this ſtate, ſerves readily for ſolving problems in north and ſouth latitudes, and alſo in places near the equator; whereas, in the common conſtruction, the axis and horary circle prevent the braſs meridian from being moveable quite round in the horizon. This globe is alſo adapted for ſhewing how the viciſſitudes of day and night, and the alteration of their lengths, are really occaſioned by the motion of the earth; for this purpoſe, he divides the braſs meridian, at one of the poles, into months and days, according to the ſun's declination, reckoning from the pole. Therefore, by bringing the day of the month to the horizon, and rectifying the globe according to the time of the day, the horizon will repreſent the circle ſeparating light and darkneſs, and the upper half of the globe the illuminated hemiſphere, the ſun being in the zenith.

Mr. Harris alſo gives an account of a cheap machine for ſhewing how the annual motion of the earth in its orbit cauſes the change of the ſun's declination, without the great expence of an orrery. Phil. Tranſ. Nº 456, p. 321, &c. or Martyn's Abr. vol. viii. p. 352.

The late Mr. George Adams, mathematical inſtrument maker to his majeſty, has made ſome uſeful improvements in the conſtruction of the globes. His globes, like others, are ſuſpended at their poles in a ſtrong braſs circle, and turn therein upon two iron pins, which are the axis. They have beſides a thin braſs ſemi-circle, moveable about the poles, with a ſmall, thin, ſliding circle upon it. On the terreſtrial globe, the thin braſs ſemi-circle is a moveable meridian, and its ſmall ſliding circle the viſible horizon of any particular place to which it is ſet. On the celeſtial globe, the ſemi-circle is a moveable circle of declination, and its ſmall annexed circle an artificial ſun or planet. Each globe hath a braſs wire circle, placed at the limits of the twilight, which, together with the globe, is ſet in a wooden frame, ſupported by a neat pillar and claw, with a magnetic needle at its baſe. On the terreſtrial globe the diviſion of the earth into land and water is laid down from the lateſt diſcoveries; there are alſo many additional circles, as well as the rhumb-lines, for ſolving all the neceſſary geographical and nautical problems. On the celeſtial globe, all the ſouthern conſtellations, lately obſerved at the Cape of Good Hope by M. de la Caille, and all the ſtars in Mr. Flamſteed's Britiſh Catalogue, are accurately laid down and marked with Greek and Roman letters of reference, in imitation of Bayer. Upon each ſide of the ecliptic are drawn eight parallel circles, at the diſtance of one degree from each other, including the zodiac; and theſe are croſſed at right angles with ſegments of great circles at every fifth degree of the ecliptic, for the more readily noting the place of the moon, or of any planet upon the globe. The author has alſo inſerted, from Ulugh Beigh, printed at Oxford in 1665, the manſions of the Moon of the Arabian Aſtronomers, ſo called, becauſe they obſerved the moon to be in or near one of theſe every night during her monthly courſe round the earth, to each of which the Arabian characters are fixed. On the ſtrong braſs circle of the terreſtrial globe, and about $23^\circ\frac{1}{2}$ on each ſide of the north pole, the days of each month are laid down according to the ſun's declination; and this braſs circle is ſo contrived, that the globe may be placed with the north and ſouth poles in the plane of the horizon, and with the ſouth pole elevated above it. The equator, on the ſurface of either globe, ſerves the purpoſe of the horary circle, by means of a ſemi-circular wire placed in the plane of the equator, carrying two indices, one of which is occaſionally to be uſed to point out the time. For a farther account of theſe globes, with the method of uſing them, the reader may conſult Adams's Treatiſe on their Conſtruction and Uſe, &c. 1769.

Globe, *Celeſtial*, is an artificial ſphere, on whoſe convex ſurface the fixed ſtars are laid down, at proportionable diſtances, together with the principal circles of the ſphere.

The ſurface of the celeſtial globe may be eſteemed a juſt repreſentation of the concave expanſe of the heavens, notwithſtanding its convexity; for if the eye were placed in the centre of it, and the globe made of glaſs, the ſtars that are drawn upon it would appear in a concave ſurface, exactly correſponding to thoſe in the heavens. The uſe of theſe globes is to exhibit the phenomena of the motions of the ſun and ſtars, in an eaſy and obvious manner; which, though ſomewhat inaccurate, is yet exact enough for the common uſes of life, and may ſave the trouble of trigonometrical calculations.

To exhibit the ſtars, circles, &c. on the ſurface of a given ſphere or ball, and fit for the uſes of aſtronomy.—1. Aſſume any two points diametrically oppoſite to each other, as P and Q (*Plate* XIV. *Aſtronomy, fig.* 117.) and in theſe fix up axes, P A and Q C, for the ball to turn round on. The points P and Q, or A and C, will exhibit the poles of the world.

2. Divide a brazen circle A B C D into four quadrants, A E, E C, C F, and F D; and ſubdivide each quadrant into 90 degrees, numbered from the points E and F, towards the poles A and C.

3. Incloſe the globe in this circle, as in a meridian, at the points A and C, ſo as it may freely turn therein.

4. Apply a ſtyle or pin to the ſurface of the globe, in the firſt degree of the meridian, and turn the ball round; by this means will a circle be deſcribed on the ſurface, repreſenting the equator to be divided into degrees.

5. From the pole of the world P towards M, and from the other pole C towards N, number $23\frac{1}{2}$ degrees; the points M and N will be the poles of the ecliptic.

6. Apply a ſtyle to the meridian, in the point M, and turn the globe round; by this rotation will the arctic polar circle be deſcribed: and after the ſame manner is the antarctic polar to be deſcribed about the point N.

7. Number $23\frac{1}{2}$ deg. from the equator towards the poles P and Q, and note the points H and I; then applying a ſtyle to the meridian, as before, two circles will be deſcribed parallel to the equator, whereof that drawn through H will be the tropic of Cancer, and the other through I the tropic of Capricorn.

8. Hang the globe within the meridian, in the poles of the ecliptic, as before in the poles of the world; and applying a ſtyle to E, turn it round: by this means will the ecliptic be delineated, which remains to be divided into twelve ſigns; and each of theſe, again, divided into thirty degrees.

9. While the globe remains thus ſuſpended, bring the degree of longitude of any ſtar under the meridian; and in the meridian, number as many degrees towards the pole as is the degree of latitude of the place: the point of interſection is the place of that ſtar on the ſurface of the globe. After the like manner may the place of the ſtar be determined from the right aſcenſion and declination given, the globe being ſuppoſed ſuſpended from the poles of the world, or the equator.

10. All the ſtars of a conſtellation thus laid down, the figure of the conſtellation is to be deſigned; after which it may either be coloured or engraven.

11. Place the globe with the meridian, in a wooden frame or horizon, D B L, ſupported on four feet, in ſuch manner as to be divided thereby into two hemiſpheres, and that the pole A may be raiſed or depreſſed at pleaſure.

12. On the limb or edge of the horizon deſcribe a circle, which divide into 360 degrees, and inſert the calendars and winds.

13. Laſtly, To the pole A fit a brazen circle, divided into twenty-four horary parts, and numbered twice twelve, ſo that the line of diviſion of XII. may be in the plane of the meridian, on either ſide the pole; and on the pole itſelf apply an index, to turn round with the globe. See *Horary* Circle. Thus is the globe complete.

It may be here obſerved, that as the longitude of the ſtars is continually increaſing, a common globe does not remain of perpetual uſe: but the increaſe in ſeventy-two years only amounting to a degree, the whole will make no conſiderable error in a hundred years; the deſign of a globe being only to repreſent things ſomething near the truth.

Globe, *to make a celeſtial.* This method is that the moſt frequently uſed; and we only premiſed the former as being the moſt eaſily conceived, and leading more naturally to this.

1. From the given diameter of the globe, find a right line A B, *fig.* 118. equal to the circumference of a great circle, and divide it into twelve equal parts.

2. Through the ſeveral points of diviſion, 1, 2, 3, 4, &c. with the interval of ten of them, deſcribe arches, mutually interſecting each other in D and E: theſe figures or pieces, duly paſted or joined together, will make the whole ſurface of the globe.

3. Divide each part of the right line A B into thirty equal parts, ſo that the whole line A B, repreſenting the periphery of the equator, may be divided into 360 degrees.

4. From the poles D and E, *fig.* 119. with the interval of $23\frac{1}{2}$ deg. deſcribe arches *a, b;* theſe will be twelve parts of the polar circles.

5. After the like manner, from the ſame poles D and E, with the interval of $66\frac{1}{2}$ deg. reckoned from the equator,

deſcribe arches *c*, *d*; theſe will be twelfth parts of the tropics.

6. Through the degree of the equator *e*, correſponding to the right aſcenſion of any given ſtar, and the poles D and E, draw an arch of the circle, and taking in the compaſſes the complement of the declination from the pole D, deſcribe an arch interſecting it in *i*; this point *i* will be the place of that ſtar.

7. All the ſtars of a conſtellation being thus laid down, the figure of the conſtellation is to be drawn according to Bayer, Hevelius, or Flamſteed.

8. Laſtly, after the ſame manner are the declinations and right aſcenſions of each degree of the ecliptic *d g* to be determined.

9. The ſurface of the globe thus projected on a plane is to be engraven on copper, to ſave the trouble of doing this over again for each globe.

10. A ball, in the mean time, is to be prepared of paper, plaſter, &c. after the manner above directed, and of the intended diameter of the globe: on this, by means of a ſemi-circle and ſtyle, is the equator to be drawn: and through every 30th degree a meridian. The ball thus divided into twelve parts, correſponding to the ſegments before projected, they are to be cut from the printed paper, and paſted on the ball.

11. Nothing now remains but to hang the globe, as before, in a brazen meridian and wooden horizon; to which may be added a quadrant of altitude H I, *fig.* 120. made of braſs, and divided in the ſame manner as the ecliptic and equator.

If the declinations and right aſcenſions of the ſtars be not given, but their longitudes and latitudes in lieu thereof, the ſurface of the globe is to be projected after the ſame manner as before: except that, in this caſe, D and E, *fig.* 121. are the poles of the ecliptic, and *f h* the ecliptic itſelf; and that the polar circles and tropics, with the equator *g d*, and the parallels thereof, are to be determined from their declinations.

One of the fulleſt catalogues of the ſtars is that of Mr. Flamſteed; wherein the right aſcenſions and declinations, as well as the longitudes, latitudes, &c. are every where expreſſed.

GLOBE, *uſe of the celeſtial.* The uſe of this inſtrument is very extenſive; there being ſcarcely any thing in the ſpherical aſtronomy but may be exhibited thereby.

The principal points are contained in the following problems, with their ſolution; which will let the reader enough into the nature and reaſon of this noble inſtrument, to apply it, of his own accord, in any other caſes.

To find the right aſcenſion and declination of a ſtar, repreſented on the ſurface of the globe.—Bring the ſtar to the graduated ſide of the brazen meridian: then the number of degrees intercepted between the equator, and the point on the meridian cut by the ſtar, gives its declination; and the degree of the equator which comes under the meridian, together with the ſtar, is its right aſcenſion.

To find the longitude and latitude of a ſtar.—Apply the centre of the quadrant of altitude over the pole of the ecliptic in the ſame hemiſphere with the ſtar, and bring its graduated edge to the ſtar: the degree on the quadrant cut by the ſtar is its latitude, reckoned from the ecliptic; and the degree of the ecliptic cut by the quadrant its longitude.

To find the ſun's place in the ecliptic.—Seek the day of the month in the proper calendar on the horizon, and againſt the day in the circle of ſigns is the ſign and degree the ſun is in for that day; this done, find the ſame ſign upon the ecliptic, on the ſurface of the globe; this is the ſun's place for that day.

To find the declination of the ſun.—The ſun's place for the day given being brought to the meridian, the degrees of the meridian intercepted between the equinoctial and that place, are the ſun's declination for that day at noon.

To find the place of a planet, with its right aſcenſion and declination; its longitude and latitude for the time being given.—Apply the centre of the quadrant of altitude on the pole of the ecliptic (the pole, we mean, of the ſame denomination with the latitude), and bring it to the given longitude in the ecliptic: this point is the planet's place; and bringing it to the meridian, its right aſcenſion and declination will be found, as already ſhewn of a ſtar.

To rectify the globe, or adjuſt it to the place, &c. ſo as it may repreſent the preſent ſtate or ſituation of the heavens.—1. If the place be in north latitude, raiſe the north pole above the horizon; if in ſouth, raiſe the ſouth pole; till the arch intercepted between the pole and horizon be equal to the given elevation of the pole. 2. Fix the quadrant of altitude on the zenith, *i. e.* on the latitude of the place. 3. By means of a compaſs or meridian line, place the globe in ſuch a manner as that the brazen meridian may be in the plane of the terreſtrial meridian. 4. Bring the degree of the ecliptic the ſun is in to the meridian, and ſet the horary index to twelve; thus will the globe exhibit the face of the heavens for the noon of that day. 5. Turn the globe till the index come to any other given hour: thus will it ſhew the face of the heavens for that time.

To know all the ſtars and planets by means of the globe.—1. Adjuſt the globe to the ſtate of the heavens for that time. 2. Look on the globe for ſome one ſtar which you know, *e. gr.* the middlemoſt ſtar in the tail of the Great Bear. 3. Obſerve the poſitions of the other more conſpicuous ſtars in the ſame conſtellation; and by transferring the eye from the globe to the heavens, you will eaſily note the ſame there. 4. After the ſame manner may you proceed from this to the neighbouring conſtellations, till you have learned them all.

If the planets be repreſented on the globe, after the manner above deſcribed, by comparing them with the neighbouring ſtars you will likewiſe know the planets.

To find the ſun's oblique aſcenſion, his eaſtern amplitude, and azimuth, with the time of riſing.—1. Rectify the globe for the hour of twelve, and bring the ſun's place to the eaſtern ſide of the horizon: then the number of degrees, intercepted between that degree of the equator now come to the horizon and the beginning of Aries, is the ſun's oblique aſcenſion. 2. The degrees on the horizon, intercepted between the eaſt point thereof and the point wherein the ſun is, is the ortive or riſing amplitude. 3. The hour, pointed to by the index, is the time of the ſun's riſing. 4. Turning the globe till the index points to the preſent hour, lay the quadrant to the ſun's place: the degree cut by the quadrant, in the horizon, is the ſun's azimuth.

To find the ſun's oblique deſcenſion, weſtern amplitude, and azimuth, with the time of ſetting.—The ſolution of this problem is the ſame as that of the former; excepting that the ſun's place muſt be here brought to the weſtern ſide of the horizon, as in the former it was to the eaſtern.

To find the length of day and night.—1. Find the time of the ſun's riſing, which being numbered from midnight, the double thereof gives the length of the night. 2. Subtract the length of the night from the whole day, or twenty-four hours, and the remainder is the length of the day.

To find the riſing, ſetting and culminating of a ſtar; its continuance above the horizon for any place and day; together with its oblique aſcenſion and deſcenſion, and its eaſtern and weſtern amplitude and azimuth.—1. Adjuſt the globe to the ſtate of the heavens at twelve o'clock that day. 2. Bring the ſtar to the eaſtern ſide of the horizon: thus will the weſtern amplitude and azimuth, and time of riſing, be found, as already taught of the ſun. 3. Bring the ſame ſtar to the weſtern ſide of the horizon: thus will the weſtern amplitude and azimuth, and the time of ſetting, be found. 4. The time of riſing, ſubtracted from that of ſetting, leaves the continuance of the ſtar above the horizon. 5. This continuance above the horizon, ſubtracted from twenty-four hours, leaves the time of its continuance below the horizon. 6. Laſtly, the hour to which the index points, when the ſtar is brought to the meridian, gives the time of its culmination.

To find the altitude of the ſun, or ſtar, for any given hour of the day or night.—1. Adjuſt the globe to the poſition of the heavens, and turn it till the index point at the given hour. 2. Fix on the quadrant of altitude, at 90 degrees from the horizon, and bring it to the ſun's or ſtar's place; the degrees of the quadrant, intercepted between the horizon and the ſun or ſtar, is the altitude required.

The altitude of the ſun by day, or of a ſtar by night, being given, to find the time of that day or night.—1. Rectify the globe as in the preceding problem. 2. Turn the globe and quadrant, till ſuch time as the ſtar, or degree of the ecliptic the ſun is in, cut the quadrant in the given degree of altitude; then does the index point at the hour ſought.

The azimuth of the ſun or a ſtar given, to find the time of the day or night.—Rectify the globe, and bring the quadrant to the given azimuth in the horizon; turn the globe, till the ſtar come to the ſame: then will the index ſhew the time.

To find the interval of time between the riſings of two ſtars, or the culminations.—1. Raiſe the pole of the globe ſo many degrees above the horizon, as is the elevation of the pole of the place. 2. Bring the firſt ſtar to the horizon, and obſerve the time the index points to. 3. The ſame do by the other ſtar: then ſubtracting the former time from the latter, the remainder is the interval between the riſings.

After the like manner is the interval between two culminations found, by bringing both ſtars to the meridian.

The day of the month being given, to find when any ſtar will come to the meridian.—Rectify for the ſun's place; turn the globe till the given ſtar comes to the meridian; then the index will point to the time ſought.

To find when any given ſtar will come to the meridian, at any given hour of the night.—Bring the given ſtar to the meridian; ſet the index to twelve at noon; then turn the globe eaſtward, till the index points to an hour as far diſtant in the forenoon from twelve as the given hour is in the afternoon, obſerve the degree of the ecliptic then at the meridian, over-againſt which degree, in the calendar, is the day of the month, when the given ſtar will be upon the meridian at the given hour.

By obſervation of a ſtar upon the meridian, to find the hour of the night.—Rectify for the latitude and the ſun's place; bring the given ſtar to the meridian, and the index will ſhew the hour of the night.

To find the beginning and ending of the crepuſculum or twilight.—1. Rectify the globe, and ſet the index to the twelfth hour, the ſun's place being in the meridian. 2. Note the ſun's place, and turn the globe weſtward, as alſo the quadrant of altitude, till the point oppoſite the ſun's place cut the quadrant of altitude in the eighteenth degree above the horizon: the index will then ſhew the time when the twilight commences in the morning. 3. Taking the point oppoſite to the ſun, bring it to the eaſtern hemiſphere, and turn it, till it meet with the quadrant of altitude in the eighteenth degree: then will the index ſhew the time when the twilight ends.

Given the ſun's longitude and the obliquity of the ecliptic, to find the ſun's right aſcenſion and declination.—Find the ſun's longitude or place on the ecliptic, and bring it to the brazen meridian. Then the arc of the equator, between the firſt point of Aries and the brazen meridian, ſhews the ſun's right aſcenſion; and the arc of the brazen meridian between the equator and the ecliptic ſhews the declination.

Given the obliquity of the ecliptic and the ſun's declination, to find the ſun's longitude and right aſcenſion.—Mark the ſun's declination on the brazen meridian, and turn the globe till the ecliptic comes under the figure; then will the diſtance from the meridian to the firſt point of Aries ſhew the ſun's longitude on the ecliptic, and its right aſcenſion on the equator.

Given the obliquity of the ecliptic and the ſun's right aſcenſion, required the ſun's declination and longitude.—Bring the ſun's right aſcenſion in the equator to the brazen meridian, then will the intercepted arc of the ecliptic to Aries ſhew the ſun's longitude; and the arc of the meridian, that is between the ſun's right aſcenſion and longitude, will ſhew the declination.

To find on what day the ſun begins to ſhine conſtantly at any given place in either of the frigid zones, and how long he continues to ſhine without intermiſſion at the ſame place.—Subtract the latitude of the given place from 90°, and find in what two days of the year the ſun's declination is exactly equal to the remainder, and of the ſame kind as the latitude of the place; then on the firſt of thoſe days in the ſpring quarter, the ſun ceaſes to ſet at the given place, and ſhines without intermiſſion there till he arrives at another point of the ecliptic, as many degrees on the other ſide of the ſummer ſolſtice, when his declination is again equal to the complement of the latitude: the ſpace of time between thoſe two days is the length or duration of the longeſt day.

To find the latitude of thoſe places in the north frigid zone, where the ſun begins to ſhine conſtantly on any day between the vernal equinox and the ſummer ſolſtice, or in the ſouth frigid zone on any day between the autumnal equinox and the winter ſolſtice.—Find the ſun's declination for the given day; ſubtract it from 90°, and the remainder will be the latitude of thoſe places: where the ſun begins to ſhine conſtantly the latitude is of the ſame kind as the ſun's declination.

To determine under what latitude two given ſtars riſe or ſet at the ſame inſtant.—Bring one of the ſtars to the horizon, and, keeping it there, raiſe or depreſs the pole till the other is on the horizon at the ſame time, obſerving whether this is effected on the eaſt or weſt poſition of the horizon; then the degree of the meridian, interſected by the horizon, will be the latitude of the place required.

To find at what place a given ſtar is vertical at any given hour at London; e. g. at what place will Capella be vertical the 2d of March at 10 *o'clock afternoon, at London time.*

N. B.—This problem requires the aſſiſtance of both the terreſtrial and celeſtial globes.

1. Find, as above, the time of the meridian paſſage of the

ſtar: in the preſent inſtance Capella paſſes about 6 o'clock in the afternoon.

2. Find under what meridian they reckon 6 o'clock when it is 10 with us, which will be four hours to the weſt.

3. Obſerve under this meridian the place whoſe latitude is equal to the declination of the ſtar, which, in this example, is nearly 46°: and this place, which is near Louiſburg, in North America, will be the place required.

To explain the phenomena of the harveſt-moon by the globe, ſee Moon.

Globe, *Terreſtrial,* is an artificial ſphere, on whoſe ſurface are delineated the principal places of the earth, in their proper ſituations, diſtances, &c. together with their circles imagined on the ſurface of the terreſtrial ſphere. The uſe of the terreſtrial globe, is to exhibit the ſeveral affections and phenomena of the different places of the earth, depending on magnitude, &c. in an eaſy obvious manner, without the trouble of trigonometrical calculations.

Globe, *To conſtruct a terreſtrial.*—The conſtruction of a terreſtrial globe, whether of metal, plaſter, paper, &c. is the ſame as that of a celeſtial. The ſame circles are delineated on both: and as for the places, *viz.* cities, towns, &c. they are laid down from the longitudes and latitudes given, as the ſtars are from their right aſcenſions and declinations.

Hence all problems, depending on the circles, may be equally wrought on either globe; as the aſcenſions, deſcenſions, amplitudes, azimuths, riſings, ſettings, altitudes, &c. of the ſun; the lengths of day and night; hours of the day and night; crepuſcula, &c.

We ſhall here, therefore, only give what is peculiar to the terreſtrial globe.

Globe, *Uſe of the terreſtrial. To find the longitude and latitude of any place delineated on the globe.*—Bring the place to the graduated ſide of the braſs meridian: the degree of the meridian it cuts is the latitude required; and the degree of the equator, at the ſame time under the meridian, is the longitude required.

The longitude and latitude given, to find the place on the globe.—Seek, in the equator, the given degree of longitude, and bring it to the meridian: then count from the equator on the meridian the degrees of latitude given, towards this or that pole, as the latitude is either north or ſouth: the point under this is the place required.

The hour being given at any place, to find what hour it is in any other part of the world.—Bring the given place to the meridian, and ſet the hour-index to the given hour; then, by turning the globe, bring any place to the meridian, and the index will point to the hour of that place.

To find the antœci, periœci, and antipodes of any place.—1. The given place being brought to the meridian, count as many degrees on the meridian from the equator towards the other pole: the point which is thus arrived at is the place of the antœci. 2. Note the degree of the meridian over the given place and its antœci, and turn the globe till the oppoſite degree of the equator come under the meridian; or, which amounts to the ſame, till the index, which before ſtood at twelve, come to the other twelve: then will the place, correſponding to the former degree, be the periœci; and the latter, that of the antipodes.

To find what place of the earth the ſun is vertical to at any time aſſigned.—1. Bring the ſun's place found in the ecliptic to the meridian, and the index to the hour of twelve, noting what point of the meridian correſponds thereto. 2. If the given hour be before noon, ſubtract it from twelve hours, and turn the globe towards the weſt, till the index points at the hours remaining: thus will the place required be under the point of the meridian before noted. 3. If the hour be after noon, turn the globe in the ſame manner towards the weſt, till the index points at the given hour: thus, again, will the place required be found under the point of the meridian before noted.

If, at the ſame time, you note all the places which are under the ſame half of the meridian with the place found, you will have all the places to which the ſun is then in the meridian; and the oppoſite half of the meridian will ſhew all the places in which it is then mid-night.

A place being given in the torrid zone, to find the two days in the year wherein the ſun is vertical in the ſame.—1. Bring the given place to the meridian, and note the degree of the meridian correſponding thereto. 2. Turn the globe about, and note the two points of the ecliptic paſſing through that degree. 3. Find on what days the ſun is in theſe points of the ecliptic: for on thoſe days he is vertical to the given place.

To find thoſe places in the torrid zone to which the ſun is vertical on a given day.—Bring the ſun's place in the ecliptic to the meridian; then turning the globe round, note all the places which paſs through that point of the meridian: thoſe are the places required.

After the ſame manner may be found what people are aſcii for any given day.

The day and hour at any place being given, to find where the ſun is vertical at that hour.—Bring the ſun's place to the meridian, and the degree over it is the ſun's declination at that time; then bring the given place to the meridian, and ſet the index to the given hour; turn the globe till the index points to twelve at noon, and the place on the globe which lies under the degree of the ſun's declination has the ſun then vertical.

A place being given in the frigid zone, to find the time when the ſun begins to appear above the horizon, and when it begins to diſappear; and alſo the length of the longeſt day or night in that place.—Rectiſy for the latitude; bring the aſcending part of the ecliptic, *i. e.* for latitudes north of the tropic of Cancer the ſemicircle intercepted between Capricorn and Cancer, to the ſouth point of the horizon; obſerve the degree of the ecliptic which cuts that point, and find when the ſun enters that degree, and this will give the time when the ſun begins to appear in that latitude. Bring the deſcending part of the ecliptic to the ſame point of the horizon, and the calendar will ſhew when the ſun leaves that latitude and diſappears. Again, bring the aſcending part of the ecliptic to the north point of the horizon, and the degree, as before, will ſhew in the calendar when the longeſt day begins; and by bringing the deſcending part of the ecliptic to the ſame north point, we ſhall find, in the ſame manner, when the longeſt day ends.

To find the latitude of the places wherein any given day is of any given length.—1. Bring the ſun's place for the given day to the ecliptic, and ſet the index to the hour of twelve. 2. Turn the globe, till the index points at the hour of riſing or ſetting. 3. Raiſe and depreſs the pole till the ſun's place appear in the eaſtern and weſtern ſide of the horizon: then will the pole be duly elevated, and, conſequently, the latitude given.

To find the latitude of thoſe places in the frigid zone where the ſun does not ſet for a given number of days.—1. Count ſo many degrees from the next tropic, towards the equinoctial point, as there are units in half the number of the given days; becauſe the ſun, in its proper motion, goes nearly a degree every day. 2. Bring the point of the ecliptic, thus found, to the meridian; and its diſtance from the pole will be equal to the elevation of the pole, or latitude of the places required.

Any hour of the day or night being given, to ſhew all thoſe places to which the ſun riſes and ſets; where it is noon or midnight; and where day or night.—1. Find what place the ſun is at that time vertical to, as already taught. 2. Let this place be brought to the zenith of the wooden horizon, *i. e.* elevate the pole as the latitude of that place requires; then will the places on the eaſtern ſide of the horizon be thoſe the ſun is ſetting to; and on the weſtern ſide, thoſe he riſes to: thoſe under the upper ſemi-circle of the meridian have it noon; and thoſe under the lower, midnight. Laſtly, to thoſe of the upper hemiſphere it is day; and to thoſe in the lower, night.

Hence, as in the middle of an eclipſe, the moon is in that degree of the ecliptic oppoſite to the ſun's place; by the preſent problem it may be ſhewn what places of the earth then ſee the middle of the eclipſe, and what the beginning or ending.

To find what places of the earth a planet, e. gr. *the moon, is vertical to any day of the year.*—1. Mark the planet's place on the globe, as above taught. 2. Bring this place to the meridian, and note the degree over it. 3. Turn the globe round, and the places which paſs under the point are thoſe required.

The declination of a ſtar, or any other phenomenon, given, to find what parts of the earth the ſame is vertical to.—Count as many degrees in the meridian, from the equator towards one pole, as are equal to the given declination; *viz.* towards the north, if the declination be to the northward; and towards the ſouth, if the declination be ſouth. Then turning it round, the places that paſs through the extremity of this arch in the meridian are the places required.

To determine the place of the earth where any ſtar, or other celeſtial phenomenon, will be vertical at a given hour.—1. Elevate the pole according to the latitude of the place, from whoſe noon or midnight the hours are numbered. 2. Bring the ſun's place for that day to the meridian, and ſet the index at twelve o'clock. 3. Determine the place of the ſtar on the ſurface of the globe, and bring it to the meridian; the index will ſhew the difference of time between the impulſe of the ſun and ſtar to the meridian of the place: note the point of the meridian over the place of the ſtar. 4. Find in what places of the earth it is then noon, and ſet the index to twelve o'clock. 5. Turn the globe towards the weſt, till the index has paſſed over the interval of time between the culmination of the ſun and ſtar. Then, under the point of the meridian, before obſerved, will the place required be found. And hence may always be found what place a ſtar, or other phenomenon, riſes or ſets to at any given time.

To place the globe in ſuch manner, under any given latitude, as that the ſun ſhall illuminate all thoſe regions which he actually illumines on earth.—1. Rectify the globe, *i. e.* elevate the pole according to the latitude of the place; bring the place to the meridian, and ſet the globe north and ſouth by the compaſſes; thus, the globe having the ſame ſituation with regard to the ſun as the earth has, that part thereof will be illuminated which is illuminated on earth. Hence alſo the globe being ſituate in the ſame manner, when the moon ſhines, it will ſhew what parts are then illuminated by the moon.

And in the like manner, we may find when the ſun and moon riſe and ſet at any given time.

To find the diſtance of two places on the globe.—Take the given places in the compaſſes, and apply them to the equator: the degrees which there ſubtend being reduced into miles, leagues, or the like, give the diſtances required.

The ſame may be done, and that more commodiouſly, by laying the graduated edge of the quadrant of altitude over the two places, and noting the degree intercepted.

To find how any one place bears from another.—Bring one place to the meridian, and lay the quadrant of altitude over the other, and it will ſhew on the horizon the point of the compaſs on which the latter bears from the former.

Problems on the terreſtrial globe may ſometimes be advantageouſly ſolved, by conſidering the horizon as the circle of illumination, and bringing the ſun's place to the zenith.

To find for any given day and hour thoſe places where the ſun is then riſing or ſetting, thoſe places where it is noon, and in particular that place where the ſun is vertical; thoſe places that have morning or evening twilight; and thoſe places where it was midnight.—Find the ſun's place in the ecliptic for the given day, bring it to the brazen meridian, and mark its declination.

Elevate the (north or ſouth) pole as many degrees above the horizon as are equal to the ſun's declination (north or ſouth). Bring the given place to the meridian, and ſet the index to the given hour, then turn the globe on its axis, till the index comes to the upper twelve, and fix the globe in that poſition. All theſe places along the weſtern edge of the horizon have the ſun riſing, thoſe along the eaſtern edge have the ſun ſetting: it is noon to the places under the brazen meridian, and amongſt them the ſun is vertical to that place, which ſtands under the degree of the ſun's declination.

Thoſe places that are within 18° of the weſtern ſemi-circle of the horizon have morning twilight, and thoſe within 18° of the eaſtern ſemi-circle have evening twilight: and it is midnight at all thoſe places under that part of the brazen meridian which is below the horizon. In ſhort, it is day to all places above the horizon, and either twilight or dark night to all thoſe which are below it.

The day and hour of a lunar eclipſe being given, to find thoſe places where it will be viſible.—Find the place where the ſun will be vertical when the eclipſe begins, and rectify the globe, in reſpect to latitude, for the antipodes of that place. Then bring the antipodes to the upper part of the brazen meridian, and fix the globe in that poſition, and the beginning of the eclipſe will be viſible to all places which are then above the horizon.

To find the proportion which the land bears to the ſea.—For this purpoſe Dr. Long propoſes to take the papers of a large terreſtrial globe, and after ſeparating the land from the ſea with a pair of ſciſſars, to weigh them carefully in ſcales. This method ſuppoſes the globe to be exactly delineated, and all the papers of equal thickneſs. By an experiment on the papers of Mr. Senex's ſeventeen inch globe, he found that thoſe comprehending the ſea weighed 349 grains, and the others only 124; whence he infers, that almoſt three-fourth parts of the ſurface of our earth between the polar circles are covered with water, and that little more than one-fourth is dry land. Dr. Long omitted weighing the papers within the polar circles, becauſe the proportion which the land bears to the ſea within them is not aſcertained. Long's Aſtron. vol. i. p. 168. See *Magnitude of the* EARTH.

GLOBE, *To conſtruct a dial by the.* See DIAL.

The celeſtial globe has been improved by Mr. Ferguſon: in this globe, (*Plate* XV. *Aſtronomy, fig.* 122.) an arch MKH, of 23½°, is fixed on the north pole of the axis, above the hour circle; and at the end is fixed an upright pin HG, ſtanding directly over the north pole of the ecliptic, and perpendicular to that part of the ſurface of the globe. On this pin are two moveable collets at D and H, to which are annexed the quadrantal wires N and O, carrying two little balls repreſenting the ſun and moon. The collet D is fixed to the circular plate F, on which are engraven the $29\frac{1}{2}$ days of the moon's age, beginning under the wire N, which wire, as it turns round, carries with it the plate F. Theſe wires are fixed or ſlackened by the ſcrew G, and the two little balls are made to riſe and ſet at the ſame time and on the ſame point of the horizon, for the day to which they are rectified, as the ſun and moon do in the heavens. The ball repreſenting the moon may be ſcrewed as many degrees to either ſide of the ecliptic, as her latitude amounts to at any given time; and for this purpoſe, S is a ſmall piece of paſteboard, the curved edge of which at S is to be ſet upon the globe at right angles to the ecliptic, and the dark line over S to ſtand upright upon it: from this line, on the convex edge, are drawn the $5\frac{1}{3}$ degrees of the moon's latitude on both ſides of the ecliptic; and when this piece is ſet upright on the globe, its graduated edge reaches to the moon on the wire O, by which means ſhe is eaſily adjuſted to her latitude found by an ephemeris. The horizon of this globe is ſupported by two ſemi-circular arches, becauſe pillars would ſtop the progreſs of the balls, when they go below the horizon in an oblique ſphere. This globe is rectified by elevating the pole to the latitude of the place, bringing the ſun's place in the ecliptic for the given day to the brazen meridian, and ſetting the hour-index to twelve at noon; then, ſetting the ſun directly over his place in the meridian, and the moon over her place in the ecliptic, by fixing her wire under the number that expreſſes her age for that day on the plate F; and, laſtly, laying the curved edge of the paſteboard S over the ecliptic below the moon, and adjuſting the moon to her latitude over the graduated edge of the paſteboard. Having thus rectified the globe, turn it round, and obſerve on what point of the horizon the ſun and moon balls riſe and ſet; for theſe agree with the points of the compaſs on which the ſun and moon riſe and ſet in the heavens on the given day: and the hour-index ſhews the times of their riſing and ſetting, and alſo the time of the moon's paſſing over the meridian. This globe is alſo contrived for exhibiting the phenomena of the harveſt-moon, &c. Phil. Tranſ. Nº 483. art. 21. in vol. xliv. p. 535, or Ferguſon's Aſtron. p. 291.

Globe, *Dialling*. See Dialling.

Globes, *Patent*, are thoſe with the improvements of Mr. Neale, for which he obtained his majeſty's letters patent; by means of which he ſolves ſeveral aſtronomical problems, which do not admit of ſolution by the common globes.

Globe, *Planetary*, is a machine contrived and deſcribed by Mr. Ferguſon; in which T (*Plate* XV. *Aſtronomy*, *fig.* 123) is a terreſtrial globe fixed on its axis ſtanding upright on the pedeſtal C D E, on which is an hour circle, having its index fixed on the axis, which turns ſomewhat tightly in the pedeſtal, ſo that the globe may not be liable to ſhake: to prevent which, the pedeſtal is about two inches thick and the axis goes quite through it, bearing on a ſhoulder. The globe is hung in a graduated brazen meridian, much in the uſual way; and the thin plate N, N E, E, is a moveable horizon graduated round the outer edge, for ſhewing the bearings and amplitudes of the ſun, moon, and planets. The brazen meridian is grooved round the outer edge; and in this groove is a ſlender ſemi-circle of braſs, the ends of which are fixed to the horizon in its north and ſouth points: this ſemi-circle ſlides in the groove as the horizon is moved in rectifying it for different latitudes. To the middle of the ſemi-circle is fixed a pin, which always keeps in the zenith of the horizon, and on this pin the quadrant of altitude q turns; the lower end of which, in all poſitions, touches the horizon as it is moved round the ſame. This quadrant is divided into 90 degrees from the horizon to the zenithal pin on which it is turned, at 90. The great flat circle or plate A B is the ecliptic, on the outer edge of which the ſigns and degrees are laid down; and every fifth degree is drawn through the reſt of the ſurface of this plate towards its centre. On this plate are ſeven grooves, to which ſeven little balls are adjuſted by ſliding wires, ſo that they are eaſily moved in the grooves, without danger of ſtarting out of them. The ball next the terreſtrial globe is the Moon, the next without it is Mercury, the next Venus, the next the Sun, then Mars, then Jupiter, and laſtly Saturn; and in order to know them, they are ſeparately ſtampt with the following characters: ☽, ☿, ♀, ☉, ♂, ♃, ♄. This plate or ecliptic is ſupported by four ſtrong wires, having the lower ends fixed into the pedeſtal at C, D, and E, the fourth being hid by the globe. The ecliptic is inclined $23\frac{1}{2}$ degrees to the pedeſtal, and is therefore properly inclined to the axis of the globe which ſtands upright on the pedeſtal.

To rectify this machine.—Set the Sun, and all the planetary balls, to their geocentric places in the ecliptic for any given time, by an ephemeris; then ſet the north point of the horizon to the latitude of your place on the brazen meridian, and the quadrant of altitude to the ſouth point of the horizon; which done, turn the globe with its furniture till the quadrant of altitude comes right againſt the Sun, *viz.* to his place in the ecliptic; and keeping it there, ſet the hour index to the XII. next the letter C.

By this machine the following problems, as well as many others, may be reſolved.

To find the amplitude, meridian altitudes, and times of riſing, culminating, and ſetting of the ſun, moon, and planets.—Turn the globe round eaſtward, or according to the order of the ſigns; and as the eaſtern edge of the horizon comes right againſt the ſun, moon, or any planet, the hour-index will ſhew the time of its riſing; and the inner edge of the ecliptic will cut its riſing amplitude in the horizon. Turn on, and as the quadrant of altitude comes right againſt the ſun, moon, or planets, the ecliptic cuts the meridian altitudes in the quadrant, and the hour-index ſhews the times of their coming to the meridian. Continue turning, and as the weſtern edge of the horizon comes right againſt the ſun, moon, or planets, their ſetting amplitudes are cut in the horizon by the ecliptic; and the times of their ſetting are ſhewn by the index on the hour-circle.

To find the altitude and azimuth of the ſun, moon, and planets, at any time of their being above the horizon.—Turn the globe till the index comes to the given time in the hour-circle; and keep the globe ſteady, and moving the quadrant of altitude to each planet reſpectively, the edge of the ecliptic will cut the planet's mean altitude on the quadrant, and the quadrant will cut the planet's azimuth, or point of bearing on the horizon.

The ſun's altitude being given at any time either before or after noon, to find the hour of the day, and the variation of the compaſs, in any known latitude.—With one hand hold the edge of the quadrant right againſt the ſun; and, with the other hand, turn the globe weſtward, if it be in the forenoon, or eaſtward if it be in the afternoon, until the ſun's place at the inner edge of the ecliptic cuts the quadrant in the ſun's obſerved altitude; and then the hour-index will point out the

the time of the day, and the quadrant will cut the true azimuth, or bearing of the ſun for that time: the difference between which, and the bearing ſhewn by the azimuth compaſs, ſhews the variation of the compaſs in that place of the earth. Ferguſon's Aſtron. p. 292, &c.

Globe *Amaranth.* See Gomphræna.

Globe *Animalcule*, in *Natural Hiſtory*, is a ſingular, minute, aquatic animal, whoſe form ſeems exactly globular, without either head, tail, or fins. It moves in all directions, either rolling like a bowl, or gliding along ſmoothly without turning itſelf at all. Its whole body is tranſparent, except where it is covered with circular black ſpots; ſome of which have ſix or ſeven, ſome one, two, three, four or five, and others none at all. Theſe ſpots are probably the eggs or young ones of the animal. The general appearance of the body exhibited a kind of ſhort moveable hairs or briſtles, by means of which it is conjectured the motions of the animal may be performed. Baker's Microſ. 1753, p. 322, &c.

Globe, *Daiſy.* See Globularia.

Globe *Fiſh*, in *Ichthyology*, a name by which ſome ſpecies of the oſtracion are called. See Ostracion.

Globe *Flower*, in *Botany*. See Sphæranthus.

Globe *Ranunculus*. See Trollius.

Globe *Thiſtle.* See Echinops.

GLOBULAR Chart, a repreſentation of the ſurface, or ſome part of the ſurface, of the terraqueous globe upon a plane; wherein the parallels of latitude are circles nearly concentric: the meridians, curves, bending towards the poles; and the rhumb-lines alſo curves.

The merits of this chart conſiſt in this, that the diſtances between places on the ſame rhumb are all meaſured by the ſame ſcale of equal parts; and the diſtance of any two places in the arch of a great circle, is nearly repreſented in this chart by a ſtraight line. Hence land-maps, made according to this projection, would indiſputably have great advantages above thoſe made any other way. See Map.

But for ſea charts, and the uſe of navigation, it is yet controverted, whether the globular chart be preferable to Mercator's, where the meridians, parallels, and particularly the rhumb-lines, are all ſtraight lines; inaſmuch as ſtraight lines are found more eaſy to draw and manage than curves, eſpecially ſuch as rhumb-lines on the globular chart are. This projection is not new, though not much taken notice of till of late. It is mentioned by Ptolemy in his Geography; as alſo by Blundeville, in his Exerciſes. See Chart.

Globular *Projection.* See Projection.

Globular *Sailing.* See *Great-circle* Sailing.

GLOBULARIA, in *Botany*, was ſo called by Tournefort, becauſe its flowers grow in the ſhape of a little globe or ball.—Linn. Gen. 47. Schreb. 63. Willd. Sp. Pl. v. 1. 539. Ait. Hort. Kew. ed. 2. v. 1. 222. Mart. Mill. Dict. v. 2. Lamarck Dict. v. 2. 730. Illuſtr. t. 56. Tourn. t. 265. Gærtn. t. 44. Juſſ. 97.—Claſs and order, *Tetrandria Monogynia.* Nat. Ord. *Aggregatæ*, Linn. *Lyſimachiæ*, Juſſ.

Gen. Ch. *Cal.* Common perianth imbricated, with equal ſcales, the length of the diſk; proper perianth of one leaf, tubular, five-cleft, acute, permanent. *Cor.* General one nearly equal; proper one of a ſingle petal, tubular at the baſe; limb in five ſegments; the upper lip very narrow, cloven, ſhorteſt; the lower conſiſting of three larger, equal ſegments. *Stam.* Filaments four, ſimple, as long as the proper corolla; anthers diſtinct, incumbent. *Piſt.* Germen ſuperior, ovate; ſtyle ſimple, the length of the ſtamens; ſtigma obtuſe. *Peric.* none; proper calyx ſhutting up and encloſing the ſolitary, ovate *ſeeds.* Common *receptacle* oblong, divided by ſcales.

Eſſ. Ch. Common calyx imbricated; proper one tubular, inferior. Partial corollas with the upper lip cloven; under one three-cleft. Receptacle chaffy.

1. G. *longifolia.* Long-leaved Globularia. Willd. Sp. Pl. v. 1. 539; (Alypum ſive Herba terribilis; Sloan. Jam. v. 1. 19. t. 5. f. 3.)—"Stem ſhrubby. Leaves linear-lanceolate, entire. Heads of flowers axillary."—This green-houſe ſhrub is a native of Madeira, flowering in July and Auguſt. The *wood* of this plant is hard and white, with a very large *pith*, and an unequal light brown or grey *bark*. *Leaves* growing very thick towards the ends of the *branches*. *Flowers* conſiſting of ſeveral ſpherical heads, of a blueiſh colour. *Seed* pappous, all over downy.

2. G. *Alypum.* Herb Terrible. Linn. Sp. Pl. 139. (Alypum montis Ceti; Ger. em. 506.)—"Stem ſhrubby. Leaves obovato-lanceolate, three-toothed or undivided. Heads of flowers terminal."—A green-houſe ſhrub, found in various parts of the ſouth of Europe, flowering from Auguſt to November. *Root* woody. *Leaves* alternate, faſciculated in the lower *axillæ*, near an inch long, glaucous, ſome are undivided, others three-toothed. *Flowers* blue or purple. The whole plant is bitter, and purgative in a violent degree.

3. G. *biſnagarica.* Linn. Sp. Pl. 139. (Scabioſa biſnagarica ſive G. fruteſcens; Pluk. Amalth. t. 58. f. 5.)—"Stem ſhrubby. Radical-leaves wedge-ſhaped, abrupt; ſtem-leaves lanceolate."—Native of the woods of India. *Stem* of many ſtraight, hard, leafy branches, each about five or ſix inches high. *Flowers* in a blue terminal head.

4. G. *vulgaris.* Blue Daiſy. Linn. Sp. Pl. 139. (Aphyllanthes anguillaræ; Camer. Hort. t. 7.)—"Stem herbaceous. Radical-leaves three-toothed. Stem-leaves lanceolate."—A hardy perennial, common in ſome parts of Europe, and flowering in May and June. *Root* woody. *Stem* a ſpan high, terminated by a head of deep blue *flowers*. Willdenow mentions two varieties of this ſpecies, one with a *leafleſs ſtem*, the other with *white flowers*.

5. G. *ſpinoſa.* Linn. Sp. Pl. 139.—"Radical-leaves crenate-prickly; ſtem-leaves entire, pointed."—Native of Spain, Albinus having gathered it in Granada. It flowers in May. —*Radical-leaves* numerous, ſmall, ſtiff and notched, each notch ending in a prickle. *Flowers* compoſing an oblong ſphere, hairy.—We are not acquainted with any figure of this ſpecies.

6. G. *cordifolia.* Linn. Sp. Pl. 139. Jacq. Auſtr. t. 245.—"Stem nearly naked. Leaves wedge-ſhaped, with three points; the middle one very ſmall."—Native both of hills and vales in Hungary, Auſtria, and Switzerland, flowering from April to July. *Root* creeping, each joint throwing out a cluſter of *leaves*, from the centre of which ſprings a ſmooth purpliſh *ſtem* about four inches long, terminated by a head of blue *flowers*.

7. G. *nana.* Willd. Sp. Pl. v. 1. 542.—"Flower-ſtalks naked, very ſhort, leaves ſpatulate, ſomewhat ovate, entire."—Found in the ſouth of France, and on the Pyrenées, where our dried ſpecimen was gathered by Dr. Noehden. —*Root* woody and very thick, bearing numerous tufts of little *leaves*, among which ariſe the ſhort, ſolitary flower-ſtalks. *Flowers* forming a terminal head.—It has never been figured.

8. G. *nudicaulis.* Linn. Sp. Pl. 140. Jacq. Auſtr. t. 230.—"Stem naked, leaves entire lanceolate."—Native of mountainous and ſtony places in Auſtria and Switzerland, flowering in July.—*Root* perennial, fibrous, creeping, throwing out numerous, thickiſh, firm *leaves*, darker on the up-

per ſide. *Flower-ſtalk* about ſix inches long, ſmooth, ſtriated, purpliſh towards the top, bearing a roundiſh head of blue *flowers*.

9. G. *orientalis*. Linn. Sp. Pl. 140.—" Stem nearly naked. Heads of flowers alternate, ſeſſile, leaves ovate, ſomewhat lanceolate, entire."—This ſpecies is a native of Natolia. —*Root* perennial. *Leaves* numerous, obovate, running down into the foot-ſtalks, acute, undivided, naked. *Stem* a foot high, herbaceous, perfectly ſimple. *Leaves* alternate, ſmall, lanceolate, remote. *Heads of flowers* alternate, ſeſſile, from ſeven to ten, at the ſummit of the ſtem.—Linnæus deſcribed G. *orientalis*, having received it from M. Biorling, but it is nowhere figured.

Globularia, in *Gardening*, contains plants of the herbaceous, flowery, perennial kind; of which the ſpecies chiefly cultivated are the three-tooth-leaved globularia (G. alypum); and the common globularia or blue daiſy (G. vulgaris); but others may be eaſily raiſed.

There are two varieties of the laſt ſort, one with a white flower, and another that has a leafleſs ſtem.

Method of Culture.—In the firſt it may be effected by planting cuttings of the young branches in April, juſt before they begin to ſhoot, in pots of light freſh mould, plunging them in a very moderate hot-bed, and giving them due water and ſhade, till they have ſtricken root. After this they ſhould be removed from the bed, and be gradually hardened to the open air, being protected during the winter months.

The ſecond ſort may be readily increaſed by parting the roots, as in the common daiſy, planting them out in the early part of the autumn, in moiſt ſhady ſituations. They ſucceed beſt in ſuch loamy ſoils as are rather moiſt in their quality.

The firſt affords variety among potted plants, and the latter in the fronts of the more moiſt and ſhady borders and clumps of pleaſure-grounds.

GLOBULE, Globulus, a little *globe*; otherwiſe called a *ſpherule*.

Thus the red particles of the blood are called globules of the blood, on account of their redneſs and ſmallneſs. (See Blood.) The Carteſians call the particles broken off the matter of the firſt *element*, *globules of the ſecond element*. See Carteſian, &c.

GLOBULUS Nasi, is uſed for the lower, flexible, cartilaginous part of the noſe.

GLOCHIDION, in *Botany*. See Bradleja.

GLOESZTI, in *Geography*, a town of Walachia; 50 miles N. of Buchareſt. N. lat. 49° 13'. E. long. 26° 16'.

GLOGAU, a principality of Sileſia, on the E. ſide of the Oder, bordering on Poland; producing corn and wine in abundance, in ſome parts affording mines of iron. The paſtures feed many ſheep, and the wool is wrought into different manufactures. It is divided into ſix circles. In the year 1241, it was governed by its own princes; but afterwards it belonged to the king of Poland, to the king of Bohemia, to the emperor, and laſt of all to the king of Pruſſia.

Glogau, *Gros* or *Great*, the capital of the principality of the ſame name, built in 1110 on the S. ſide of the Oder, taken by the Pruſſians in 1741, and ſtrengthened by new fortifications. It is the ſeat of a governor, a commandant, divers tribunals, and a biſhop's court, &c. It contains two Catholic churches, of which one is collegiate, three convents, a Lutheran church and ſchool, and a chapel for Calviniſts; 62 miles N.W. of Breſlau. N. lat. 51° 39'. E. long. 16° 5'.

Glogau, *Ober*, or *Little*, a town of Sileſia, in the principality of Oppeln; 19 miles S. of Oppeln. N. lat. 50° 16'. E. long. 17° 48'.

GLOGNITZ, a town of Auſtria; 28 miles S. of Vienna.

GLOKEN-SPEISSE, in *Mineralogy*, a term uſed by the Germans to expreſs a ſort of impure regulus of biſmuth, obtained by accident, ſometimes in the making of ſmalt. The biſmuth ores are often ſo intimately mixed with the cobalt, that they cannot be ſeparated from them. In this caſe, the arſenic being raiſed in the flowers, there remains at the bottom, inſtead of the fixed vitrifiable earth of the cobalt, a ſort of impure regulus of a reddiſh colour. This is biſmuth, with an admixture of the earth of cobalt, and other extraneous matter. They ſometimes call this whole matter by the common name of ſpeiſſe; but more uſually they ſeparate it into two parts, and call the under part, which is moſt ſolid, gloken-ſpeiſſe, and the upper part they diſtinguiſh by the name of æs caldarium.

GLOMERELLS, in our *Old Writers*, commiſſaries appointed to determine differences between ſcholars of a ſchool or univerſity, and the townſmen of a place. In the edict of the biſhop of Ely, anno 1276, there is mention of the maſter of the glomerells.

GLOMME, or Glomen, in *Geography*, called alſo the *Stor Elv*, or great river, the chief river of Norway, ſprings from the lake of Oreſund on the north of the Fœmund, and after running a courſe nearly ſouth about 300 Britiſh miles, diſcharges itſelf into the Northern Ocean near Frederickſtadt, to which town about 50,000 trees are annually floated upon it. This river, being full of cataracts and ſhoals, is not navigable. Before it receives the Worme, which iſſues from the lake Mioſs, it is about as broad as the Thames at Henley. In its courſe it preſents a broad ſurface, ſometimes watering pleaſant vallies, ſometimes intercepted by ſand-banks, over which it frequently ſhifts its courſe, ſometimes winding between rocky cliffs, and precipitating itſelf in frequent cataracts. Near Kongſwinger it is as broad as the Thames at Putney. Its rugged courſe, however, muſt render it a tremendous torrent.

GLON, a river of Bavaria, which runs into the Ammer, near Crantzberg.

GLONS, a town of France, in the department of the Ourte, and chief place of a canton, in the diſtrict of Liege. The place contains 1,500, and the canton 8,850, inhabitants, on a territory of 107½ kiliometres, in 23 communes.

GLOR-FAT, in *Rural Economy*, a term applied to animals that are extremely fat.

GLORIA Patri, in the *Liturgy*, a formula of words repeated at the end of each Pſalm, and on other occaſions, to give glory to the Trinity; called alſo the *Doxology*. It is thus denominated, becauſe it begins in the Latin office with theſe words; *Gloria Patri*, q. d. *Glory be to the Father*, &c.

Pope Damaſcus is commonly ſaid to have firſt ordered the rehearſal, or rather, ſinging the Gloria Patri at the end of Pſalms. Baronius, indeed, will have it to have been uſed in the times of the apoſtles: but its uſe, then, he allows to have been more obſcure, and that it did not become popular till after the riſe of Arianiſm, when it was made a kind of ſymbol of orthodoxy.

The fifth canon of the council of Vaiſon, held in 529, decrees, " that the name of the pope ſhall always be rehearſed in the churches of France, and after the Gloria Patri ſhall be added *ſicut erat in principio*, as is done at Rome, in Africa, &c. on account of the heretics, who ſay, that the Son of God had his beginning in time." Fleury.

Gloria *in excelſis* is alſo a kind of hymn rehearſed in divine ſervice, beginning with the words *Gloria in excelſis Deo, & in terra pax hominibus*, &c. *Glory be to God on high, on earth peace*, &c.

GLORIOSA, in *Botany*, ſo named on account of the ſplendour and magnificence of its flowers. Tournefort, objecting to the name given by Linnæus becauſe it is an adjective, called this genus *Methonica*, in which he has been followed by Juſſieu, and indeed by all French botaniſts, though the Linnæan ſchool have refuſed to adopt this barbarous name.—Linn. Gen. 164. Schreb. 220. Willd. Sp. Pl. v. 2. 95. Ait. Hort. Kew. v. 1. 434. Mart. Mill. Dict. v. 2. Gærtn. t. 18. Juſſ. 48.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Lilia*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* Petals ſix, oblong-lanceolate, waved, very long, entirely bent back, furniſhed at the baſe of their inſide with a honey-bearing furrow, between two ridges. *Stam.* Filaments ſix, awl-ſhaped, ſhorter than the corolla, horizontal; anthers incumbent. *Piſt.* Germen globoſe; ſtyle thread-ſhaped, longer than the ſtamens, horizontal; ſtigmas three, thread-ſhaped. *Peric.* Capſule ſuperior, oval, with three lobes, three cells, and three valves. *Seeds* numerous, globular, covered with pulp, and diſpoſed in two rows.

Eſſ. Ch. Corolla of ſix waved and reflexed petals. Style oblique.

1. G. *ſuperba*. Superb Lily. Linn. Sp. Pl. 437. Redout. Liliac. t. 26.—"Leaves furniſhed with tendrils."—Native of Malabar and Guinea. It was introduced into Kew Garden in 1690 by the firſt earl of Portland. A tender ſtove plant, flowering in July and Auguſt. The *ſtem* is herbaceous, about a fathom high, round, having two oppoſite lateral *branches*, and putting forth a flower-ſtalk from the boſom of each leaf. *Leaves* alternate, ſmooth, each ending in a *tendril*. *Flowers* pendent, of a moſt beautiful red and yellow colour. *Petals* lanceolate, long, waved at the edge, reflexed near the baſe. This remarkably handſome plant requires exceſſive heat to make it flower.

2. G. *ſimplex*. Linn. Mant. 62. Willd. Sp. Pl. v. 2. 96.—"Leaves pointed."—Native of Senegal. The *leaves* are not furniſhed with tendrils. *Flowers* blue.—There is no figure of this ſpecies known. It was merely taken up from Miller, nor has any thing been found which anſwers to the deſcription.

Obſ. This very beautiful genus is nearly allied to *Erythronium*.

Gloriosa, in *Gardening*, compriſes a plant of the herbaceous, flowering, perennial kind; of which the ſpecies cultivated is the ſuperb-lily (G. ſuperba.)

Method of Culture.—It is capable of being increaſed by planting the offſets from the old roots, either in the autumn after the ſtems decay, or in the early ſpring before they ſhoot, in pots filled with light earth, plunging them in the bark-bed of the ſtove. The old roots, when taken out of the ground, ſhould be preſerved in dry ſand during the winter in the ſtove, or in a dry warm room. It is the practice of ſome to let the roots remain during the winter in the mould, keeping the pots in the tan-bed; planting out the offſets early in the ſpring. In either way they ſhould have very little water given them.

When the ſtems appear they ſhould be ſupported by ſticks, and in hot dry weather a little water ſhould be ſparingly given, as there may be occaſion. And the pots in which they are planted ſhould be ſmall, that they may be confined, and put forth ſtronger ſtems. Two-penny pots will be large enough for the roots of the greateſt ſized plants of this nature.

The plants afford much effect by their beautiful flowers among thoſe of the ſtove kind, when properly intermixed with them.

GLORIOUS Islands, in *Geography*, two ſmall iſlands in the Indian ſea. S. lat. 11° 32′. E. long. 47° 15′.

GLOSKAR, a ſmall iſland in the Baltic, E. of Aland. N. lat. 60° 20′. E. long. 20° 13′.

GLOSS, Glossa, a comment on the text of any author, to explain his ſenſe more fully and at large, whether in the ſame language, or in any other. See Commentary.

The word, according to ſome, comes from γλωσσα, *tongue*; the office of a gloſs being to explain the text, as that of the tongue is to diſcover the mind. Others derive it from the Latin *gloſs*, of γαλως, *a ſiſter-in-law*, which among lawyers ſometimes ſtands for ſiſter; the gloſs being, as it were, ſiſter to the text.

Nic. de Lyra compoſed a poſtil or gloſs on the Bible, in ſix volumes folio. The French ſay, proverbially of an ill comment, that it is *gloſs d'Orleans, plus obſcure que le texte.*

Gloss is alſo uſed for a literal tranſlation, or an interpretation of an author in another language, word for word. Young ſcholars need an interlineary gloſs for the underſtanding of Juvenal, Horace, Salluſt, Perſius, &c.

Gloss is alſo uſed in matters of *Commerce*, &c. for the luſtre of ſilk, ſtuff, or the like.

GLOSSARY, Glossarium, a kind of dictionary for explaining the obſcure, ancient, and barbarous words and phraſes of an altered, corrupted, or refined language.

Spelman's gloſſary, entitled Archaiologicum, is an excellent work; though that author did not begin to ſtudy in this way till fifty years of age. M. Du Cange's Latin Gloſſary in ſix volumes, Paris, fol. 1733, Baſil, fol. 1762, is a work in high eſtimation, and containing a fund of the moſt curious and amuſing intelligence. Charpentier's ſupplement to this work, in 4 volumes, fol. Paris, 1766, is neceſſary to render this ſet of books complete. Du Cange's Greek Gloſſary in two volumes, fol. Lugd. 1688, is an excellent performance, full of uncommon erudition.

The Greek, Latin, and French gloſſaries of Du Cange form a ſeries of the moſt inſtructive articles in the ſtudy of juriſprudence and belles lettres. There is an abridgment of this work in 6 vols. 8vo.; which, however, contains ſome matter not common to either of the preceding. This abridgment is exceedingly rare. As a caution to the purchaſers of the Greek Gloſſary, we inform them that in the article "Moneta" (Coins, vol. iv. p. 904.) there ſhould be 10 plates of engravings of coins, and monograms of various princes and ſovereigns of Europe, which are ſometimes wanting, and thus the value of the edition is materially depretiated.

Lindenbroek has a Gloſſary on the laws of Charlemagne, &c.

GLOSSOCATOCHOS, in *Surgery*, an inſtrument for depreſſing the tongue. It is deſcribed by Paulus Ægineta, and the term is derived from γλωσσα, *the tongue*, and κατεχω, *to repreſs.*

GLOSSOCELE, denoting a ſwelling and protruſion of the tongue. The word comes from γλωσσα, *the tongue*, and κηλη, *a tumour.*

GLOSSOCOMA, a retraction of the tongue.

GLOSSOCOME, *in the Inſtrumental Muſic of the Greeks*, a name given by the ancients to a kind of caſe for the glottis, or tongues of their flutes, which probably were hautboys, and, conſequently, their glottis was a reed. See Glottis.

GLOSSOCOMON, in *Mechanics*, is a name given by Hi-ero, to a machine compoſed of divers dented wheels, with pinions ſerving to raiſe huge burdens.

Glossocomon, a term in *Surgery*, derived from γλωσσα, *the tongue*, and κομεω, *to guard*; originally a caſe for the reed of a hautboy, but uſed metaphorically to ſignify a caſe for a fractured limb.

GLOSSODIA, in *Botany*, (γλωσσοειδης, having the form or appearance of a tongue; in alluſion to the peculiar appendage to the internal part of the flower, which reſembles the tongue of a ſerpent, and affords the eſſential character. Brown Prod. Nov. Holl. v. 1. 325.—Claſs and order, *Gynandria Monogynia*. Nat. Ord. *Orchideæ*.

Gen. Ch. *Cal.* Perianth ſuperior, of three equal ſpreading leaves. *Cor.* Petals two, equal to and reſembling the calyx. Nectary of a different form, ſhorter, undivided, not glandular, accompanied, at its baſe above, by a cloven tongue-ſhaped appendage, between it and the ſtyle. *Stam.* Anther terminal, its cells cloſe together; maſſes of pollen two in each cell, compreſſed, powdery. *Piſt.* Germen inferior: ſtyle columnar, with a dilated membranous border at each ſide. *Peric.* Capſule. *Seeds* numerous.

Eſſ. Ch. Calyx and Corolla equal. Lip ſhorter, undivided, without glands, with an appendage at its baſe. Style dilated at each ſide. Anther vertical.

1. G. *major*. Brown 326.—“ Appendage cloven half way down; its lobes ſpreading, acute.”

2. G. *minor*. Ibid.—“ Appendage cloven to the baſe; its lobes parallel, obtuſe.”

Both ſpecies are natives of the country near Port Jackſon, New South Wales. Their *bulbs* are undivided, with a laminated coat, and grow in the earth, not paraſitically. *Herb* hairy. *Leaf* ſolitary, radical, its baſe encloſed in a membranous ſheath. *Stalk* radical, bearing generally one blue flower, rarely two, and furniſhed with one *bractea* beſides what accompanies each flower. *Brown.*

GLOSSOIDES, in *Natural Hiſtory*, a name given by ſome authors to a ſpecies of ſtone, reſembling the figure of the human tongue. This is a mere accidental configuration of a common flint or pebble, perfectly indeterminate in ſize and colour, and owing its form to no animal mould, as the ſtones found in ſhells uſually do, but is a mere luſus naturæ in the concretion of the ſtone.

GLOSSOMA, in *Botany*, ſo named by Schreber, from γλωσσα, *the tongue*, and ωμος, *the ſhoulder*, alluding to the tongue-ſhaped appendages borne by the anthers. Schreb. 792. Willd. Sp. Pl. v. 1. 664. Mart. Mill. Dict. v. 2. (Votomita; Aubl. Guian. v. 1. 90. Juſſ. 382.) Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Rhamnis affine*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, turbinate, four-toothed, permanent. *Cor.* Petals four, equal, lanceolate, acute, much longer than the calyx, recurved. Nectary a ring round the baſe of the ſtyle. *Stam.* Filaments four, very ſhort; anthers oblong, nearly united into a cylinder, elongated at the top into a membranous lanceolate expanſion of two cells, opening inwardly. *Piſt.* Germen inferior, obovate; ſtyle thread-ſhaped, as tall as the ſtamens; ſtigmas four, acute. *Peric.* Drupa pear-ſhaped, of one cell, crowned by the calyx. *Seed* ſolitary, ovate, ſtriated.

Eſſ. Ch. Calyx ſuperior, four-toothed. Petals four. Anthers cohering, each crowned with a lanceolate membrane. Stigmas four. Drupa with one furrowed nut.

Obſ. The above characters appear to be taken by Schreber from Aublet, nor have we any better materials. The only ſpecies known is,

1. G. *arboreſcens*; Willdenow. (Votomita guianenſis; Aubl. v. 1. 91. t. 35.)—A *ſhrub* of a middling ſize, whoſe trunk is five or ſix feet high, and five or ſix inches thick; the wood yellow, hard and compact. *Branches* knotty, ſpreading variouſly, leafy. *Leaves* oppoſite, elliptical, pointed, entire, ſix inches long, thick and firm, of a ſhining green, placed on ſhort ſtalks, with a deciduous ſtipula at each ſide of their baſe. *Flowers* white, on ſhort, umbellate, axillary ſtalks, their petals about half an inch long. This plant is found in the extenſive foreſts of Guiana, about the habitations of the natives. Nothing is recorded reſpecting its qualities or uſes.

GLOSSOPETALUM, ſo denominated by Schreber from the tongue-like appendages to the petals. Schreb. 205. Willd. Sp. Pl. v. 1. 1521. Mart. Mill. Dict. v. 2. (Goupia; Aubl. v. 1. 295. Juſſ. 378. Lamarck. Illuſtr. t. 217.)—Claſs and order, *Pentandria Pentagynia*. Nat. Ord. *Dumoſæ*, Linn. *Rhamni*, Juſſ.

Gen. Ch. *Cal.* Perianth half inferior, of one leaf, minute, five-toothed, permanent. *Cor.* Petals five, lanceolate, ſpreading, acute, much longer than the calyx, each bearing at its point a linear-lanceolate, abrupt appendage, almoſt of the length of the petal, bent back and lying upon it. *Stam.* Filaments five, very ſhort; anthers roundiſh. *Piſt.* Germen roundiſh, encircled by a glandular ring, which bears the petals and ſtamens; ſtyle none; ſtigmas five, acute. *Peric.* Berry roundiſh, with five furrows, of one cell. *Seeds* five, angular.

Eſſ. Ch. Calyx half inferior, with five teeth. Petals five, each bearing an inflexed longitudinal appendage. Berry with five ſeeds.

Obſ. Schreber, p. 826, ſuſpects this genus not to be diſtinct from *Aralia*, but the habit confirms Juſſieu's opinion, who ſeparates them widely. Two ſpecies are deſcribed by Aublet.

1. G. *glabrum*. (Goupia glabra; Aubl. v. 1. 296. t. 116.)—“ Leaves ſmooth.”—Native of the foreſts of Guiana, 30 leagues from the ſea, bearing flowers and fruit in November. The *trunk* is 60 feet or more in height, and two or three feet in diameter, ſerving to make canoes; the bark ſmooth and grey; the wood white and light. *Branches* drooping, furniſhed with alternate *leaves* of an ovate, pointed, ſomewhat unequal figure, entire, rigid, ſhining, and ſmooth, with a branching rib, and fine tranſverſe veins at the back. *Flowers* yellow, ſmall, many together in ſolitary axillary umbels. *Berry* black, globular.

2. G. *tomentoſum*. Willd. Sp. Pl. v. 1. 1522.—“ Leaves downy.”—Native of the foreſts of Cayenne and Guiana. Not half ſo lofty as the former. The *bark* is wrinkled and dark-coloured. *Leaves* clothed on both ſides with ſome ſhort hairs. Their juice, which, as well as the bark, is bitter, is uſed to cure inflammations of the eyes.

GLOSSOPETRA, or Glottopetra, in *Natural Hiſtory*, called alſo *ichthyodontes*, *ſhark's teeth*, *dog-fiſh's teeth*, &c. a kind of extraneous foſſil, ſomewhat in form of a ſerpent's tongue; frequently found in the iſland of Malta and divers other parts. Some of them are in a high ſtate of preſervation, having their enamel and points perfect, and their ſharp edges finely ſerrated as in the recent teeth.

Naturaliſts have been much divided as to the nature and origin of theſe bodies. Steno, De Corpore ſolido intra ſolidum contento; Ol. Wormius, Diſſert. de Gloſſopetra; and Reyſchius, De Gloſſopetris Lunebergenſibus, treat of them at large.

The vulgar notion is, that they are the tongues of ſerpents petrified; and hence their name, which is a compound of γλωσσα, *tongue*, and πετρα, *ſtone*. Hence, alſo, their traditionary virtue in curing the bites of ſerpents.

The general opinion of naturaliſts is, that they are the teeth of fiſhes, left on land by the waters of the deluge, and ſince petrified.

They even ſpecify the very kind of fiſh, and take it to be that which Theophraſtus and the Greek writers call καρχαρίας, and the moderns the *ſhark* or *ſea-dog*.

Camerarius cannot perſuade himſelf that the gloſſopetræ found in England, Malta, and round Montpelier, were ever the teeth of a ſea-dog, or any other fiſh. The chief difficulty, he ſuggeſts, is the ſmall quantity of volatile ſalt and oil which they afford by diſtillation. To which Dr. Woodward anſwers, in defence of the common ſyſtem, that having lain ſo long buried under ground, it is no wonder they ſhould have loſt the beſt part of their volatile principles. It is certain, that human bones and ſkulls, long interred, do not afford nearly the quantity of thoſe principles that they would have done immediately after the perſon's death.

Another ſcruple, propoſed by Camerarius is, that the gloſſopetræ, when expoſed to the naked fire, turn to a coal; and not to a calx; contrary to what is aſſerted by Fabius Columna. Dr. Woodward anſwers, that it is likely enough the gloſſopetræ, in burning, may aſſume the form of a coal, before it arrive to that of a calx.

The ſeveral ſizes of the teeth of the ſame ſpecies, and thoſe of the ſeveral different ſpecies of ſharks, afford a vaſt variety of theſe foſſil ſubſtances. Their uſual colours are black, blueiſh, whitiſh, yellowiſh, or brown; and in ſhape they uſually approach to a triangular figure. Some of them are ſimple; others are tricuſpidate, having a ſmall point on each ſide of the large one; many of them are quite ſtraight, but they are frequently found crooked, and bent in all directions; many of them are ſerrated on their edges, and others have them plain: ſome are undulated on their edges, and ſlightly ſerrated on theſe undulations. They differ alſo in ſize as much as in figure; the larger being four or five inches long, and the ſmaller of leſs than a quarter of an inch.

They are moſt uſually found with us in the ſtrata of blue clay, though ſometimes alſo in other ſubſtances, and are frequent in the clay-pits of Richmond and of Sheppy iſland, and in other places. They are very frequent alſo in Germany, but nowhere ſo plentiful as in the iſland of Malta. In the Britiſh ſtrata they rarely occur. Mr. Farey has found them in theſe ſtrata only in five places, *viz.* in the London clay, probably obtained from the clay-pits above-mentioned; in a bed of the ſoft or upper chalk in Kent, at Harefield, near New Malton, &c.; in a green ſandy ſtratum below the chalk, N. of Dunſtable, &c.; in the Stonesfield and Collyweſton ſlate ſeries, above the Bath free-ſtone rocks, at Enſtone in Oxfordſhire, where Woodward procured ſpecimens of theſe teeth in the jaw, &c.; and in the thick grey lime-rock which lies under and ſurrounds the South-Wales coal baſons (Phil. Tranſ. N° 334.) Gloſſopetræ are ſometimes found in gravel-pits and other collections of alluvial matters. It is ſeldom poſſible to determine to what place in the ſeries of ſtrata theſe belong, and they ſhould therefore be carefully diſtinguiſhed from ſuch as are actually found in the ſtrata.

The Germans attribute many virtues to theſe foſſil teeth; they call them cordials, ſudorifics, and alexipharmics: and the people of Malta, where they are extremely plentiful, hang them about their children's necks to promote dentition. They may poſſibly be of as much ſervice this way as an anodyne necklace; and if ſuſpended in ſuch a manner that the child can get them to its mouth, may, by their hardneſs and ſmoothneſs, be of the ſame uſe as a piece of coral. See Serpent's *Tongues*.

GLOSSO-PHARYNGEUS, in *Anatomy*, from γλωσσα, *the tongue*, and φαρυγξ, a name given to thoſe fibres of the conſtrictor pharyngis ſuperior, which ariſe from the ſide of the tongue.

GLOSSO-SPATHA, in *Surgery*, an inſtrument, called by ſome *ſpeculum linguæ*, and uſed to depreſs the tongue, in order to look into the fauces.

There are many inflammatory diſorders of the mouth, fauces, and palate, which require a depreſſion of the tongue, while they are inſpected and treated with proper remedies. The handle of a ſilver ſpoon is made to ſupply the place of this inſtrument in moſt caſes, and anſwers the purpoſe very well. Whichever is uſed, care ſhould be taken to depreſs very gently, to avoid giving the patient pain, as alſo to avoid irritating the mouth and inflamed parts.

When injections are to be made into the mouth, this inſtrument or the ſpoon ſhould alſo be applied, and the ſyringe ſhould be conveyed into the mouth over it.

GLOSSO-STAPHYLINUS, in *Anatomy*, from γλωσσα, *the tongue*, and σταφυλη, *the uvula*, another name for the conſtrictor iſthmi faucium. See Deglutition.

GLOTTIDIS Rima, the ſame opening as the glottis. The term rima particularly denotes its ſlit-like form.

GLOTTIS, from γλωττα, *the tongue*, is the opening through which the air paſſes to and from the lungs in reſpiration. In this paſſage the voice is formed. See Deglutition and Larynx.

Julius Pollux makes the glottis a joint or part of a flute, and Heſychius ſays that the glott were little tongues, acted upon by the breath of the player. This deſcription of Heſychius ſeems to confirm the idea of the ancient nominal flutes being a kind of hautboys.

Glottis, in *Ornithology*, a name given by many authors to a bird of the long-legged kind, approaching to the nature of our red-ſhank, but larger and longer legged, and generally known by the name *limoſa*. See Scolopax *Glottis*.

GLOUCESTER, in *Geography*, a city in Glouceſterſhire, England, is ſituated in a vale, on a gentle eminence, riſing, on the eaſt ſide, from the river Severn. This opulent city appears to have originated in a Roman ſtation which was ſituated at King's Holm, near the north-eaſtern extremity of the preſent city. The Romans continued to occupy this ſpot till the diſtractions of their own empire occaſioned them to quit the iſland. Its government then reverted to the Britiſh princes, under whoſe domination it continued till about the year 577, when, according to the Saxon Chronicle, it was ſurrendered to the Weſt Saxons, and was reputed one of their principal cities: it was afterwards ſubjugated by the Mercians, who alſo obtained poſſeſſion of the other parts of the county. Under the Saxons it acquired the appellation of Gleau-ceſtre. The ſtrength and conſequence of the city rendering it an object of frequent enterpriſe, its vicinity was ſeveral times the ſcene of action between the Britons and Saxons. By theſe conflicts, its buildings were nearly ruined; and the whole place might have ſunk into complete decay, if Wolphere, ſon of king Penda, had not enlarged and adorned it, about the year 679. This reſtoration was ſo perfect, that Bede informs us, it was eſteemed, about the commencement of the 8th century, as one of the nobleſt cities in the kingdom. Its early importance is evinced by its having been the reſidence of various Saxon monarchs; and hence it was denominated a royal city, as it is expreſsly termed in a grant made by king Edgar to the monks of Worceſter, dated at Glouceſter in the year 964. By this monarch a battle was fought here with the Danes, who had twice plundered the city in the preceding reigns, and who again ravaged, and partly conſumed it by fire, in that of his ſon Ethelred. Several of the Norman and Engliſh kings alſo occaſionally reſided and tranſacted public buſineſs in this city. A memorable era in the eventful hiſtory of Glouceſter originated in a conteſt between Henry III. and the barons. That monarch, in 1263, appointed ſir Maci de Beſile, a French knight, ſheriff of the county, and conſtable of the caſtle within the city. The preference thus given to a foreigner was violently reſented by the indignant nobles, who immediately made choice of ſir William Tracy, a native of the ſhire. He accordingly proceeded to exerciſe the duties of his office in holding a county court, but was ſuddenly interrupted by De Beſile, who, entering with a party of the king's troops, ſeized the knight, and, with circumſtances of peculiar cruelty, hurried him to the caſtle, where he was committed to cloſe confinement. After this outrage, the barons deputed ſir Roger de Clifford, and ſir John Giffard, with their dependants, to beſiege the caſtle, for the double purpoſes of reſcue and revenge; in a few days they obtained an entrance, and compelled De Beſile to retire to the keep; he afterwards ſurrendered, and was ſent as a priſoner to Erdeſley caſtle, in the marches of Wales. In the year 1278 Edward I. aſſembled a parliament here, and ſeveral laws, connected with the ſtatute of Quo Warranto, were enacted, and have, from that period, been known under the general appellation of the Statutes of Glouceſter. In the courſe of the two next centuries, four parliaments were held here. The oppoſition of the Glouceſtrians to the royal cauſe, during the reign of Charles I., is generally ſuppoſed to have operated fatally againſt his intereſt throughout the kingdom: ſo early as the year 1641, they declared for the parliament; raiſed a company of volunteers, which they added to their trained bands; procured cannon from London and Briſtol, and repaired and ſtrengthened the fortifications: though frequently beſieged by the royaliſts, they ſucceſsfully reſiſted every attack.

The eccleſiaſtical ſtate of Glouceſter, during the Roman and former part of the Saxon period of its hiſtory, is involved in much obſcurity: but in the year 657, Edwy, king of Northumberland, having ſubdued Mercia, erected Litchfield into a biſhop's ſee, and included Glouceſterſhire within its dioceſe. This biſhopric was ſoon afterwards divided into the five ſmaller of Litchfield, Dorcheſter, Leiceſter, Hereford, and Worceſter; to the laſt of which this diſtrict was annexed, and continued ſubject, till the reign of Henry VIII., who, by letters patent, dated September 3d, 1541, and afterwards confirmed by act of parliament, erected "the city of Glouceſter, the county of that city, and all the county of Glouceſter, into a biſhopric, with a dean and chapter, by the name of the dioceſe of Glouceſter; and ordained that ſuch part of the then vill and county of Briſtol, as formerly was in the dioceſe of Worceſter, ſhould be from thenceforward in the dioceſe of Glouceſter for ever." The church appointed for the cathedral of the new ſee, was that belonging to the abbey, founded by Wolphere, firſt Chriſtian king of Mercia, and Ethelred, his brother and ſucceſſor, in the year 681. The New Minſter, as it is termed in the records, was burnt, with the monaſtery, in 1087 or 1088; probably at the ſame time that the city was partly deſtroyed by the adherents of Robert, brother to William Rufus. Serlo, then abbot, began a new church in June, 1089; the firſt ſtone was laid by Robert, biſhop of Hereford; and on the completion of the edifice, in the following year, it was dedicated to St. Peter, by the biſhops of Worceſter, Rocheſter, and Bangor. The abbey was again deſtroyed by fire in 1101 or 1102, but the church was ſaved. The preſent magnificent and intereſting edifice has been erected at different periods, and conſequently diſplays various ſpecimens of ancient eccleſiaſtical architecture, in the Saxon, Norman, and Engliſh ſtyles. The converſion of the abbey church into a cathedral was the chief cauſe of its preſervation at the reformation; and, to the honour of the inhabitants of Glouceſter, it became the object of their peculiar care during the civil wars, after which they obtained a grant of it from Oliver Cromwell. Hence the cathedral has been transferred to the preſent age, as nearly perfect in all its parts, with regard to its general conſtruction, as it was left by the moſt favoured of its architects. The eras of erection of the principal parts are known; and hence the characteriſtic ſtyles of each can be ſatisfactorily aſcertained. The lower part of the nave, the chapels that ſurround the choir, and the crypt, are preſumed to have belonged to the building erected by biſhop Aldred, before 1089: the roof of the nave obtained its finiſhing and form in 1248. In 1310 the ſouth aiſle was begun; and part of the ſouth tranſept was added in 1330. The building of the north tranſept and choir commenced about the ſame year; the latter was completed in 1457. Between the years 1351 and 1390, the elaborate cloiſters were finiſhed. The chapel of our Lady was built between the years 1457 and 1498; and the centre tower between 1457 and 1518. The interior of this ſplendid fabric conſiſts of a nave, choir, ſide aiſles, and tranſepts, with a chapel of our Lady, and ſeveral ſmaller chapels or oratories. From the interſection of the nave and tranſepts riſes a high tower, and on the ſouth ſide is a handſome projecting porch. The roof is ſuſtained on twenty-eight columns, which extend in two rows from the weſt end to the high altar, where the preſbytery forms nearly a ſemi-circular ſweep: the tranſepts have no iſolated pillars. The chapel of our Lady is, as uſual, attached to the preſbytery; and there are chapels in the north-eaſt and ſouth-eaſt angles of the tranſepts and choir, with two others projecting in the ſweep between thoſe and the chapel of our Lady. The outline, or ground plan of the cathedral, is probably the ſame at preſent as deſigned by biſhop Aldred previous to the year 1089; and the crypt remains almoſt as perfect as the maſons left it. The architecture of this ſubterraneous and gloomy place is maſſy, and ſuited to the immenſe weight reſting on the arches, which are turned upon huge ſhort pillars, and ſtrengthened by groins of proportionate ſolidity. The nave is an intereſting ſpecimen of the ſtyle which continued to prevail for nearly two centuries after the Norman conqueſt. The arcade of ponderous round columns, and the rows of ſemi-circular arches above, impreſs the mind with ideas of the ſtrength, ſolidity, and profound ſolemnity which muſt have accompanied its original ſtate. The architecture of the weſt end is very different from the other parts of the nave; and the vault is covered by interſecting ribs, and ornamented key-ſtones; but the remainder is of the plaineſt deſcription, with three ribs only to each pillar; yet the key-ſtones are carved. On each ſide are eight maſſive columns; the arches between them are bounded by large mouldings, carved into zig-zags, and other ornaments. Directly over each column, and at ſome diſtance, is a range of heads of various characters; ſome ſerene, and others terrific. Theſe ſerve as brackets to cluſters of ſhort pillars, whoſe capitals diſplay the moſt beautiful variety of foliage, on which zig-zag ſtrings extend, ſerving as a baſe to other cluſtered pillars with equally elegant capitals: from thoſe the ribs of the vault commence. The gallery windows, pierced through the wall above the arches, are divided by ſhort thick pillars, and bounded by others, with zig-zag arches: a twiſted ſtring ſeparates them from the clereſtory windows. The north and ſouth aiſles of the nave are nearly in the ſtyle of the weſt end, with pointed windows, rich ramifications in the arches from the mullions, and fillet-ed vaults. The arch of entrance to the cloiſters from the north aiſle is moſt elaborately and exquiſitely adorned by pillars, buttreſſes, niches, pinnacles, foliage, and pannels, and the ſingular ornament of twiſted pinnacles under the arch. In the ſouth aiſle, nail-headed mouldings are introduced as embelliſhments on each ſide of the windows. An advanced gradation of ſtyle is exhibited in the interior of the ſouth tranſept; but the moſt perfect and ornamental degree is diſplayed in the chapel of our Lady. The choir is divided from the nave by a ſkreen, deſigned by Kent.

The dimenſions of the cathedral and its ſeveral parts are as follow: entire length, inſide, four hundred and twenty-three feet: length of the nave, one hundred and ſeventy-one feet; breadth, forty-one feet two inches; height, ſixty-ſeven feet ſeven inches: breadth of the north aiſle, twenty feet ten inches; height, forty feet ſix inches: breadth of the ſouth aiſle, twenty-two feet; height, forty feet: length of the ſouth tranſept, ſixty-ſix feet; breadth, forty-three feet ſix inches; height, eighty-ſix feet: length of the north tranſept, ſixty-ſix feet; breadth, forty-three feet ſix inches; height, ſeventy-eight feet: length of the choir, one hundred and forty feet; breadth, thirty-four feet ſix inches; height, eighty-ſix feet: length of our Lady's chapel, ninety-two feet; breadth, twenty-four feet four inches; height, forty-ſix feet ſix inches: height of the tower, including the pinnacles, two hundred and twenty-five feet. The great cloiſters, which were completed by abbot Frouceſter, are the moſt elegant and perfect of the kind: the ſides and roof are profuſely embelliſhed, and the windows are filled with mullions and tracery.

This cathedral contains ſeveral curious ſpecimens of monumental ſculpture. On the tomb of Edward II., which was erected by his ſon and ſucceſſor, and exhibits great perfection of art, is a recumbent figure, in alabaſter, of the deceaſed monarch, regally robed and crowned. Another monument, worthy of notice, is that to the memory of alderman Blackleach, and his wife, whoſe figures, in white marble, lie on a table tomb, dated 1639, and ſeem accurate copies of the portraits by Vandyck: they are evidently the work of a ſkilful artiſt. A third, deſerving obſervation for its deſign and claſſic ſtyle, diſplays a group by Flaxman, erected to commemorate Mrs. Morley, who died at ſea, in childbed: ſhe is repreſented as riſing from the waves with her infant in her arms, and conducted by two angels. Between the north aiſle and the choir is a monument, erected by abbot Parker to perpetuate the memory of king Oſric: and in a chapel nearly oppoſite, is a figure, ſuppoſed to repreſent the unfortunate Robert Curtois, duke of Normandy, and eldeſt ſon of William the Conqueror.

The walls that ſurrounded Glouceſter are mentioned in an ancient prophecy, attributed to Merlin; and tradition aſcribes them to Ciſſa, the ſecond king of the ſouth Saxons. The Norman conqueror cauſed them to be ſtrengthened and embattled: and they were again repaired in the nineteenth of Edward III. Leland deſcribes Glouceſter as "well-builded of tymbre, and ſtrongly defended with walles, where it is not fortified with the deepe ſtreame of Severn water." The walls were completely demoliſhed after the Reſtoration; and the only memorial of their former ſtrength now remaining is the Weſt Gate: this is embattled; and was erected in the time of Henry VIII. The caſtle, was probably built about the period of the Norman invaſion; the remains were lately deſtroyed; and on its ſcite was built the county gaol, which was completed in 1791: it conſiſts of three diviſions, reſpectively named the Penitentiary Houſe, the Bridewell, and the Sheriff's Priſon: theſe all have their diſtinct and appropriate regulations. The gaol contains 203 ſeparate cells; 164 for ſleep, and 39 for employment.

In this city and its ſuburbs were formerly eleven parochial churches: but only ſix are now ſtanding; thoſe of St. Michael, St. Mary de Crypt, St. Nicholas, St. Mary de Lode, St. John, and St. Aldate; the others having been either deſtroyed at the ſiege in 1643, or ſince taken down. In St. Michael's pariſh is a Blue Coat hoſpital, ſo called from the ſimilarity of its regulations to thoſe of Chriſt Church, London, founded and endowed in 1666 by ſir Thomas Rich, bart. Among other benevolent eſtabliſhments that confer honour on the inhabitants of Glouceſter, may be mentioned the county infirmary, erected by voluntary contributions, and opened in the year 1755. Its annual receipts, ariſing from donations and the intereſt of funded property, amount to between two and three thouſand pounds.

The principal trade of Glouceſter reſults from the navigation of the Severn, from the hemp and flax-dreſſing buſineſs, and from the pin manufacture. The latter, which is the principal ſource of labour to the inhabitants, appears to have been introduced into this city by John Tilſby, in the year 1626, and is now carried on to a far greater extent than at any other place in England; there being nine manufactories, which furniſh employment to about 1500 perſons. The pins conveyed annually to the metropolis, are ſaid to amount to the value of 20,000*l.*; but the principal demand is from Spain and America. A bell-foundry has been eſtabliſhed here above three hundred years. The clothing trade, formerly the chief ſupport of the inhabitants, is now nearly loſt: one fulling mill only remains.

Various and important privileges have been granted to Glouceſter by ſeveral monarchs: it was erected into a borough by charter from king John; Henry II. granted the burgeſſes the ſame liberties and cuſtoms as had been enjoyed by the citizens of London; by the act 33 Hen. VIII., which eſtabliſhed the biſhopric of Glouceſter, it is ordered that the town ſhould thenceforth be termed a city. It is alſo privileged as a county within itſelf. The corporation, acting under a charter of Charles II., conſiſts of a mayor, twelve aldermen, a high ſteward, recorder, town clerk, two ſheriffs, common-council, &c. The title of mayor firſt occurs in the year 1483. The high ſtewards have generally been perſons of great eminence. Two repreſentatives to parliament are elected by the inhabitants and freemen; the number of voters is about 3,000; the earlieſt return was made in the twenty-third year of Edward I. The elections are carried on in an ancient ſtructure, called the Booth-hall, which is alſo appropriated to the aſſizes and other county buſineſs. The public affairs of the city are tranſacted at the Tholſey, a building ſuppoſed to have derived its name from the toll formerly received in it by the lords of the manor. Very conſiderable improvements have been made, within the laſt ſeventy years, in the appearance and buildings of this city. It conſiſts, principally, of four ſpacious ſtreets, meeting each other at right angles, and taking their names from the ſituation of the gate which originally ſtood at the bottom of each, as Eaſt Gate ſtreet, Weſt Gate ſtreet, North Gate ſtreet, and South Gate ſtreet. At the interſection of the ſtreets, formerly ſtood a large and beautiful croſs; but falling to decay, and impeding the paſſage of carriages, it was removed in 1750: its ſcite ſtill retains the name. The city is well paved and lighted: and its elevated ſituation, with a gradual deſcent on every ſide, greatly contributes to health and cleanlineſs. The markets had long been eſtabliſhed by preſcriptive right; but thoſe now held, on Wedneſdays and Saturdays, were chartered by Henry III. Three fairs are held annually and much frequented. The houſes and population have varied conſiderably in different ages, according to the degree of ſecurity or danger which the inhabitants experienced: the progreſs has been ſeveral times interrupted by fires and civil commotions. Since the ſiege in 1643, the increaſe has been regular. On the laſt enumeration, under the act of 1801, the houſes, in the city alone, amounted to 1368, the population to 7265: the inhabitants of the ſuburbs being 1500 more. Glouceſter is ſituated 106 miles W. from London.

Among the more eminent natives of this city is Robert of Glouceſter, who wrote a chronicle of Britain in verſe, from the age of Brutus to his own time, the reign of Henry III.

On the north-weſt ſide of Glouceſter is the celebrated iſle of Alney, a ſmall tract, formed by the ſeparation of the ſtream of the Severn into two channels. This was the ſcene of a combat between Edmund Ironſide and Canute the Dane, in the year 1016.

In the ſouthern ſuburbs of Glouceſter are the remains of Lanthony priory, founded in 1187. After the diſſolution, the monaſtic buildings were converted into the offices of a farm. The only parts now left are a large barn, and the principal entrance, or gateway; on which are the arms, among others, of the Bohuns, earls of Hereford, who were great benefactors to the priory. Rudder's Hiſtory, &c. of Glouceſter. Beauties of England and Wales, vol. v.

Gloucester *and Berkley Canal*, is the parliamentary name of a canal of very large dimenſions, following the E. ſide of the Severn river between Berkley and Glouceſter, of which Mr. Robert Mylne and Thomas Dadford were the engineers; the other particulars will be found in our article Canal.

Gloucester, or *Cape Ann*, a townſhip of America, in Eſſex county, Maſſachuſetts, whoſe eaſt point forms the N. ſide of the bay of Maſſachuſetts. It contains 5313 inhabitants, and is divided into five pariſhes, beſides a ſociety of Univerſaliſts. It is a poſt-town and a town of entry. The harbour is open and acceſſible to large ſhips, and it is one of the moſt conſiderable fiſhing towns in the commonwealth. At the harbour, properly ſo called, are fitted out annually from 60 to 70 bankers, and from Squam and Sandy bay, two ſmall out-ports, the bay fiſhery is carried on with great ſpirit, and to a large amount. Thatcher's iſland, on which are two lights, lies cloſe to the S.E. ſide of the townſhip, which is itſelf joined to the continent by a bank of ſand, that is rarely overflowed with the water. Here is a fine white ſand, fit for the manufacture of glaſs. The harbour is defended by a battery and citadel erected in 1795:—16 miles N.E. by E. of Salem, and 34 N.E. of Boſton.

Gloucester, the N. weſternmoſt townſhip, and the largeſt, in Providence county, Rhode iſland, being 11½ miles ſquare, containing 4009 inhabitants.

Gloucester, the name of a county in New Jerſey, bounded N. by Burlington county, S. by Salem, Cumberland, and Cape May counties, E. by the Atlantic ocean, and W. by Delaware river. Its length on the Delaware is about thirty miles, and on the ſea it is about 22 miles. Great and Little Egg harbour rivers are both navigable for veſſels of about 200 tons about 20 miles from their mouths. The ſtreams which fall into Delaware river are navigable for ſmall veſſels, a few miles up from their mouths, and afford ſome ſhad, roach, herrings, and perch. Its adjacent iſlands are Red Bank, Pett, and Old Man's creek. The ſoil of the county is a mixture of ſand and loam, and the tract bordering on the Delaware is in a high ſtate of cultivation. The chief productions are beef, pork, fiſh, hay, corn, lumber, butter, cheeſe, &c. It is divided into ten townſhips, *viz.* Woodbury, Waterford, Newtown, Glouceſter townſhip, Glouceſter town, Deptford, Greenwich, Woolwich, Egg harbour, and Galloway. Mulicus river divides the county from Burlington, and is navigable 20 miles for veſſels of 60 tons. Maurice river runs ſoutherly about 40 miles through Cumberland county into Delaware bay, and is navigable for veſſels of 100 tons 15 miles, and for ſhallops 10 miles further. It contains 16,115 inhabitants, of whom 61 are ſlaves. In this county are found quantities of bog-iron ore, which is manufactured into pig and bar iron, and hollow ware. Here is alſo a glaſshouſe. The chief town is Woodbury, nine miles S. of Philadelphia.

Gloucester, a ſmall town in the above-mentioned county, on the E. ſide of Delaware river, three miles below Philadelphia.—Alſo, a poſt-town in Virginia, in the county of its own name, on a point of land on the N. ſide of York river, 17 miles diſtant from York town.

Gloucester, a county in Virginia, fertile and well cultivated, bounded N. by Piankitank river, which ſeparates it from Middleſex, E. by Matthews county and Cheſapeak bay, N.W. by King and Queen, S. and S.W. by York river, which divides it from York county. It is about 55 miles long and 30 broad, and contains 3272 free inhabitants, and 4909 ſlaves. The low lands produce excellent barley, and Indian corn, the ſtaple produce of the county.

Gloucester *Houſe*, a ſtation belonging to the Hudſon-bay company, ſituated in New South Wales, on the N. ſide of the waters which form a communication through a chain of ſmall lakes, between Winnipeg lake and Albany river. Henley houſe lies N.E. of this, nearer the mouth of Albany river in James's bay. N. lat. 54°. W. long 87° 30′.

Gloucester, a townſhip in the county of Dundas in Upper Canada, which is the ſeventh in aſcending the Ottawa river; E. of, and contiguous to, the river Rondeau.

Gloucester, *Cape*, a cape on the S. coaſt of Terra del Fuego.—Alſo, a high promontory on the E. coaſt of New Holland. S. lat. 19° 59′. E. long. 148° 11′.—Alſo, a cape on the coaſt of New Britain. S. lat 5° 54′. E. long. 148° 15′.

Gloucester *Iſland*, an iſland in the S. Pacific ocean, about ſix miles long, and from one to a quarter of a mile broad, diſcovered and ſo called by captain Wallis in 1767. It is ſurrounded by rocks, full of trees, and inhabited by perſons who appeared armed with long pikes or poles, but deſtitute of canoes. S. lat 19° 11′. W. long. 140° 4′.

Gloucester, *Duke of*, *Iſlands*, two iſlands in the S. Pacific ocean, diſcovered and ſo called by Captain Carteret in 1767, which were covered with trees, but appeared to be uninhabited. The ſouthernmoſt of them was a ſlip of land in the form of a half-moon, low, flat, and ſandy; the appearance of it was pleaſant, but it had neither vegetables nor water; but it abounded with birds, ſo tame that they might be taken by the hand. The other iſland very much reſembled this, and is diſtant from it about five or ſix leagues; they lie W.N.W. and E. S. E. of each other. One of them is in S. lat. 20° 38′. W. long. 146°: the other in S. lat. 20° 34′. W. long. 146° 15; the variation 5° E. Theſe iſlands are probably the land ſeen by Quiros, as the ſituation is nearly the ſame.

GLOUCESTERSHIRE, one of the weſtern counties of England, is ſurrounded by Herefordſhire, Oxfordſhire, Berkſhire, Wiltſhire, Somerſetſhire, and Monmouthſhire. It comprehends an area of nearly ſeventy miles in one direction, by forty in a tranſverſe line. This diſtrict, during the Roman domination in Britain, was much occupied by the Romans. Mr. Foſbrooke (one of the hiſtorians of the county) obſerves, "from the ruins which have at various times been excavated, it is evident that this county, from Cirenceſter to Painſwick, Biſley, Sapperton, Woodcheſter, Uley, Kingſcote, and other adjoining places, was much peopled with Romans, or Romanized Britons; that Cirenceſter was the great metropolis, or reſort of pleaſure and amuſement; while Glouceſter, and the hills about the Severn, were the great military poſitions; the city, on account of the river, having peculiar advantages with reſpect to commerce." The principal Roman roads which paſſed through this county, were the Ikenild ſtreet, the Irming or Erming ſtreet, the Foſs-way, and the Via Julia. Under the dominion of the Saxons, Glouceſterſhire formed part of the Mercian kingdom, and Winchcombe and Kingſtanley are mentioned as reſidences of the Anglo-Saxon monarchs. On the diviſion of Mercia into five biſhoprics, after the converſion of the Saxons, the greateſt part of this county was included under that named Wiccia, and from this appellation the Dobuni, the early inhabitants of this part of Britain, were afterwards termed Wiccii. Glouceſterſhire is ſeparated into four diviſions; theſe are ſubdivided into twenty-eight hundreds, containing 320 pariſhes, one city, and twenty-eight market towns. The number of houſes, as returned under the population act, amounted to 37,176; of inhabitants, 187,164; of which 90,237 were males, and 96,927 females. The whole county, with the exception of the chapelries of Icomb, and Cowhonyborn, is included within the dioceſe of Glouceſter; which comprehends one arch-deaconry, and ten deaneries. The number of repreſentatives returned to parliament are eight; two for the ſhire, two for the city, two for Tewkſbury, and two for Cirenceſter. The general aſpect of Glouceſterſhire is greatly diverſified; nature having divided it into three diſtricts of very diſſimilar character, reſpectively named the Hill, the Vale, and the Foreſt. The Hill diſtrict, including the Cotſwolds, and the Stroudwater hills, may be regarded as a continuation of the central chain proceeding ſouth from Derbyſhire, and paſſing through this county with a ſmaller elevation into Wiltſhire; there ſwelling into the Saliſbury Downs, and afterwards running weſt towards the Land's End in Cornwall. The extent of the Cotswold hills, from Broadway hill to near Tetbury, is thirty miles; and from Birdlip hill to Burford, about twenty miles: the area they include is eſtimated, by Mr. Marſhall, to contain nearly 200,000 acres. The ſurface is billowy; and the climature, conſidering the natural elevation of the land, unuſually mild. The ſides of the hills abound with ſprings; and almoſt every dip has its rill, and every valley its brook. The primary object of the Cotſwold huſbandry is ſheep; theſe have been long famous; and it is a prevailing tradition, that the Spaniards originally procured their breed of fine woolled ſheep from theſe hills, though this aſſertion is contradicted by ſeveral modern writers. The incloſures are chiefly ſtone walls, about four feet and a half high, excluſive of a coping of flat ſtones. The Vale diſtrict includes the entire tract bounded on the eaſt by the Cotſwold hills, and by the river Severn on the weſt; and is uſually ſubdivided into the Vales of Eveſham and Glouceſter, and the Vale of Berkeley; the latter of which is ſeparated from the former by a natural interſection, and is very different in produce and rural management. The Foreſt diſtrict is ſeparated from the reſt of the county by the river Severn; and is principally comprehended by the Foreſt of Dean, which was formerly of particular value, for the goodneſs and ſtrength of its timber. Its oaks were ſo greatly renowned that Evelyn obſerves, that in Elizabeth's reign, an ambaſſador was purpoſely ſent from Spain to procure its deſtruction, either by negociation or treachery. It alſo abounds in beech; and the ſoil is conſidered as peculiarly favourable for the growth of the Stire apple. Its principal minerals are iron, ore, and coal: iron appears to have been wrought here even in the time of the Romans; and ſo early as the reign of Edward I. ſeventy-two furnaces, for melting iron, are recorded to have been built here. In a ſurvey made in the ſeventeenth year of Charles I. the foreſt is eſtimated as originally containing upwards of 43,000 acres, of which above 14,000 were woodland. Several thouſand acres have, however, been granted away, by different ſovereigns, and diſafforeſted. The miners have diſtinct courts, and, like thoſe of Derbyſhire and Devonſhire, are governed by their own cuſtoms.

The principal rivers connected with Glouceſterſhire, are the Severn, the Frome, the Wye, and the Iſis or Thames. The canals that interſect the county are diſtinguiſhed by the names of the Thames and Severn, the Stroudwater, the Berkeley, and the Hereford and Glouceſter. The Severn, the ſecond commercial river in England, renders eſſential ſervice to a large portion of this county. It enters Glouceſterſhire near the ancient town of Tewkeſbury, where, uniting its waters with the Upper Avon, and purſuing a ſouth-weſterly courſe, it traverſes a wide vale, which is rich in paſturage, and in ſome places abundantly wooded. About one mile above Glouceſter, it divides into two ſtreams: theſe again unite a little below the city, forming the tract of land called Alney iſland. In the courſe of its paſſage through the county, it receives the ſtreams of the Upper Avon, the Chelt near Wainlode, the Leden near Over's-bridge, the Frome at Framilode, the Avon at Berkeley, and the Lower Avon below Briſtol. The Wye ſeparates part of this county from Monmouthſhire and Herefordſhire, and forms the grand natural weſtern boundary to the foreſt of Dean, whoſe noble wooded eminences conſtitute many fine features on its meandering banks. The Thames, the moſt important of the Britiſh rivers, has its ſource in this county, at a place called the Thames-head, near the village of Cotes, about two miles ſouth-weſt of Cirenceſter. Near this place the Thames and Severn canal emerges from under ground, and receives a conſiderable quantity of water, occaſionally from this ſpring. The junction of the Thames and Severn was an object of favourite ſpeculation with the London and Briſtol merchants for many generations; but was not completed till near the cloſe of the laſt century, an act for that purpoſe was obtained in 1783, and the deſign was brought to perfection in 1792, when the firſt veſſel paſſed from the Severn into the Thames. This canal begins at Wallbridge, near Stroud, (at the place where the Stroud navigation ends,) and proceeds in a devious courſe through the county to Lechlade, where it joins the Thames. This courſe includes a diſtance of thirty miles, ſeven chains and a half. The water, in its progreſs from Stroud to Sapperton, (ſeven miles three furlongs), is raiſed by means of locks 241 feet 3 inches: between Sapperton and Lechlade it falls 130 feet 6 inches. The Stroudwater canal encounters many obſtacles; yet in defiance of all oppoſition, an act was obtained in 1775, under the operation of which it was finiſhed.

The manufactures of Glouceſterſhire are numerous: clothing ſtuffs, blankets, rugs, carpets, ſtockings, &c. are made in different parts of the county. Bar iron, edge tools, wire, nails, and many other articles, are alſo manufactured in large quantities. Near Briſtol are ſome extenſive founderies; as well as different works for making braſs and wire, vitriol, red-lead, ſal-ammoniac, &c. At Glouceſter, vaſt quantities of pins are made; and at Frampton-Cotterel is a conſiderable manufactory of felt-hats. Several authors have employed their pens in deſcribing the topography and antiquities of this county: the principal of theſe are ſir Robert Atkins's "Ancient and preſent State of Glouceſterſhire," fol. 1712, ſecond edit. 1768. Rudder's "New Hiſtory of Glouceſterſhire," fol. 1779: Bigland's "Hiſtorical, Monumental, and Genealogical Collections," &c. folio, one volume and part of a ſecond, 1791: Lyſons's "Collection of Glouceſterſhire Antiquities," folio, 1801: Rudge's "Hiſtory of the County of Glouceſter, compreſſed and brought down to the Year 1803," 2 vols. 8vo. Foſbrooke and Yates's "Hiſtory of Glouceſterſhire," 2 vols. 4to. 1805. "Beauties of England and Wales," vol. v. contains a conciſe and general account of the county.

GLOVE, CHIROTHECA, a habit or covering for the hand and wriſt, uſed both for warmth, decency, and as a ſhelter from the weather.

Gloves are diſtinguiſhed, with reſpect to commerce, into leather gloves, ſilk gloves, thread gloves, cotton gloves, worſted gloves, &c.

There are alſo gloves of velvet, ſattin, taffety, &c. Leather gloves are made of ſhamoy, kid, lamb, doe, elk, buff, &c. There are alſo perfumed gloves; waſhed, glazed, waxed gloves; and white, black, ſnuff-colour, &c. gloves; ſingle, lined, topped, laced, fringed with gold, ſilver, ſilk, fur, &c.

It is a proverb for a glove to be good and well made, three kingdoms muſt contribute to it; Spain to dreſs the leather, France to cut it, and England to ſew it. But, of late, the French ſeem to have appropriated the functions of the other two; the gloves of the French manufacture being now ſaid to have the advantage, in point of dreſſing and ſewing, as much as of cutting.

By 34 Geo. III. c. 10. the Britiſh duty on gloves and mittens impoſed by 25 Geo. III. c. 55. is repealed, except the duty on licenſes; and by 36 Geo. III. c. 80. the ſaid duty on licences is alſo repealed. By 6 Geo. III. c. 19. and 25 Geo. III. c. 55. foreign manufactured leather gloves or mitts ſhall not be imported, under the penalty of forfeiture; and the importer or ſeller incurs, beſides forfeiture, a penalty of 200*l.* with double coſts.

GLOVE, *to throw the*, was a practice or ceremony very uſual among our forefathers, being the challenge whereby another was defied to ſingle combat. It is ſtill retained at the coronation of our kings; when the king's champion caſts his glove in Weſtminſter-hall.

Favyn ſuppoſes the cuſtom to have ariſen from the eaſtern nations, who, in all their ſales and deliveries of lands, goods, &c. uſed to give the purchaſer their glove by way of livery or inveſtiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphraſe calls glove what the common verſion renders by ſhoe. He adds, that the rabbins interpret by glove, that paſſage in the cviiith Pſalm, "In Idumeam extendam calceamentum meum, Over Edom will I caſt out my ſhoe." Accordingly, among us, he who took up the glove, declared thereby his acceptance of the challenge; and as part of the ceremony, continues Favyn, took the glove off his own right hand, and caſt it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each ſide to meet at the time and place which ſhould be appointed by the king, parliament, or judges.

The ſame author aſſerts, that the cuſtom which obtained of bleſſing gloves, in the coronation of the kings of France, is a remain of the eaſtern practice of giving poſſeſſion with the glove. Lib. xvi. p. 1017, &c.

The delivery of a glove was in frequent uſe formerly, as a ſymbol of inveſtiture. See Du Cange, Gloſſ. Lat.

Gloves were alſo uſed to ſignify the ſteward's or bailiff's fee, or part of the price of the inveſtiture or purchaſe-money of the land. "Si aliquam territorii partem venundari contigerit, domini venditiones habebunt; ſcilicet, tot denarios quot venditor inde habuerit ſolidos. Major vero terræ illius pro *wantis* accipient duos donarios." Where *wanti* ſignifies *gloves*, or, in French, *gants*.

Hence the common cuſtom, in many bargains, of giving ſervants money for a pair of gloves.

Anciently it was prohibited the judges to wear gloves on the bench; and at preſent, in the ſtables of moſt princes, it is not ſafe going in without pulling off the gloves.

GLOVER, RICHARD, in *Biography*, was born at London in 1712. He received the elementary inſtructions in claſſical learning at Cheam, and exhibited a conſiderable taſte for the claſſics, and an attachment to ſcience. When he was only 16 years old, he wrote a copy of verſes "To the memory of ſir Iſaac Newton," which is prefixed to Dr. Pemberton's view of the Newtonian philoſophy. He engaged in commercial purſuits, and became eminent in the mercantile world, to which he was introduced by his father. In 1737, he married a lady with a handſome fortune; and in the ſame year he publiſhed his epic poem of Leonidas. Glover had joined the oppoſition of the day, at the head of which was Frederic prince of Wales, and his poem, founded on the ſtruggles of free Greece againſt Aſiatic deſpotiſm, was calculated in a high degree to ſerve a generous cauſe. It abounds in noble ſentiments, and is conſiderably varied by incident and deſcription. Its plan is admirably adapted for poetical effect: it was received by Lyttleton and others with high applauſe, and very ſoon paſſed through three editions. "But it labours," ſays the critic, "under that want of intereſt which attends all modern epics, eſpecially ſuch as are built upon ſome of the ſubaltern events of ancient hiſtory; and its poetry is not of a character ſufficiently elevated to engage the reader by the beauty of detached paſſages." The reputation which it firſt acquired ſoon ſubſided, and it now lives rather in memory than in the actual acquaintance of readers. He publiſhed in 1739, his poem, entitled "London, or the Progreſs of Commerce:" and the ballad of "Hoſier's Ghoſt." Mr. Glover was not only a poet but an ardent politician, and was diſtinguiſhed in various inſtances for his eloquence in the cauſe of freedom. His talents gained him great credit, and he was appointed by the merchants of London to conduct an application to parliament, complaining of the neglect with which their trade had been treated. The ſpeech which he pronounced at the bar of the houſe of commons on this ſubject, in January 1742, was greatly admired, and was publiſhed. His celebrity as a public character, did not favour his progreſs in commerce; his affairs became embarraſſed; he was, to uſe a modern faſhionable phraſe, obliged to ſuſpend his payments, and at length retreated from active life, to practiſe economy in an obſcure ſituation. The ducheſs of Marlborough bequeathed him, and Mallet, five hundred pounds each on condition of their joining to write the hiſtory of the great duke. Glover renounced the taſk, and Mallet never executed it. He now wrote ſeveral pieces for the ſtage, which being ſucceſsful to a conſiderable degree his circumſtances became ſo much improved, that he ventured to return to public life, and ſat as member for Weymouth, in the parliament of 1761. His commercial knowledge made him extremely uſeful on ſeveral important occaſions. In the year 1775, he took an active part in an application to parliament on behalf of the Weſt India merchants, and for his zeal and aſſiduity he was complimented with a valuable preſent of plate. He died in

November 1785, and left behind him another poem, entitled the "Athenaid," relating, in thirty books, the wars between the Greeks and Perſians. This was publiſhed in 1788, in three volumes 12mo., but it failed completely in attracting public attention.

GLOVER, in *Geography*, a townſhip of America, in the ſtate of Vermont and county of Orleans, N. E. of Craftsborough, adjoining. It has 36 inhabitants.

GLOVER'S *Reef*, rocks on the bay of Honduras. N. lat. 16°. W. long. 88° 20'.

GLOW-WORM, in *Entomology*. See CICINDELA. *Cantharis* and *Cicindela* have been often uſed, indiſcriminately, for the glow-worm; but they form two diſtinct genera of the ſame order in the Linnæan ſyſtem. See CANTHARIS. The glow-worm is often ſeen in the day time.

The male and female differ greatly in this ſpecies of inſect. The male has wings, and is a ſmall fly; the female has no wings, but is a large crawling worm.

The body of the male is oblong, and ſomewhat flatted; the wings are ſhorter than the body; the head is broad, dun, and flat; the eyes are large and black. This has no light iſſuing from it, and is not commonly ſuppoſed to be at all of kin to the glow-worm.

The female is what we expreſsly call by this name; this is a very ſlow-paced animal, without wings, and ſomewhat reſembling a caterpillar; the head is ſmall, flat, hard, and black, and ſharp towards the mouth: it has ſhort antennæ, and ſix moderately long legs; the body is flat, and is compoſed of twelve rings, whereas the body of the male conſiſts only of five; it is of a duſky colour, with a ſtreak of white down the back. It is often ſeen in the day-time, but it is not known except in the dark; at which time it is eaſily diſtinguiſhed by the glowing light, or lambent flame, that is ſeen near the tail, iſſuing from the under part of the body.

The common glow-worm is frequently met with under our hedges, and, if carefully taken up, may be kept alive many days on freſh turfs of graſs; all which time it will continue to ſhine in the dark.

The light of this little inſect is ſo ſtrong, that it will ſhew itſelf through ſeveral ſubſtances, in which the creature may be put up; a thin pill-box eaſily ſhews it through, and even though lined with paper, the light is not impeded in its paſſage by both. The creature is ſluggiſh, and appears dead in the day-time, and its light is not diſtinguiſhable, even if carried into a darkened room, unleſs the creature be turned upon its back, and diſturbed, ſo as to be put in motion, and then it is but very faint; after ſun-ſet the light begins to return, and with it the life and motion of the animal. The motion and light of this creature ſeem, in ſome meaſure, to depend upon one another: it never ſhines but when the body is in ſome ſort of motion; and when it ſhines moſt, the body is extended to one-third more than its length in the day-time. In the time of brighteſt ſhining, it will ſometimes on a ſudden turn its body about, and the light will not be larger than the head of a pin; and, on being touched, it will then immediately extend itſelf, and the light will become as large and bright as ever. Phil. Tranſ. N° 71.

Two points ſeem to be agreed upon by naturaliſts, with regard to the light iſſuing from the tail of a glow-worm; firſt, that it is phoſphoric, and ſecondly, that its uſe is to attract the male inſect. Should the ſingularity, if any ſuch there be, in the natural hiſtory of this animal, which ſhould render a proviſion of this kind more neceſſary for the glow-worm, than for other inſects, be a ſubject of inquiry; it may be obſerved that this ſingularity ſeems to be the difference, which ſubſiſts between the male and the female, which difference is greater than what is found in any other ſpecies of animal whatever. The glow-worm, as we have obſerved, is a female caterpillar, the male of which is a fly; lively, comparatively ſmall, diſſimilar to the female in appearance, probably alſo as diſtinguiſhed from her in habits, purſuits, and manners, as he is unlike in form and external conſtitution. Hence it appears, that the caterpillar cannot meet her companion in the air. The winged rover diſdains the ground. They might never therefore be brought together, did not this radiant torch direct the volatile mate to his ſedentary female.

"In this example," ſays the ingenious author now cited, "we ſee the reſources of art anticipated. One grand operation of chemiſtry is the making of phoſphorus; and it was thought an ingenious device, to make phoſphoric matches ſupply the place of lighted tapers. Now this very thing is done in the body of the glow-worm. The phoſphorus is not only made, but kindled; and cauſed to emit a ſteady and genial beam, for the purpoſe which is here ſtated, and which I believe to be the true one." Paley's Natural Theology, p. 363.

GLOW-*worm, Flying, cicindela volans*. In the warmer months of the year, this creature is ſometimes caught in our houſes flying to the flame of a candle, and when examined in the dark, it is found luminous at theſe times, though perhaps leſs, or not at all ſo, at others; which may be a reaſon of its not being known, though caught in the fields; and to this it may be owing, that many who have deſcribed it have thought it not a native of England. Without wings it is frequently enough found in form of the common glow-worm, and then always ſhines. Aldrovand has very well deſcribed the *cicindela volans*, and ſays, that it lays eggs which hatch into ſmall worms, and that theſe after a time become flies, by the ſame ſort of change which happens to caterpillars and other reptiles which become butterflies, and other ſpecies of winged inſects. Mouffett, and Thomas Bartholine, both deſcribe the animal much as Aldrovand has done, but they allow the male only to have wings; but Julius Scaliger contradicts this, and ſays, that he has caught them both winged in the act of generation: this is a plain proof that both ſexes are winged; yet it has not happened that both ſexes have been acknowledged to be ſo, even by thoſe who have quoted this paſſage. And Mr. Waller, who gives an account of them in the Philoſophical Tranſactions, obſerved them in the ſame manner in the act of copulation both winged, and with no other difference between them but that the female was the larger of the two, which is the caſe in regard to many inſects. Julius Scalig. Exerc. 191. Phil. Tranſ. N° 167, p. 841.

The male and female in this winged ſtate both ſhine in hot weather, and their light is ſo vivid as to be eaſily ſeen even while there is a candle in the room; the vibrations of it are irregular and its colour greeniſh. The luminous parts are two ſmall ſpecks under the tail at the end, and the light continues in theſe ſome time after the tail is cut off, but then gradually goes out.

The parts of inſects continue alive in ſome degree for a conſiderable time after they are cut off, and probably the light in the tail of this animal continues juſt as long as that ſort of life remains in it. Mouffett, cap. 15.

The uſe of this light ſeems to be to direct the animal in its courſe, and in the taking of its prey, and to this purpoſe it is admirably placed. The tail is eaſily bent under the belly, and then throws the light full upon any object about or under the head of the animal, and the eyes are placed not on the upper part but on the under ſide of the head; ſo that they have all the advantages of it, while the light in this part is not offenſive to the eyes, as it naturally would have been if carried before the head. The creature can, upon occaſion, cover this light, ſo as not to be known, or purſued by it, by its enemies. Thomas Barthol. de Luce Anim. lib. ii. cap. 12.

This inſect is of the beetle kind, of a brown and duſky colour. It has hard caſe or ſhell wings, as the other beetles have, and when theſe are expanded, there appear a pair of very large membranous ones; its head is covered with a ſort of ſhield or broad-brimmed hat: under this hat are placed the eyes, which are black and large, and are moveable, ſo that the creature can, upon occaſion, thruſt them forward: it has two hairy antennæ, and its legs are like thoſe of the common fly, hard, ſhelly, and hairy. Its eyes afford an elegant object for the microſcope, being compoſed of an infinite number of lenſes, as thoſe of the libellæ and other inſects. Aldrovand. de Inſect. lib. i. cap. 8.

GLOXINIA, in *Botany*, named by the late M. L'Heritier in honour of Dr. Benjamin Peter Gloxin, a native of Colmar, in whoſe inaugural diſſertation, publiſhed at Straſburg in 1785, are given the characters of *Martynia* and ſome neighbouring genera, among which the plant now under our conſideration is comprehended. The ſame work alſo contains the firſt deſcription and figure of the *Salvia leonuroides*, unneceſſarily changed by L'Heritier afterwards to *S. formoſa*; and one of *Cyperus ægyptiacus*, which proved the *Schœnus mucronatus* of Linnæus. L'Herit. Stirp. Nov. 149. Ait. Hort. Kew. v. 2. 331. Willd. Sp. Pl. v. 3. 229. Mart. Mill. Dict. v. 2. Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Campanulaceæ*, Juſſ.? or rather a new order, diſtinguiſhed by lateral, not marginal, receptacles of the ſeeds. *Juſſ.*

Gen. Ch. *Cal.* Perianth ſuperior, of five oblong, ſpreading, nearly equal leaves. *Cor.* of one petal, obliquely bell-ſhaped; gibbous at the baſe; its border in five rounded obtuſe lobes, the four uppermoſt recurved, the lower one prominent, concave and inflexed. *Stam.* Filaments four, much ſhorter than the corolla, with the rudiment of a fifth; inſerted into the receptacle, connected with the baſe of the corolla, incurved, downy, converging laterally in the upper part, two of them rather the ſhorteſt; anthers ovate, peltate, two-celled, cohering together, their lobes diverging. *Piſt.* Germen inferior, turbinate, furrowed; ſtyle cylindrical, as long as the ſtamens; ſtigma capitate. *Peric.* Capſule imperfectly two-celled, with two valves, and two lateral divided receptacles. *Seeds* numerous.

Eſſ. Ch. Calyx ſuperior, of five leaves. Corolla bell-ſhaped, with an oblique irregular border. Filaments, with the rudiment of a fifth, inſerted into the receptacle. Capſule with many ſeeds, inſerted into lateral receptacles.

1. G. *maculata.* Curt. Mag. t. 1191. (Martynia perennis; Linn. Sp. Pl. 862. Hort. Cliff. t. 18. Ehret. Pict. t. 9. f. 2. Mart. Mill. Dict. v. 3.—Native of South America; the ſeeds having been ſent from Carthagena by Mr. Robert Millar, before 1739. It requires with us the conſtant heat of a bark ſtove, by means of which it flowers late in autumn. It is propagated abundantly by the little tuberous *roots*, which are perennial. The *ſtem* is herbaceous, ſimple, leafy, round, very ſmooth, ſpotted with purple. *Leaves* large, oppoſite, recurved, ſtalked, broad-ovate, acute, ſerrated, ſmooth and ſhining, pale at the back, with prominent veins. *Flowers* axillary from the diminiſhed leaves, or bracteas, at the upper part of the ſtem, ſolitary, ſtalked, large, drooping, of a fine blue with a dark ſpot at the bottom within. Their ſcent is very peculiar, reſembling mint, which no writer ſeems to have noticed.

GLUBOKAIA, in *Geography*, a town of Ruſſia, in the government of Kolyvan; 72 miles E. of Semipolatnoi.

GLUCHOV, or GLUKHOF, a town and diſtrict of Novogorod Severſkoi, ſituated on the river Yeſma, falling into the Seim; 40 miles E.S.E. of Novogorod Severſkoi.

GLUCK, *le Chevalier* CHRISTOPHER, in *Biography*, a muſical compoſer of great fire and originality, who, during the laſt 30 or 40 years of the preceding century, acquired great renown, but chiefly in France, by a ſpecies of compoſition, congenial to the national taſte, which Lulli and Rameau had formed, and in which the ſhort and ſimple airs required no great abilities in the ſingers; but the dramas being written in the language of the country, and the poet being regarded as a much more important perſonage than the compoſer of the muſic, the ſeveral characters required great actors rather than great ſingers.

This eminent compoſer was born in the Palatinate, of a poor family, about the year 1716. His father, during the infancy of his ſon, removed into Bohemia, where he died, leaving his offspring in early youth, without any proviſion, ſo that his education was totally neglected; but nature had given him an inſtinctive love for muſic, which is taught to all children, with reading and writing, in the Bohemian ſchools, whether of charity or ſuperior foundations, in all the towns and villages; in churches and in the ſtreets, men, women, and children ſing in parts, and play upon ſome inſtrument, and often on many inſtruments. This was the caſe with the young Chriſtopher, who travelled about from town to town, ſupporting himſelf by his talents till he had worked his way to Vienna, where he met with a nobleman who became his patron, took him into his ſervice, carried him into Italy, where he procured him leſſons in counterpoint, at Naples, by which he profited ſo well, that before he left Italy he compoſed ſeveral dramas for different theatres, which acquired him reputation ſufficient to be recommended to lord Middleſex as a compoſer to our lyric theatre in the Haymarket, then under his lordſhip's direction. But, unluckily, arriving in England in 1745, after his firſt opera of "Artamene" had been performed ten nights, in which the famous air "Raſſerena il meſto ciglio," ſung by Monticelli, was conſtantly encored, the rebellion broke out, and the great Opera-houſe was ſhut up, on account of the popular prejudice againſt the performers, who, being foreigners, were chiefly Roman Catholics. Nor was the Opera-houſe allowed to be opened again, till January 7th, 1746, when "la Caduta de' Giganti," ſet by Gluck, was performed before the duke of Cumberland, in compliment to whom the whole was written and compoſed. The ſingers were Monticelli, Jozzi, and Ciacchi; with ſignora Imer, Pompeati, afterwards better known by the name of madame Cornelie, and Fraſi. The firſt woman, Imer, never ſurpaſſed mediocrity in voice, taſte, or action; and the Pompeati, though nominally ſecond woman, had ſuch a maſculine and violent manner of ſinging, that few female ſymptoms were perceptible. The new dances by Auretti, and the charming Violetta, afterwards Mrs. Garrick, were much more applauded than the ſongs, which, however, for the time, had conſiderable merit. The firſt air in G. minor is of an original caſt. but monotonous. The ſecond air has genius and deſign in it. Then a duet, in which he hazarded many new paſſages and effects. The following air, for Monticelli, is very original in ſymphony and accompaniments which a little diſturbed the voice-part in performance, we well remember, and Monticelli called it *aria tedeſca.* His contemporaries in Italy, at this time, ſeemed too much filed down; and he wanted the file, which, when uſed afterwards in that country, made him one of the greateſt compoſers of his time. The next air printed, is in a very peculiar meaſure, and like no other that we recollect: it has great merit of novelty and accompaniment; the voice-part wants only a little more grace and quiet. The following ſong, ſet for Jozzi, a good muſician with little voice, is full of new and ingenious paſſages and effects; we ſhould like much to hear this air well performed at the opera; it is kept alive from beginning to end. Something might be expected from a young man able to produce this opera, imperfect as it was. It had, however, but five repreſentations.

From London he returned to Italy, and compoſed ſeveral operas in the ſtyle of the times, ſuch as that of Terradeglas, Galuppi, and Jomelli; and we heard little of him till he enliſted with the Italian poet Calſabigi, with whom he joined in a conſpiracy againſt the poetry and muſic of the melo-drama then in vogue in Italy and all over Europe.

It is extraordinary that Calſabigi, editor of the beautiful Paris edition of the works of Metaſtaſio in 1755, in the preface to which there is the higheſt and ſeemingly moſt cordial praiſe of the works of the imperial laureate, ſhould be the firſt, ten years after, to find them ſo defective; writing his "Orfeo" in a different ſtyle, and joining with Gluck in decrying the lyric ſtyle both of the muſic and poetry of the Italian opera.

In 1764, the year in which the late emperor Joſeph was crowned king of the Romans, Gluck was the compoſer, and Guadagni the principal ſinger. It was in this year that a ſpecies of dramatic muſic, different from that which then reigned in Italy, was attempted by Gluck in his famous opera of "Orfeo," which, with Guadagni's admirable action, ſucceeded ſo well, that it was ſoon after attempted in other parts of Europe, particularly at Parma and Paris. This is not the place to diſcuſs its merit; we ſhall here only obſerve, that the ſimplifying dramatic muſic in Gluck's manner, in favour of the poet, at the expence of the compoſer and ſinger, is certainly very rational, where an opera is performed in the language of the country, and the ſingers have no great abilities to diſplay, as in France; but in England, where we have frequently ſingers of uncommon talents, and where ſo ſmall a part of an opera audience underſtands Italian, by abridging the ſymphonies, and prohibiting diviſions and final cadences, in favour of an unintelligible drama, we ſhould loſe more than we ſhould gain.

After its ſucceſs at Parma and Paris, "Orfeo" was exhibited at Bologna, Naples, and in 1770 in London; when the principal parts were filled by Guadagni and Graſſi, afterwards Mrs. Bach.

The unity, ſimplicity, and new dramatic excellence, which at Vienna, and afterwards at Paris, rendered this drama ſo intereſting as to make the audience think more of the poet than the compoſer, were greatly diminiſhed here, by the heterogeneous mixture of muſic of other compoſers in a totally different ſtyle.

In 1769, Calſabigi and Gluck, encouraged by the ſucceſs of "Orfeo," produced "Alceſte," a ſecond opera, on the reformed plan, at Vienna, which received even more applauſe than the firſt. In 1771, the ſame poet and muſician brought a third opera, "Paride ed Helena," on the ſtage at Vienna, written and compoſed in the ſame new, or rather old, French ſtyle, with better muſic, in which Millico was the principal ſinger, and which afforded the audience ſuch pleaſure as ſeemed to have impreſſed the lovers of muſic in the imperial capital with a partiality for that ſpecies of dramatic muſic, which was not likely to be ſoon obliterated.

In 1772, Gluck ſet to muſic an opera taken from Racine's "Iphigenie," in which he ſo far accommodated himſelf to the national taſte and ſtyle of France, as frequently to imitate and adopt them. And as this opera was intended for Paris, his friends feared for its ſucceſs, as there was frequently *melody*, and always *meaſure*, in his muſic, though ſet to *French words*, and for a *ſerious French* opera.

But the year 1774 was rendered a remarkable era in the annals of French muſic, by the arrival of the chevalier Gluck at Paris, whoſe operas, by his conforming to the genius of the French language, and flattering the ancient national taſte, were received with acclamation. He began his career in this capital by his celebrated opera of "Orphée," of which the reputation was already eſtabliſhed; and this was followed by "Iphigenie," taken from one of Racine's beſt tragedies, which had all the ſucceſs that may be imagined from the force of his genius applied to a favourite drama, ſet in the ſtyle of their favourite compoſers, Lulli and Rameau.

In his opera of "Cythere Aſſiegée," 1775, where more delicacy and tenderneſs, than force, were required in the compoſition, he was not ſo ſucceſsful. Nor was his "Alceſte," the year following, received with the ſame rapture as at Vienna. Indeed his "Armide," in 1777, did not quite fulfil the ideas of grace, tenderneſs, and pathos, which ſome of the ſcenes required, and auditors accuſtomed to Italian muſic expected: however, his operas were excellent preparations for a better ſtyle of compoſition than the French had been uſed to; as the recitative was more rapid and the airs more marked, than in Lulli and Rameau: there were likewiſe more energy, fire, and variety of movement, in his airs in general, and infinitely more force and effect in his expreſſion of grief, fear, remorſe, vengeance, and all the violent paſſions.

Gluck's muſic is ſo truly dramatic, that the airs and ſcenes, which have the greateſt effect on the ſtage, are cold, or rude, in a concert. The ſituation, context, and intereſt, gradually excited in the audience, give them their force and energy.

Indeed, he ſeems ſo much the national muſician of France, that ſince the beſt days of Rameau, no dramatic compoſer has excited ſo much enthuſiaſm, or had his pieces ſo frequently performed. It has been ſaid in the "Journal de Paris," that each of his pieces had ſupported two or three hundred repreſentations. The French, who feel very enthuſiaſtically whatever muſic they like, heard with great rapture the operas of Gluck, which even the enemies of his *genre* allowed to have great merit of a certain kind; but though there is much real genius and intrinſic worth in the dramatic compoſitions of this maſter, the congeniality of his ſtyle with that of their old national favourites, Lulli and Rameau, was no ſmall merit with the friends of that muſic. The almoſt univerſal cry at Paris was now, that he had recovered the dramatic muſic of the ancient Greeks; that there was no other worth hearing; that he was the only muſician in Europe who knew how to expreſs the paſſions; theſe and other encomiums preparatory to his apotheoſis, were uttered and publiſhed in the journals and newſpapers of Paris, accompanied with conſtant and contemptuous cenſures of Italian muſic, when Piccini arrived. This admirable compoſer, the delight and pride of Naples, as Gluck of Vienna, had no ſooner erected his ſtandard in France, than all the friends of Italian muſic, of Rouſſeau's doctrines, and of the plan, if not the language, of Metaſtaſio's dramas, enliſted in his ſervice. A furious war broke out, all Paris was on the *qui vive?* No door was opened to a viſitor, without this queſtion being aſked previous to his admiſſion: "Monſieur! eſtes vous Picciniſte ou Gluckiſte?" Theſe diſputes, and thoſe of muſical critics, and rival artiſts throughout the kingdom, ſeem to us to have ſoured and diminiſhed the pleaſure ariſing from muſic in proportion as the art has advanced to perfection. When every phraſe or paſſage in a muſical compoſition is to be analyſed and diſſected during performance, all delight and enthuſiaſm vaniſh, and the whole becomes a piece of cold mechaniſm. It is certainly neceſſary for profeſſors to ſtudy cauſe and effect, and to make themſelves well acquainted with the fundamental rules of their art; but we would adviſe true lovers of muſic to *liſten* more than talk, and give way to their feelings, nor loſe the pleaſure which melody, harmony, and expreſſion ought to give, in idle enquiries into the nature and accuracy of their auricular ſenſation.

The chevalier Gluck, after returning to Vienna from Paris, and being rendered incapable of writing by a paralytic ſtroke in 1784, only lingered in a debilitated ſtate till the autumn of 1787, when he died at the age of ſeventy-three.

Gluck had great merit as a bold, daring, nervous compoſer; and as ſuch, in his French operas, he was unrivalled. But he was not ſo univerſal as to be excluſively admired and praiſed at the expence of all other compoſers ancient and modern. His ſtyle was peculiarly convenient to France, where there were no good ſingers, and where no good ſinging was expected or underſtood by the public in general; and where the poetry was ſet up againſt muſic, without allowing equality, or even an opportunity of manifeſting her moſt captivating vocal powers.

It is, however, allowed by an excluſive admirer of Gluck, in the Encycl. Meth., that "the Italians have the glory of having furniſhed examples of almoſt every kind of beauty of which muſic is ſuſceptible, and of having diſſeminated their taſte in every part of Europe;" but adds, that "France will owe to the celebrated Gluck the having firſt conceived the ſyſtem of a muſic truly dramatic, and our theatre will furniſh true models of it to other nations, and to poſterity. Let us haſten to ſteal from the Italians and the Germans the glory of laying the true foundation of a muſical ſyſtem and of transforming the moſt amiable and touching of arts, into a ſcience as intereſting as it is fertile."

Gluck, in a moment of *franchiſe*, over a bottle, ſaid "the French are a very good ſort of people, who love muſic, and want *ſongs* in their operas; but they have no ſingers." And Sacchini, being aſked how his operas were executed at Paris, ſaid, "God forbid I ſhould ever go to hear them performed!" And theſe are the people who are to furniſh models of dramatic muſic to Italy, and to all the reſt of Europe!

GLUCKSBURG, in *Geography*, a town of Denmark, with a fortreſs, in the duchy of Sleſwick; nine miles E. of Flenſburg.

GLUCKSTADT, a ſea-port town of Germany, in the duchy of Holſtein, belonging to Denmark, ſituated on the Elbe. This town is regular and well-built, and its market place commands the chief ſtreets. Several canals run through it, and the principal one croſſes near the market place, and is here connected with another, which divides the town into two nearly equal parts. On the land ſide it may be laid under water. Gluckſtadt is the ſeat of the king's regency, and of the offices and courts connected with it. Here is alſo a grammar-ſchool. The Calviniſts are permitted to have a church, the Roman Catholics a chapel, and the Jews a ſynagogue. In 1738 a commercial college was inſtituted here by king Chriſtian VI., as it was a place of ſome trade; and in 1750, king Frederic V. eſtabliſhed an office for keeping the harbour, adjoining to which is a baſin for the reception of veſſels, in good condition. Gluckſtadt was built in 1620 by permiſſion of Chriſtian IV. in a waſte called the Wilderneſs, and in the patent granted to it, he ordered that it ſhould be called Gluckſtadt, or the Fortunate Town; he alſo conferred upon it many cuſtoms, rights and privileges, ſuch as were enjoyed by the town of Wilſter; and it was ſoon after inveſted with the Lubeck and Hamburgh rights. It is diſtant 28 miles N.W. from Hamburgh. N. lat. 53° 51'. E. long. 9° 20'.

GLUE, GLUTEN, a viſcid, tenacious matter, ſerving as a cement to bind or connect divers things together.

There are divers kinds of glues made uſe of in the divers arts; as the common glue, glove glue, parchment glue: but the two laſt are more properly called *ſize*.

The common or ſtrong glue is a commodity uſed by numerous kinds of artificers; as joiners, cabinet-makers, caſe-makers, hatters, book-binders, &c. and the conſumption thereof is very conſiderable. The beſt is that made in England, in ſquare pieces of a ruddy brown colour: Flanders glue, which is whitiſh and tranſparent, is held the next after the Engliſh. The moſt ordinary glue of France is black and opaque.

Glue is made of the ſkins of all kinds of beaſts; as oxen, cows, calves, ſheep, &c. The older the beaſt is, the better is the glue that is made of its hide. Indeed, it is rare they uſe whole ſkins for this purpoſe; thoſe being capable of being applied to better purpoſe: but they make uſe of the ſhavings, parings, or ſcraps of the hides, and alſo horns; and ſometimes they make it of the feet, ſinews, nerves, &c. of beaſts; and alſo of the pelts obtained from furriers.

That made of whole ſkins is the beſt, and that of ſinews, &c. the worſt: and hence, chiefly, ariſes the difference of glues, and the advantage of Engliſh and Flemiſh glues.

GLUE, *method of making*.—Mr. Clennell, in the Monthly Magazine for 1802, gives the following ſtatement of the general mode of its manufacture. The materials above enumerated are "firſt digeſted in lime-water, to cleanſe them from greaſe or dirt; they are then ſteeped in clean water with frequent ſtirring, and afterwards laid in a heap and the water preſſed out. They are then boiled in a large braſs cauldron with clean water, ſcumming off the dirt as it riſes, and it is further cleanſed by putting in, after the whole is diſſolved, a little melted alum or lime finely powdered. The ſcumming is continued for ſome time, after which the maſs is ſtrained through baſkets, and ſuffered to ſettle, that the remaining impurities may ſubſide. It is then poured gradually into the kettle again, and further evaporated by boiling and ſcumming, till it becomes of a clear dark browniſh colour. When it is thought to be ſtrong enough, it is poured into frames or moulds about ſix feet long, one broad, and two deep, where it gradually hardens as it cools, and is cut out when cold by a ſpade into ſquare cakes. Each of theſe is placed in a ſort of wooden box open in three diviſions to the back; in this the glue, while yet ſoft, is cut into three ſlices, by an inſtrument like a bow, with a braſs wire for its ſtring. The ſlices are then taken out into the open air, and dried on a kind of coarſe net-work, faſtened in moveable ſheds four feet ſquare, which are placed in rows in the glue maker's field. When perfectly dry and hard it is fit for ſale. That is thought to be the beſt glue which ſwells conſiderably without melting by three or four days' immerſion in cold water, and recovers its former dimenſions and properties by drying. Glue that has got froſt, or that looks thick and black, ſhould be melted over again. To know good from bad glue, the purchaſer ſhould hold it between his eye and the light, and if it appears of a ſtrong dark colour, and free from cloudy and black ſpots, the article is good." When glue is uſed by the carpenters, they break it and ſoak it for about 24 hours in cold water; and then melt the ſoaked pieces, cauſing it to ſimmer for a quarter of an hour over a ſlow fire and frequently ſtirring it. When cooled it becomes a firm gelly, which may be cut by any inſtrument. It is merely warmed for uſe, and in this ſtate ſpread over the ſurface of the wood with a ſtiff bruſh. In an interval from

One to three days the pieces of wood will be ſo perfectly cemented, that boards, thus cohering, will as readily break in any part as ſeparate at the junction. Glued boards will not ſet in a freezing temperature; the ſtiffening being occaſioned by the evaporation of the ſuperfluous matter of the glue, which is prevented by a conſiderable degree of cold.

Glue, *Bees*. See Wax.

Glue, *Fiſh*, is a ſort of glue made of the nervous and mucilaginous parts of a large fiſh, found chiefly in the Ruſſian ſeas.

Theſe parts, being boiled, bear a near reſemblance to that viſcid matter found on the ſkins of cod-fiſh. When boiled to the conſiſtence of a jelly, they ſpread it on a leaf of paper, and form it into cakes; in which ſtate it is ſent to us.

Fiſh-glue is of conſiderable uſe in medicine, and divers others arts; where it is better known under the name of iſinglaſs and ichthyocolla. See Isinglass.

A ſtrong and fine glue may be prepared with iſinglaſs and ſpirit of wine thus: ſteep the iſinglaſs for twenty-four hours in ſpirit of wine or common brandy. When the menſtruum has opened and mollified the iſinglaſs, they muſt be gently boiled together, and kept ſtirring till they appear well mixed, and till a drop thereof, ſuffered to cool, preſently turns to a ſtrong jelly. Then ſtrain it, while hot, through a clean linen cloth, into a veſſel to be kept cloſe ſtopped. A gentle heat ſuffices to diſſolve this glue into a tranſparent and almoſt colourleſs fluid, but very ſtrong; ſo that pieces of wood, glued together with it, will ſeparate elſewhere than in the parts joined. Boyle's Works abridg. vol. i. p. 130.

A ſtrong compound glue may be made by infuſing a mixture of common glue, in ſmall pieces, with iſinglaſs glue, in as much ſpirit of wine as will cover them, for about twenty-four hours: then melt the whole together, and add as much powdered chalk as will make it an opaque white.

A ſtrong glue, that will reſiſt moiſture, may be obtained by diſſolving gum ſandarac and maſtic, of each two ounces, in a pint of ſpirit of wine, and adding about an ounce of clear turpentine: then take equal parts of iſinglaſs and parchment glue, and having pounded them into ſmall pieces, pour the ſolution of the gums upon them, and melt the mixture in a covered veſſel, with a heat leſs than that of boiling water: then ſtrain the glue through a coarſe linen cloth, and putting it again over the fire, add about an ounce of powdered glaſs.

Or, a ſtrong glue, that will reſiſt water, may be made by adding half a pound of common iſinglaſs glue to two quarts of ſkimmed milk, and evaporating the mixture to a due conſiſtence.

A glue, that will hold againſt fire and water, may be made by mixing a handful of quick-lime with four ounces of linſeed oil, boiling them to a good thickneſs, and ſpreading the mixture on tin plates in the ſhade: it will thus become exceeding hard, but will eaſily be diſſolved over a fire, and be fit for uſe. See Cæment.

GLUMA, a *Huſk*, in *Botany*, is the peculiar calyx of graſſes and graſs-like plants, and indeed their corolla, at leaſt what is ſo termed by Linnæus, is of the ſame chaffy nature. Huſks or Glumes are uſually compreſſed, embracing each other at the baſe; more rarely they are depreſſed, flattened vertically, as in Quaking-graſs or *Briza*. To the huſk belongs the *ariſta* or awn, (ſee Arista,) which is a briſtle-ſhaped appendage, uſually ſpiral, and poſſeſſing the properties of an hygrometer. It originates from the midrib or keel of the huſk, and is either terminal or dorſal, being in the latter caſe placed ſometimes very far down the back of the huſk, as in many ſpecies of *Avena*, and in theſe inſtances it belongs to the glumes that conſtitute the corolla, not the calyx. The *ariſta*, though ſo remarkable, is by no means always conſtant in the ſame ſpecies, though nearly invariably ſo in the flowers of the ſame individual plant.

Huſks are moſtly furniſhed with one central longitudinal rib, though the inner *glumæ* of the corolla in graſſes have two nearly marginal ones. They have in moſt inſtances, beſides the central rib, a greater or leſs number of lateral ones, all likewiſe longitudinal, of great uſe in diſtinguiſhing ſpecies of *Poa* and other difficult genera. Their margin is commonly thin and more or leſs membranous or ſcarioſe. Some *glumæ* always remain ſeparate and diſtinct from the ſeed which they commonly enfold; others are cloſely incorporated with that part as it ripens, of which a curious example may be ſeen in *Briza*.

Some ſorts of viviparous graſſes exemplify the transformation of glumes into leaves in a remarkable manner, the awn remaining at the ſummit being perhaps the only indication of their original nature. See *Aira lævigata*, *Engl. Bot. t.* 2102. The ſame metamorphoſis of a petal into a leaf is indeed not rarely ſeen in a Tulip and other cultivated flowers. We have a wild ſpecimen of a ſimilar change in the *Anemone alpina*, part of whoſe leafy involucrum is become a perfect petal.

Glumes are, we believe, invariably permanent, never deciduous, till the ſeed ripens, when thoſe of the corolla fall off along with the ſeed, ſerving the purpoſe of a *pericarpium*.

GLUMACEOUS Flowers, a term applied by ſome botaniſts to the flowers of the natural order of graſſes, expreſſive of their chaffy nature.

GLUMMEN, in *Geography*, a town of Pruſſia, in the province of Natangen; 24 miles S. of Konigſberg.

GLURANTZ, or Glurs, a town of the county of Tyrol, ſituated on the river Adige, built in 1362, and ſurrounded with walls in 1530. It was taken by the French in 1799; 36 miles W. of Brixen. N. lat. 46° 38'. E. long. 10 26'.

GLUS, in *Surgery*, a ſpecies of dyſury, attended with a copious quantity of mucus in the bladder. Hence, the malady has been named *dyſuria mucoſa*.

GLUT, among *Falconers*, the ſlimy ſubſtance that lies in a hawk's paunch.

Glut, in *Rural Economy*, a term ſometimes provincially applied to a large wooden wedge.

GLUTA, in *Botany*, ſo called by Linnæus, from the Latin word *glutus*, thruſt cloſe together, in alluſion to the cloſe application of the claws of the petals to the ſtalk which elevates the organs of fructification. Profeſſor Martyn ſeems not to have been aware of this derivation. We are led to it by the repeated indication of the circumſtance in Linnæus, and his uſe of the word *adglutinata*, even in the generic character, as well as in his ſubſequent obſervations. Linn. Mant. 2. 160. Syſt. Veg. Ed. 14. 821. Schreb. 146. Willd. Sp. Pl. v. 1. 1120. Mart. Mill. Dict. v. 2. Juſſ. 427. Claſs and order, *Pentandria Monogynia*. (Linnæus refers it to *Gynandria Pentandria*.) Nat. Ord. *Capparides*, Juſſ.?

Gen. Ch. *Cal.* Perianth inferior, of one leaf, membranous, bell-ſhaped, obtuſe at the baſe, cloven half way down into two lobes, deciduous. *Cor.* Petals five, equal, lanceolate, bluntiſh, ſomewhat oblique, four times the length of the calyx; their upper part ſpreading horizontally; their claws cohering round the ſtalk of the germen, and attached to it. *Stam.* Filaments five, briſtle-ſhaped, rather ſhorter than the petals, inſerted into the ſummit of the ſtalk of the germen; anthers verſatile, rather oblong. *Piſt.* Germen obovate, ſtanding on a cylindrical ſtalk, which is rather longer than the calyx; ſtyle thread-ſhaped, equal to the filaments; ſtigma ſimple, obtuſe. *Peric.* and *Seeds* unknown.

Eſſ. Ch. Calyx bell-ſhaped, cloven, deciduous. Petals five; their claws cohering round the ſtalk of the germen. Stamens inſerted into the top of that ſtalk, below the germen.

1. G. *Benghas.* Linn. Mant. 2. 293. Native of Java, where it is called *Benghas*, and, if we miſtake not, in the Malay language *Dodec.* This plant is unknown to all botaniſts except Linnæus, by whoſe herbarium alone it can be determined. His remarks have led the ſtudents of natural orders wide of the truth concerning it, for nothing can be more unlike *Paſſiflora.* To *Sterculia* it has ſome reſemblance, and we have been much inclined to refer it to Juſſieu's *Malvaceæ*, eſpecially from its likeneſs in ſome reſpects to the *Aſſonia* of that author and of Cavanilles; but on examination this likeneſs proves fallacious. The moſt probable place for it is amongſt or near the *Capparides*, but the fruit being unknown, leaves this matter in great doubt. After all, it may be thought to belong to ſome new order, which the ſtudents of natural arrangement are but too prone to make on every emergency, and the French in particular ſeem to think they ſhew their ſkill by their refinements on this head; whereas it is but an eaſier fault, though a more fatal one, than that of making too many genera, and ought to be watched with tenfold care.

The *Gluta Benghas* appears to be a *ſhrub* or *tree*, with ſlightly pubeſcent branches and buds. *Leaves* ſcattered, moſt numerous about the ends of the branches, from three to ten inches long, elliptic-lanceolate, bluntiſh, entire, tapering down at the baſe into a ſhort footſtalk; they are ſmooth on both ſides, furniſhed with one rib and many tranſverſe veins connected by innumerable reticulations. *Stipulas* none. *Flowers* nearly the ſize of *Clematis Flammula*, or, as Linnæus ſays, of a cabbage bloſſom, in a corymboſe panicle; whether terminal or axillary cannot be determined from the ſpecimen, though he aſſerts the former. There is ſome appearance of a glandular depreſſion at the back of the footſtalk where it joins the leaf. S.

GLUTEA, Arteria, in *Anatomy*, a large artery diſtributed chiefly among the glutei muſcles. See Artery.

GLUTEN, Animal, in *Chemiſtry.* See *Animal* Fibre and Blood.

Gluten, *Vegetable*, a ſubſtance reſembling the former, and found in ſeveral vegetables. (See *Vegetable* Fibre.) Beccari firſt found that wheat-flower contained gluten in conſiderable quantity, and from this it is obtained by the following proceſs. (Aikin's Dict.) "Moiſten any quantity of wheat-flour with a little water, and knead it with the hand into a tough ductile paſte, then let a very ſlender ſtream of water keep dropping on the paſte, while it is inceſſantly worked about with the hands, and the water will run off white and turbid, owing to the fecula or ſtarch which it carries off. The paſte in the mean time gradually becomes more of a grey and almoſt ſemi-tranſparent appearance; and when the water runs off quite clear, nothing is left in the hands but pure gluten. No other precaution is required in this preparation but that of not drenching the flour at firſt with water, but only uſing a very ſmall quantity with much kneading, that the gluten may not be carried off along with the ſtarch. Good wheat-flour will yield in this way about a fourth of its weight of gluten, and no other flour but that of wheat will yield it, except in a very ſmall proportion, and hence probably the peculiar property of wheat-flour to make bread without any other addition than a ferment." See Bread.

Gluten is contained in ſmall quantity in ſeveral vegetable juices and other parts, and may be ſeparated from them. Bird-lime is ſuppoſed to be chiefly gluten, and the green fecula of plants abounds with it. See Bird-lime and Fecula.

GLUTEUS, in *Anatomy*, a name given to three large muſcles, concerned in the motions of the pelvis and thigh, and diſtinguiſhed from each other by the epithets magnus, medius, and minor. They occupy the outer and poſterior part of the pelvis, from which they ariſe, and form the large fleſhy prominences named the buttocks.

The *gluteus magnus*, or maximus, le grand feſſier, ilii-ſacro-femoral, is a very broad, thick, and bulky muſcle, compoſed of large faſciculi looſely connected together, and ſeparated to a conſiderable depth by adipoſe and cellular ſubſtance, of an irregularly quadrilateral figure, and ſituated obliquely at the outer and back part of the hip. The rounded ſwelling, which forms the outline of the buttock at its back part, and the projection of which hides the termination of the large inteſtine, is formed entirely by this muſcle. Its external ſurface has the ſame degree of convexity as that of the buttock; the internal, which covers the tuberoſity of the iſchium, and the great trochanter, is proportionally concave. It ariſes, 1ſt. By ſhort aponeurotic fibres, from about one inch of the poſterior extremity of the criſta ilii, where the bone extends beyond the ſacrum, and from the neighbouring part of the immediately ſubjacent notch. At this origin an aponeuroſis may be obſerved, continuous with that of the thigh, and of the vertebral muſcles. 2dly. From the ligament connecting the poſterior end of the iliac criſta, to the back of the ſacrum; and here it is continuous with the tendinous origin of the latiſſimus dorſi, longiſſimus dorſi, and ſacro-lumbalis. 3dly. From the external margin of the ſacrum, near its laſt foramen, from the tubercle at the ſide of the termination of the canal containing the medulla ſpinalis, and from the articulation between the ſacrum and coccyx. 4thly. From the poſterior ſurface of the coccyx. 5thly. From the ſurface of the great ſacro-ſciatic ligament. From theſe points the fibres all proceed obliquely downwards and outwards, nearly parallel to each other; the muſcle is at firſt rather thinner and narrower, and grows broader and thicker as it proceeds. Its upper margin is cloſely attached to that part of the femoral faſcia which covers the gluteus medius. The ſuperior fibres, having turned over the great trochanter, join the upper part of the common tendon. The latter is moſt intimately connected to the faſcia lata, ſo that, on the firſt inſpection, the gluteus magnus appears to be inſerted into this faſcia, throughout the whole line of its front edge: we cannot, however, eaſily diſtinguiſh theſe parts by cutting through the muſcle, and turning it aſide. The common tendon receives the muſcular fibres from above the trochanter, to below the quadratus femoris, where it begins to be attached to the bone. It is very firmly attached to the rough line, which commences at the root of the trochanter, and joins the linea aſpera, occupying by its inſertion a ſpace of about three inches; it is ſituated here between the vaſtus externus and adductor magnus, to the former of which it is connected by tendinous and muſcular fibres.

The exterior convex ſurface of this muſcle is covered for a ſmall ſpace towards its upper part by a thin plate of the faſcia lata, and is every where elſe immediately ſubjacent to the integuments. The inner ſurface covers the os innominatum, the ſacrum and coccyx, the origin of the vertebral muſcles, the gluteus medius, the pyramidales, the gemini, the obturator internus, the quadratus femoris, the tuberoſity of the iſchium, the origins of the ſemitendinoſus and biceps, the adductor magnus, the ſciatic nerve, and the great trochanter. A large ſynovial membrane, placed between this muſcle and the laſt-named eminence, favours their reciprocal motions. The cavity does not in general contain much fluid; and it ſometimes exhibits internal folds.

The *gluteus medius*, le moyen feſſier, ilio-trochanterien, is a thick and broad muſcle, flattened and triangular, partly covered by the preceding, but placed more at the ſide of the pelvis. It ariſes by very ſhort aponeurotic fibres from the external ſurface of the os innominatum, immediately under the criſta ilii, running forwards to the front as far as the anterior ſuperior ſpine, and backwards to the ſacro-ſciatic notch: downwards it is bounded by the curved line, which marks the circumference of the gluteus minimus. Another origin of this muſcle is from the faſcia lata, where that aponeuroſis is fixed to the criſta ilii, and where it ſeparates this muſcle from the tenſor vaginæ. From this double origin the fibres all take their courſe downwards, the anterior or ſhorteſt being at the ſame time directed obliquely backwards; the middle, which are longer, paſſing perpendicularly, and the poſterior or longeſt, coming obliquely forwards. In this way they all converge to meet in a broad aponeuroſis in the radiate fibres, beginning in the ſubſtance of the muſcle, higher behind than before, and deſcending, as it receives the muſcular fibres ſucceſſively, to the great trochanter, to be fixed to the upper and anterior part of that eminence. Many of the anterior fibres are mixed with thoſe of the gluteus minor; ſo that the two cannot be completely ſeparated without dividing ſome of the muſcular ſubſtance.

Its external ſurface is covered behind by the gluteus magnus, in front by the faſcia lata. The inner ſurface covers the gluteus minor, the gluteal artery, and the ſurface of the bone. Its front edge is in contact with the tenſor vaginæ; the poſterior with the pyramidalis.

Gluteus minor, or minimus, le petit feſſier, ilio-iſchii-trochanterien. This is the ſmalleſt of the three glutei, and covers the os innominatum by its whole inner ſurface, being equally covered on the outſide by the preceding muſcle. It is thick and flattened, and has a triangular figure. It ariſes from the ſurface of the os innominatum by very ſhort aponeurotic fibres; beginning at the anterior ſuperior ſpine, and following a curved line, which extends from the latter proceſs to the ſacro-ſciatic notch. From this line, of which the convexity is turned upwards, it covers the bone as far as the edge of the acetabulum. The muſcular fibres all deſcend in a converging manner; the middle taking a perpendicular courſe, while the anterior are directed backwards, and the poſterior forwards. They are all implanted in a broad radiated aponeuroſis, which lies on the external ſurface of the muſcle, except towards the front, where it is covered by a few fibres of the preceding muſcle. This aponeuroſis, as it deſcends, forms a ſtrong tendon implanted immediately within the former, in the upper and anterior portion of the great trochanter. It has ſome connection to the capſular ligament of the hip; and a ſmall ſynovial membrane is interpoſed between it and the trochanter. It is covered by the gluteus medius, and very ſlightly by the pyramidalis: it lies on the bone, on the capſular ligament of the hip, and the origin of the rectus cruris.

Motions produced by the glutei.—The muſcles, which we have juſt deſcribed, move the thigh and pelvis reciprocally on each other. Their action on the pelvis may be obſerved both in ſtanding and walking. When we ſupport the trunk in the erect attitude on both feet, the glutei magni fix the pelvis firmly behind, and counteract that tendency which the body naturally has to fall forwards. Hence the bulk and power of theſe very muſcles in the human ſubject afford a clear proof that man was deſigned for the attitude on two feet; this gives to the human frame the buttocks, which are ſeen in no other animal, becauſe man is the only biped among the mammalia. In the caſe now under conſideration the glutei magni are aſſiſted by the ſemi-tendinoſi, ſemi-membranoſi and bicipites; and antagonized by the pſoæ and iliaci, which poſſeſs a force much inferior to that which oppoſes them behind, becauſe they are aided by the weight of the trunk. When the pelvis has been bent forwards, the gluteus magnus will reſtore it; and if the circumſtances admitted of this part being carried backwards, the ſame muſcle would produce that motion. The other two glutei are not eſſentially concerned in the attitude of ſtanding on both feet; but they are the principal agents in ſupporting and balancing the trunk on one foot, by inclining the pelvis over the head of that thigh bone on which the body reſts, ſo that the centre of gravity of the trunk may be in a line drawn through that lower extremity. In this caſe their exertion counteracts the tendency of the trunk to fall on that ſide which is not ſupported. Theſe muſcles are further employed in the ſame kind of way in progreſſion: the gluteus magnus balances the pelvis while one leg is carried before the other, and brought to the ground; and the two others ſupport the trunk laterally, while the limb of the oppoſite ſide is in the air. In the attitude on one leg, the gluteus magnus can rotate the pelvis on the thigh-bone of its own ſide, ſo as to turn the ſymphyſis pubis towards the oppoſite ſide. When the glutei move the thigh on the pelvis, the magnus reſtores the bone to its former poſition, where it had been previouſly bent: and, if the pelvis be carried forwards, it may move the former ſtill farther in the direction of extenſion; the medius and ſemi-medius move the thigh away from the oppoſite limb. The g. magnus has the effect alſo of rotating the thigh outwards; while the anterior fibres of the two ſmaller muſcles will rotate it inwards. The former is a tenſor of the faſcia lata.

GLUTTON, in *Zoology.* See Ursus *Gula.*

GLYCAS, Michael, in *Biography*, a Greek hiſtorian, who is ſuppoſed to have flouriſhed in the 12th or 13th century, though by ſome others he is referred to the 15th. He was a native of Byzantium, but ſpent a great part of his life in the iſland of Sicily. He is principally known by his "Annals," in four parts, containing the hiſtory of the world, from the creation to the birth of Chriſt, and that of the Byzantine emperors down to the death of Alexius Comnenus in 1118, interſperſed with a number of theological, philoſophical, and phyſical diſcuſſions. An edition of the "Annals" in Greek and Latin was given to the public by father Labbe, in 1660. The third part has been publiſhed ſeparately by Meurſius, with a verſion and ſcholia. Several letters of Glycas have been publiſhed in different collections. He was undoubtedly a very learned man, and the correſpondence which he maintained with the literati of his age ſhew that he ſtood in very high reputation. Moreri.

GLYCERIA, in *Botany*, from γλυκερος, *ſweet*, the ſeeds being eaten in Germany, and called Manna-ſeeds, on account of their ſweet taſte. Brown Prod. Nov. Holl. v. 1. 179.—Claſs and order, *Triandria Digynia.* Nat. Ord. *Gramina.* This new genus of graſſes is founded by Mr. Brown on the *Feſtuca fluitans* of Linnæus, *Poa fluitans*, Sm. Fl. Brit. 95, with the following characters.

"*Glume* (Calyx) of two valves, containing many flowers. *Spikelet* cylindrical, awnleſs. *Perianth* (Corolla) beardleſs, its valves of equal length. *Scale* under the germen ſolitary, fleſhy, like a half ſhield. *Stigmas* doubly compound. *Seed* uncomunconnected, oblong, with a furrow at one ſide. *Flowers* ſomewhat panicled."

We cannot but aſſent to the propriety of ſeparating the graſs in queſtion from *Poa* and *Feſtuca*, as far as habit is concerned, but we are very certain that *Poa diſtans*, *maritima*, *procumbens*, and *rigida* of Fl. Brit. and *Cynoſurus durus* of Linnæus cannot fail to go along with it, though we fear the characters given by the ſagacious writer above quoted will not be found to hold good in all, if in any, of theſe. Perhaps the following definition of *Glyceria*, formed on ſimple and obvious Linnæan principles, may be unexceptionable, as embracing them all, and preſerving an analogy with genera already eſtabliſhed.

Calyx of two valves, containing many florets. Spikelet linear. Corolla of two oblong, obtuſe, beardleſs valves. S.

GLYCINE, from γλυκυς, *ſweet*, the particular application of which is not very obvious, having originated merely from the ſweet taſte noticed by Cornuti in the leaves and tuberous roots of G. *Apios*. This indeed is the original, and perhaps the only true *Glycine*, the numerous aſſemblage of ſpecies ranged under this genus, by recent writers, being very anomalous in fructiſication, eſpecially thoſe of New Holland, as will appear by Mr. Brown's definitions when the ſecond part of his valuable work appears.—Linn. Gen. 373. Schreb. 495. Willd. Sp. Pl. v. 3. 1053. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 34. Juſſ. 357. Lamarck Illuſtr. t. 609. Gærtn. t. 154. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, compreſſed, two-lipped; upper lip notched, obtuſe; lower longer, three-cleft, acute, its middle tooth longeſt. *Cor.* papilionaceous. Standard inverſely heart-ſhaped, deflexed at the ſides, gibbous at the back, emarginate at the top, and ſtraight, till driven back by the keel. Wings ſmall, oblong, ovate towards the extremity, bent downwards. Keel linear, falcate, curved upwards, preſſing the ſtandard upward by its obtuſe and dilated extremity. *Stam.* Filaments in two ſets, (one ſimple, the other in nine diviſions,) ſlightly ſeparated at the top, revolute; anthers ſimple. *Piſt.* Germen oblong; ſtyle cylindrical, rolled ſpirally; ſtigma obtuſe. *Peric.* Legume oblong. *Seeds* kidney-ſhaped.

Eſſ. Ch. Calyx two-tipped. Stamens in diſtinct ſets. Keel of the corolla forcing back the ſtandard with its point.

Obſ. *Glycine Apios* and *fruteſcens* have a two-celled legume. G. *monoica* is a ſingular inſtance of a ſeparation of ſexes in flowers of this tribe.

This genus has accumulated from two ſpecies (G. *Apios* and *fruteſcens*) in the *Hortus Cliffortianus*, to eight in the firſt edition of *Species Plantarum*, nine in the ſecond, fifteen in the fourteenth and laſt edition of *Syſtema Vegetabilium*, and finally to forty-four in Willdenow. Theſe now form a very heterogeneous aſſemblage, and the New Holland ones conſtitute a diſtinct genus, the *Kennedia* of Ventenat, diſtinguiſhed by its ſpontaneouſly reflexed ſtandard, and legume of many cells. The whole requires a thorough reviſal. Some are of opinion that G. *Apios* is generically diſtinct from all the others, and if ſo it would be moſt convenient, though this is one of the original ſpecies, to give it the generic name of *Apios*, retaining *Glycine* for ſuch more common and more numerous ones as may anſwer to the uſual idea of the genus, an eſſential character being ſelected to combine them together.

Glycine, in *Gardening*, contains plants of the ſhrubby climbing kind; of which the ſpecies cultivated are the ſhrubby glycine, or Carolina kidney-bean tree (G. fruteſcens); the two-ſpotted glycine (G. bimaculata); the reddiſh-flowered glycine (G. rubicunda); and the ſcarlet glycine (G. coccinea.)

Method of Culture.—In the firſt it may be effected by laying down the young branches in the early autumnal ſeaſon. When well-rooted in the following autumn, they may be taken off and planted where they are to remain, or in nurſery-rows, being watered when the weather is hot, and the roots protected in the winter by ſome ſort of ſtrawy material. They are found to ſucceed beſt in dry, warm, light ſorts of ground.

And the other kinds may be raiſed by ſowing the ſeeds when they can be obtained from abroad, or produced here in pots of light earth, in the early ſpring, being afterwards removed into other pots, and placed in the green-houſe, or Cape ſtove. It has been ſuppoſed by Mr. Curtis, that the two laſt may ſucceed in the open air, when planted out in warm ſheltered ſituations, and protected during the winter ſeaſon by ſome convenient matting or other means.

All the ſorts are ornamental in their flowery climbing growth; the firſt in the open ground, and the latter in the green-houſe and ſtove collections.

Glycine, *Glucine*, Fr. in *Chemiſtry*. This earth was firſt diſcovered by M. Vauquelin in 1798. He detected it in the analyſis of the beryl, undertaken at the deſire of Haüy, who wiſhed to have it aſcertained by a ſtrict chemical inquiry, whether the beryl and emerald were as ſimilar in their compoſition as in the form of their cryſtallizations. The reſults of this inquiry were conformable to the expectations which gave riſe to it, and the exiſtence of a new earth in the beryl and emerald was confirmed by the experiments of Klaproth. Vauquelin, in the memoir in which he announced his diſcovery, called the new ſubſtance merely the earth of the beryl: afterwards, with his aſſociates, Guyton, Fourcroy, and Chaptal, he determined on the name *glucine*, derived from the Greek γλυκος, *ſweet*, becauſe all the ſoluble ſalts of this earth have the property of producing a certain ſweet aſtringent taſte. When the name was ſelected, the character on which it was founded was peculiar; but though it ceaſed to be ſo on the diſcovery of yttria, yet as the name conveys no erroneous ideas of the body, to which it is applied, there is no impropriety in adhering to it: beſides, the taſte ſtill ſerves as a phyſical characteriſtic; for, according to Vauquelin, the ſweetneſs of the ſalts of glycine has a ſenſible difference from that of the ſalts of yttria, particularly of the ſulphat.

Glycine, in its pure ſtate, has not yet been diſcovered in nature: indeed, its occurrence in compound minerals is exceedingly rare, for it has only been found in the beryl, or ultramarine, the emerald and the gadolinite; and it enters but ſparingly into the compoſition of theſe bodies; the beryl, in which it is moſt abundant, containing, according to the analyſis of Vauquelin and Roſe, no more than 14 *per cent.* From the analogy which exiſts between glycine and alumine, the former is very liable to be taken for the latter by chemiſts who do not pay particular attention to accuracy in their analytical inquiries. The firſt analyſes of the emerald made by Klaproth and Vauquelin afford an inſtance of this kind: and M. Bindheim committed a ſimilar error in his analyſis of the beryl.

To obtain glycine in a ſtate of chemical purity, finely powdered beryl is to be fuſed with three times its weight of cauſtic potaſh in a ſilver or platina crucible; the crucible is to be expoſed for two hours to a ſtrong red heat, and the mixture in fuſion is to be frequently ſtirred with an iron rod, in order to keep the earth as much as poſſible ſuſpended and expoſed by an extent of ſurface to the action of the alkali. If the treatment deſcribed is properly conducted, the fuſed maſs, when ſoftened with water, will be entirely diſſolved by muriatic acid, aſſiſted by a ſlight digeſting heat: the muriatic ſolution thus procured muſt be evaporated to dryneſs. A large quantity of water will diſſolve the ſoluble ſalts, and leave the principal part of the ſilex, which is to be ſeparated and well waſhed on a filter. The filtered ſolution is to be precipitated by carbonat of potaſh. The precipitate, conſiſting principally of alumine and the earth in queſtion, is to be diſſolved in dilute ſulphuric acid, and evaporated to the proper conſiſtence to afford cryſtals of alum. If the precipitate produced by carbonat of potaſh has been well waſhed, it is neceſſary to add a little potaſh to the ſulphuric ſolution. When the ſolution, on a ſecond or third evaporation, and addition of potaſh, ceaſes to yield any more cryſtals of alum, the mother liquor is to be mixed with a ſolution of carbonat of ammonia, greatly exceeding the quantity neceſſary to ſaturate the acid, and to be transferred to a bottle having a ground ſtopple: the mixture is to be well agitated, and carbonat of ammonia is to be added till the precipitate which firſt appeared is re-diſſolved, or no longer diminiſhed by freſh portions of the carbonated alkali. The ſolution of the triple compound of glycine carbonic acid and ammonia is to be filtered in order to ſeparate the ſmall remaining quantity of alumine, and then boiled till the vapour ceaſes to change the colour of turmeric paper, or till it no longer has an ammoniacal ſmell; when all the carbonat of ammonia being driven off, the whole of the glycine will be found precipitated in the form of a white granular powder combined with carbonic acid. This powder is to be waſhed in a filter, till the water ceaſes to afford a precipitate with muriat of barytes and lime-water; it is then to be dried, and heated to redneſs: by this means, the water and carbonic acid, amounting to about half the weight of the whole, will be expelled, and the glycine, if it does not effervеſce with acids, will be left in a perfectly pure ſtate.

Glycine thus procured, is a ſnow-white powder, ſoft and ſomewhat unctuous between the fingers, very adheſive to the tongue, and deſtitute both of ſmell and taſte. Its ſpecific gravity is 2.976. It produces no change in the colour of vegetable blues. Neither oxygen nor nitrogen has any action on it, nor does it ſuffer any change by expoſure to the atmoſphere; as carbonic acid and moiſture do not appear to be abſorbed by it. It forms, with a ſmall quantity of water, a ſlightly ductile paſte, that poſſeſſes much leſs tenacity than that of alumine. Glycine has not yet been fuſed; it neither contracts nor hardens when heated, nor is it altered by expoſure to the moſt intenſe fire. With borax it forms a white tranſparent glaſs, which does not become opaque on cooling. It refuſes to combine directly with ſulphur or phoſphorus, but it appears from Fourcroy that a ſulphuret may be formed by decompoſing the ſulphat of glycine by charcoal. Glycine is ſoluble in a ſaturated ſolution of ſulphuretted hydrogen. A hydro-ſulphuret of this earth, it is likewiſe ſaid, may be obtained by diſſolving the ſulphuret in water. In theſe properties it approaches the alkaline earths, and conſtitutes apparently the link of union between them and the claſs to which it belongs. It is diſſolved by both the fixed alkalies in their liquid ſtate, but in a leſs degree than alumine, and, like alumine, it is not taken up by ammonia. It is diſſolved in a ſolution of carbonat of ammonia, as has already been mentioned. It very readily unites with acids. All its ſoluble ſalts produce, when firſt taſted, the ſenſation of ſweetneſs, which gradually becomes aſtringent.

In relation to its affinity for acids, glycine appears to be intermediate between alumine and magneſia, for it decompoſes only the ſalts of alumine, yttria, and zircon. And the order of its affinities is much the ſame, according to Fourcroy, as that of the other earths, ſulphuric acid holding the firſt place, and nitric, muriatic, phoſphoric, fluoric, boracic, and carbonic following. No experiments have been undertaken yet, to aſcertain what combinations glycine is capable of forming with the earths and metallic oxyds.

Yttria and alumine are the only earths for which glycine is liable to be miſtaken: the properties in which it reſembles them are, rather unfortunately, of a moſt ſtriking kind, but it has a number of other characters which are very diſtinct, and fully demonſtrative of its peculiar nature. Glycine is ſimilar to alumine, in being ſoluble in cauſtic ſolutions of the fixed alkalies, and in ſome of its phyſical qualities; but it differs from alumine in affording with acids ſweet aſtringent ſalts; in not yielding alum with ſulphuric acid and potaſh; in poſſeſſing a greater affinity for acids; in being entirely ſoluble in carbonat of ammonia; and laſtly, in not being precipitated from its ſolutions by oxalat, tartrat, or pruſſiat of potaſh. It is to be diſtinguiſhed from yttria, by its greater ſolubility in carbonat of ammonia, the latter requiring for its ſolution five times as much carbonated alkali as glycine, by its ſalts occaſioning a precipitate, when added to any of the ſuccinats, by the inſolubility of yttria in fixed alkaline ſolutions, and by the precipitate which the ſalts of yttria afford with pruſſiat of pot-aſh.

Glycine was conſidered as a ſimple body till the important diſcoveries of Mr. Davy gave riſe to new analogies; and though the compound nature of this earth is not yet fully demonſtrated, yet there is every reaſon to believe that glycine, like the alkalies and alkaline earths, is a metallic oxyd: and the reſults of the experiments which Mr. Davy made on this body are explained beſt on ſuch a ſuppoſition. This gentleman negatively electrified glycine, ſlightly moiſtened in contact with an amalgam of potaſſium, under naphtha, by a battery of 500 plates. After an hour the amalgam was thrown into water, and an alkaline ſolution was produced, which became cloudy when neutralized by acid, thus indicating the preſence of the earth. Mr. Davy, following the nomenclature which he has adopted in reſpect to the new metals, has propoſed glucium for the name of the metal of glycine, when its exiſtence is no longer doubtful.

Carbonat of glycine, as well as all the other ſalts of this earth, has not yet been diſcovered ready formed in nature. It is procured by precipitating the ſulphat, nitrat, or muriat of glycine, by either of the carbonated fixed alkalies. The precipitate, which is the ſalt ſought after, being well waſhed and dried, appears in the form of ſoft white powder, having a greaſy feel and great lightneſs. Carbonat of glycine is inſoluble in water, and it is unaltered by expoſure to the air. It is decompoſed by all the acids, and by the action of a red heat: moſt probably all the alkaline earths deprive it of carbonic acid in the moiſt way. According to Klaproth it is compoſed of

Glycine	53
Carbonic acid and water	47
	100

Phoſphat of Glycine.—Phoſphat of ſoda, added to a neutral ſolution of nitrat of glycine, throws down this ſalt either in a white pulverulent form, or in a mucilaginous ſtate. It is inſoluble in water, inſipid and uncryſtallizable.

It is not decompoſed by a violent heat, but it fuſes into a white tranſparent glaſs, that does not become opaque on cooling. Phoſphat of glycine is ſoluble in phoſphoric acid. The ſulphuric and nitric acids firſt diſſolve this ſalt, and afterwards decompoſe it. Muriatic acid produces a ſimilar effect, but in a leſs degree. It is likewiſe readily decompoſed by the carbonated alkalies and by all the carbonated earths, except carbonat of magneſia. With the ſulphat, nitrat, and muriat of alumine, it ſuffers decompoſition, a mutual exchange of acids taking place between the two earths.

Sulphat of Glycine.—Glycine, both in its pure and carbonated ſtate, diſſolves very readily in dilute ſulphuric acid. The ſolution by ſpontaneous evaporation affords octahedral cryſtals, compoſed of two oblique four-ſided pyramids joined baſe to baſe, with their edges and ſolid angles truncated. It alſo, but with difficulty, yields when evaporated on a ſand bath ſmall needle-form cryſtals. The ſolution, when evaporated nearly to dryneſs, aſſumes a ſyrupy conſiſtence. Sulphat of glycine, has a remarkable ſweet and aſtringent taſte. It is very ſoluble in water. Heated, it intumeſces, ſuffers the watery fuſion, and becomes pulverulent from the diſſipation of its water. It is completely decompoſed by a ſtrong red heat, the acid being expelled and the earth left in its pure ſtate. It has been already obſerved that ſulphat of glycine is converted, when heated with charcoal, into a ſulphuret: but this ſulphuret, according to Fourcroy, does not become a pyrophorus, like alum thus treated, though ſulphat of potaſh be preſent. A ſolution of nut-galls, added to this ſalt diſſolved in water, produces immediately a white precipitate. Previous to the knowledge of this fact, ſuch a property was conceived to be peculiar to metallic ſalts.

Sulphat of glycine, ſlowly evaporated with a ſmall quantity of ſulphat of potaſh, forms minute cryſtalline grains, which diſſolve with eaſe in ſeven or eight times their weight of cold water. Glycine, added to a ſolution of alum, precipitates the alumine, and moſt probably produces a compound, ſimilar to the preceding one. Sulphat of glycine is decompoſed by all the alkalies and earths, excepting alumine, yttria, zircon, and ſilex.

Nitrat of glycine is procured by ſaturating nitric acid with glycine. The ſolution of this ſalt does not afford cryſtals by evaporation, but produces a ductile and adheſive maſs, which, when further dried, falls into powder. It is very ſoluble in water and deliqueſcent in the air. It attracts moiſture ſo ſtrongly, that it might, if eaſily procured, be advantageouſly employed for abſorbing the hygrometrical water of gaſes. Its taſte is ſaccharine and aſtringent. Tincture of galls dropt into a ſolution of this ſalt produces a yellowiſh brown precipitate. Nitrat of glycine fuſes at a low heat, but if the heat is increaſed, the acid is expelled. It is decompoſed in the moiſt way by ſulphuric acid, and by the ſame alkalies and earths as the ſulphat. The proportions of its component parts are not known; but Vauquelin has obſerved that a given quantity of nitric acid requires rather more glycine than alumine for its complete ſaturation; yet the former earth, though in combination with nitric acid more ſoluble than the latter, decompoſes, with the aſſiſtance of heat, nitrat of alumine, precipitating the alumine, and forming nitrat of glycine.

Muriat of glycine is procured by diſſolving glycine in muriatic acid. It is in ſome reſpects ſimilar to the nitrat, but differs in its ſolution, affording by careful management ſmall cryſtals, the form of which, on account of their ſize, have not yet been determined; and in not being ſubject to deliqueſce on expoſure to the atmoſphere. Its taſte is ſimilar. A ſolution of this ſalt in dilute alcohol is ſaid to be an agreeable ſweet liquid. When diſtilled *per ſe*, the acid flies off, and leaves the earth in a ſtate of purity. It is alſo decompoſed when heated with phoſphoric acid. The ſame effect is produced by ſulphuric and nitric acids, and by the alkalies, and all the earths that decompoſe the nitrat.

Acetat of glycine, which is prepared by diſſolving the earth in acetic acid, has not yet been procured in a cryſtalline form. Its ſolution, when evaporated, acquires a glutinous conſiſtence, and the ſalt becomes brittle as it ſlowly dries.

Succinat of Glycine.—Any of the ſuccinats added to the nitrat, muriat, or ſulphat of glycine, precipitate the ſalt in queſtion. Its properties have not yet been enquired into.

We are indebted for the imperfect knowledge we have of the combinations of glycine, with the ſeveral acids above-mentioned, principally to the celebrated diſcoverer of this earth. Glycine, in no form as yet, has been uſefully employed; yet Vauquelin conceives that the earth itſelf and ſome of its ſalts, when they can be procured with facility, may admit of ſuch an application in chemiſtry, in medicine, and the arts. Its marked attraction for animal and vegetable colouring ſubſtances induced him to think that there was a probability of its being ſerviceable as a mordant; and the peculiar taſte of ſome of its ſalts gave riſe to the hope that theſe combinations might produce ſalutary effects on the animal ſyſtem. If his expectations ſhould be realized, we muſt agree with Vauquelin, that theſe ſalts will be ſome of the moſt agreeable medicines that exiſt. Ann. de Chem. vol. xxvi. 155. xlii. 277. Fourcroy Connaiſſance Chem. vols. ii. iii. Aikin's Chem. Dict. vol. ii. Philoſoph. Tranſ. part. ii. 1808. p. 352.

GLYCONIAN, Glyconius, in the Greek and Latin poetry.

A Glyconian verſe is that conſiſting of two feet and a ſyllable; at leaſt this is Scaliger's opinion: who adds, that the Glyconian verſe was alſo called the Euripidean verſe. See Verse.

Others hold, that the Glyconian verſe conſiſted of three feet, a ſpondee and two dactyls; or rather a ſpondee, choriambus, and an iambus or a pyrrhic: which opinion is the moſt followed.

"Sic te diva potens Cypri," is a Glyconian verſe.

GLYCYRRHIZA, in *Botany*, Liquorice, γλυκυῤῥιζα of Dioſcorides, who deſcribes the plant very faithfully and accurately; but it is remarkable that he ſays the flower is like a hyacinth, which can allude to the colour only, whether his ὑακινθος be the *Delphinium* or *Hyacinthus* of modern botaniſts. The word is compoſed of γλυκυς, *ſweet*, and ῥιζα, *a root*; and the name in apothecaries' Latin, *liquiritia*, as well as the Engliſh one, liquorice, the French *regliſſe*, the Italian *regalizza*, &c. with all their corruptions, originate from it.—Linn. Gen. 380. Schreb. 502. Willd. Sp. Pl. v. 3. 1143. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 56. Juſſ. 359. Tourn. t. 210. Lamarck. Illuſtr. t. 625. Gærtn. t. 148.—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, two-lipped, permanent; upper lip in three deep ſegments, of which the lateral ones are linear, the central one broadeſt and cloven; lower perfectly ſimple, linear. *Cor.* papilionaceous. Standard ovato-lanceolate, ſtraight, longeſt. *Wings* oblong, very like the keel, but rather larger. Keel of two petals, acute, its claw the length of the calyx. *Stam.* Filaments in two ſets, (one ſimple, the other in nine diviſions,) ſtraight; anthers ſimple, roundiſh. *Piſt.* Germen ſhorter than the calyx; ſtyle awl-ſhaped, as long as the ſtamens; ſtigma obtuſe, aſcending. *Peric.* Legume ovate or oblong, compreſſed, acute, of one cell. *Seeds* very few, kidney-ſhaped.

Eſſ. Ch. Calyx with two lips; the upper three-cleft; lower ſimple. Stamens in diſtinct ſets. Legume ovate, compreſſed, of one cell. Seeds one or two.

1. G. *echinata.* Linn. Sp. Pl. 1046. Jacq. Hort. Vind. v. 1. t. 95. (Dulcis radix; Matth. Valgr. v. 2. 16. Camer. Epit. 423.)—“Legumes prickly. Flowers capitate. Stipulas lanceolate. Leaflets ſmooth; the terminal one nearly ſeſſile.”—Native of Italy, as well as of Tartary and the confines of China; alſo abundantly, according to Dr. Sibthorp, on the ſandy ſhores of Crete, Samos, and other Greek iſlands, where it ſtill retains its ancient name unchanged. The long pliant perennial *roots*, deeply deſcending into the ground in a favourable ſoil, are cultivated for their ſweet taſte and pectoral virtues, and are ſufficiently well known. The *ſtems* are two or three feet high, nearly ſimple, leafy, round and ſtriated. *Leaves* of ſeveral pair of equal, elliptical, entire, acute leaflets, the odd one on a little ſtalk only like the reſt, not on an elongation of the main footſtalk. *Stipulas* lanceolate, acute. *Flowers* ſeveral, in axillary, ſolitary, ſtalked heads; their colour a dull purple. *Legumes* clothed, in their upper part eſpecially, with numerous long rigid prickles, reſembling the fruit of *Xanthium ſtrumarium.* Dioſcorides compares them to that of the Plane-tree. The whole herb is deſtitute of pubeſcence, but ſomewhat clammy to the touch.

2. G. *fœtida.* Desfont. Atlant. v. 2. 170. t. 199.—Legumes prickly. Flowers ſpiked. Stipulas lanceolate. Leaflets ſcaly beneath; the terminal one nearly ſeſſile.—Found by Desfontaines on mount Atlas, and in cultivated fields near Mayane in Africa. We have it from Alcaſſar. Whole plant extremely fœtid. *Leaves* much like the laſt in ſize and ſhape, but the *flowers* are pale yellow, in long ſpikes. *Legumes* crowned with the permanent ſtyle, which is longer in this than in the former. The *ſtem*, as well as both ſides of the leaves, is beſprinkled with minute ſcales.

3. G. *glandulifera.* Waldſt. and Kitaib. Hungar. v. 1. 20. t. 21. Willd. Sp. Pl. v. 3. 1144.—Legumes clothed with glandular briſtles. Flowers ſpiked. Stipulas obſolete. Leaflets emarginate, glutinous and downy beneath.—Native of Hungary. *Flowers* violet-coloured.

4. G. *glabra.* Linn. Sp. Pl. 1046. Woodv. Med. Bot. t. 167. (G. vulgaris; Dod. Pempt. 341. Ger. em. 1302.)—Legumes ſmooth. Flowers ſpiked. Stipulas ſcarcely diſcernible. Leaflets blunt; the terminal one on a long ſtalk.—Native of the ſouth of Europe. Moſt commonly cultivated with us. The *leaflets* are large, glutinous beneath. *Flowers* pale purple, in long-ſtalked axillary ſpikes. *Legumes* oblong, ſmooth.—We have a ſpecimen of this ſpecies gathered in Circaſſia, by the celebrated traveller Dr. Clarke of Cambridge.

5. G. *aſperrima.* Linn. Suppl. 330. Pallas. Reis. v. 3. t. G, g. f. 1, 2. (G. hiſpida; ibid. 754.)—Legumes ſmooth, beaded. Flowers ſpiked. Stipulas lanceolate. Leaflets roundiſh, prickly beneath. Stem and footſtalks prickly.—Found by profeſſor Pallas “in ſandy ground between the river Wolga and the Tanais.” *Pallas MSS.* The *root* is extremely ſweet, eſpecially in the ſpring. *Stems* uſually two, rarely three, aſcending, a ſpan high, nearly ſimple, leafy, rough with numerous little rigid prominent prickles, as are the *footſtalks*, and backs of the *leaflets.* The latter are roundiſh or obovate, obtuſe with a little point, ſmooth and veiny above. *Flowers* longiſh, pale violet, with whitiſh wings and keel, in one or two thick ſpikes about the top of each ſtem. The *legumes* are drawn by Pallas above an inch long, recurved, of a necklace-like form, and ſmooth, containing many ſeeds. The *calyx* is oblong, purpliſh, rather hairy. It has the habit of a *Glycyrrhiza*, flowers of an *Aſtragalus*, and fruit apparently of a *Coronilla*; nor does the calyx anſwer to the generic character, being five-cleft.

6. G. *hirſuta.* Linn. Sp. Pl. 1046. (G. orientalis, ſiliquis hirſutiſſimis; Tourn. Cor. 26.)—“Legumes hairy. Leaflets oblong-lanceolate, the terminal one on a long ſtalk. Flowers ſpiked.”—Found by Tournefort in the Levant. *Root* perennial. Of this we have ſeen neither a ſpecimen, figure, nor any further deſcription.

GLYCYRRHIZA, in *Gardening*, furniſhes a plant of the herbaceous perennial kind, the common liquorice (G. glabra).

It is a plant which has the roots running very deep into the ground, and creeping to a conſiderable diſtance, eſpecially where they ſtand long unremoved.

Method of Culture.—A light ſandy ſoil is the moſt adapted to the growth of this ſort of crop, as its goodneſs conſiſts in the length of the roots. The ground in which it is intended to be planted ſhould be well dug and dunged the year before planting, that it may have become perfectly mellow, and the dung well rotted and mixed with the earth, otherwiſe it will be apt to ſtop the roots from running down and being properly ſupported; and immediately before planting it ſhould be well dug again to the depth of three ſpades, and be laid very light and open.

When the land is thus prepared, freſh plants taken from the ſides or heads of the old roots ſhould be provided, care being taken that they have each a good bud or eye, being about ten inches long and perfectly ſound.

The operation of planting them ſhould be performed about the middle of March, which is done in this manner: a line is firſt ſet acroſs the ground, then, with a long dibble made on purpoſe, the ſhoots or cuttings are put in, ſo that the whole plants may be ſet into the ground, with the heads about an inch under the ſurface, in a ſtraight line about a foot aſunder in the rows, and a foot and a half or two feet row from row.

When the whole ſpot of ground has been thus planted, a thin crop of onions may be ſown over the land. Theſe muſt be kept perfectly clean by the hoe, care being taken not to cut off the top ſhoots of the liquorice plants, as it would greatly injure them. All the onions which grow near the heads of the liquorice ſhould alſo be removed. In October, the ſhoots of the liquorice ſhould be removed, and a little very rotten dung ſpread upon the ſurface.

In the following ſpring, about March, the ground ſhould be ſlightly dug between the rows of liquorice, burying the remaining part of the dung, being very careful not to cut the roots.

During the ſummer they muſt be kept quite clean by occaſional hoeing. The ſame operations muſt be annually performed, ſo as to keep the ground and plants in perfect order.

Theſe plants muſt remain three years from the time of planting, when they will be fit to take up for uſe, which ſhould be done when the ſtalks are perfectly decayed; as, when taken up too ſoon, the roots ſhrink greatly, and loſe in weight.

In taking up the roots the ground is trenched over, row after row, to the full depth, and the young ſhoots taken from the old roots cut into ſets for new plantations; which ſhould be made annually, in order to keep a conſtant ſucceſſion of roots fit for being taken up.

The great art in this culture is to have the earth well trenched to a proper depth, to have good ſets, and to keep the ground afterwards quite clean by hoeing and other proper means.

The liquorice is a native of the ſouth of Europe, but it has been cultivated in Britain ever ſince the time of Turner. (See Tourn. Herb. pt. 2. fol. 12. publiſhed in 1562.) The chief places in which it has been long propagated for ſale are, Pontefract, in Yorkſhire; Workſop, in Nottinghamſhire; and Godalming, in Surry; but it is now planted by many gardeners in the vicinity of London, who ſupply the metropolis with the roots.

Glycyrrhiza, in the *Materia Medica*. The root of the common liquorice, boiled ſlightly in a little water, gives out nearly all its ſweetneſs. The decoction, preſſed through a ſtrainer, and inſpiſſated with a gentle heat, till it will no longer ſtick to the fingers, affords a better extract than that brought from abroad, and particularly from Spain, whence our ſhops are chiefly ſupplied with it, and its quantity amounts to near half the weight of the root. The extract that is prepared here, is made by macerating, for four hours, liquorice root ſliced, a pound, in a gallon of boiling water; then boiling down to four pints, ſtraining the hot liquor, and evaporating it to a proper conſiſtence. A purer extract may be made by a repetition of the proceſſes of ſolution and evaporation; and it is kept in the ſhops under the name of "refined liquorice." Rectified ſpirit takes up the ſweet matter of the liquorice equally with water; and as it diſſolves much leſs of the inſipid mucilaginous ſubſtance of the root, the ſpirituous tinctures and extracts are proportionably ſweeter than the watery. This root contains a great quantity of ſaccharine matter, leſs diſpoſed to run into fermentation than that of other vegetables, which is joined with ſome proportion of mucilage, and hence has a viſcid ſweet taſte. From the time of Theophraſtus it has been a received opinion that it very powerfully extinguiſhes thirſt; accordingly it was named ἄδιψον, and the root directed to be chewed in dropſies and other diſorders where great thirſt prevailed. If this fact be true, it is the more remarkable, as ſweet ſubſtances in general have a contrary effect. Accordingly Dr. Cullen obſerves, that the ſweet of liquorice, ſeparated from the root, does not quench thirſt more than other ſweets: and he aſcribes the error reſpecting it to this circumſtance, that if a piece of the root is chewed till the whole of the ſweetneſs is extracted, farther chewing brings out the acrid and bitteriſh matter, which ſtimulates the mouth and fauces, ſo as to produce an excretion of fluid, and thereby takes off the thirſt which the ſweetneſs had produced. Liquorice is in common uſe as a pectoral or emollient in catarrhal defluxions on the breaſt, coughs, hoarſeneſſes, &c. Infuſions or extracts from it afford likewiſe very commodious vehicles for the exhibition of other medicines. Lewis's M.M. Cullen M.M. Woodv. Med. Bot.

GLYN, in *Geography*, a county in the lower diſtrict of Georgia, in the United States, bounded E. by the ocean, N. by Alatamaha river, which ſeparates it from Liberty county, and S. by Camden county. It contains 1374 inhabitants, including 1092 ſlaves. Its chief town is Brunſwick.

GLYPH, in *Architecture* or *Sculpture*, is any canal or cavity uſed as an ornament.

The Greek word is γλυφη, which literally ſignifies *graving, nitching*.

Γλυφις is properly a nitch or indenture made in graving; or, more properly, it is the notch in the end of an arrow, in which the ſtring goes.

GLYPTIC Art, the art of engraving precious ſtones. See Gems.

GLYSTER. See Clyster.

GMELIN, John George, in *Biography*, a phyſician and eminent botaniſt, was born at Tubingen on the 12th of Auguſt, 1709. He was diſtinguiſhed by his diligence and early attainments at ſchool, and at the age of fourteen was deemed ready for entrance upon the academical ſtudies of his native place. In 1727, he took the degree of doctor of phyſic, and went to Peterſburgh, whither ſome of his teachers had been invited. Here he gained many favours from Blumentooſt, the director of the academy, and was ſo highly eſteemed, that, in 1729, he was elected one of the members of the academy, and in 1731 was appointed profeſſor of chemiſtry and natural hiſtory. In 1733, he was ſelected for the department of natural hiſtory, in a commiſſion formed by the Ruſſian government, for the purpoſe of exploring the boundaries of Siberia; and ſet out on the 19th of Auguſt, with G. F. Muller, and Louis de l'Iſle de la Croyere, and a party of twenty-eight perſons, conſiſting of draughtſmen, miners, hunters, land ſurveyors, and twelve ſoldiers, with a ſerjeant and drummer. In the month of February, 1743, Gmelin returned ſafe to Peterſburgh, after having employed nine years and a half in this long and dangerous journey, which proved highly intereſting to the ſciences, and he reſumed the offices which he had before filled. In the year 1749, he entered upon a new profeſſorſhip, to which he had been appointed, on the death of Bachmeiſter, while on a viſit to Tubingen. He died of a fever in May, 1755, in the forty-ſixth year of his age. The works, which were the reſult of his travels through Siberia, obtained for him a conſiderable celebrity, eſpecially his "Flora Siberica, ſeu Hiſtoria Plantarum Siberiæ," Peterſburgh, 1747, 1749, in two parts, large 4to. with one hundred plates: the third and fourth parts were publiſhed by S. G. Gmelin. He alſo publiſhed his "Reiſe durch Sibirien," &c.; or Travels through Siberia between the Years 1733 and 1743, Göttingen, 1751, 1752, in four parts, 8vo. with plates. Gen. Biog.

Gmelin, Samuel Gottlieb, ſon of Philip Frederick Gmelin, was born at Tubingen in 1743; where he obtained both his ſcholaſtic and academical education, and graduated M. D. in 1763. He gave early proofs of genius, and during his travels in France and Holland diſtinguiſhed himſelf ſo much by his knowledge of natural hiſtory, that he was appointed profeſſor in the Academy of Sciences at Peterſburgh. Like the ſubject of the preceding article, he ſpent ſeveral years in travelling through the diſtant provinces of the Ruſſian empire, for the purpoſes of ſcientific inveſtigation; but ultimately with a leſs fortunate reſult. He was appointed, together with profeſſor Guldenſtadt, to explore the province of Aſtracan, at the time that the tranſit of Venus over the ſun's diſk was expected, and ſet out in June, 1768. Having examined the countries on the weſtern ſide of the Don, the Perſian provinces on the ſouth and ſouth-weſt ſide of the Caſpian ſea, the banks of the Wolga, and, laſtly, the eaſtern ſide of the Caſpian, ſo dangerous to travellers, he was recalled to Peterſburgh. But when he had arrived within three days journey of Kiſlar, a fortreſs on the Ruſſian borders, he was ſeized by the chan of Chaitaks; who plundered him of all his property, treated him with great barbarity, and impriſoned him. The health of Gmelin ſuffered conſiderably at this time, and he laboured under a flux, brought on by improper food and the effects of climate; yet the barbarian chief intercepted the proviſions ſent to him from Kiſlar. The empreſs gave orders that he ſhould be reſcued by force; but this was rendered impoſſible at that time by the rebellion of Pugatchef; and Gmelin died in confinement, on the 27th of

July, 1774. His death was much regretted by Catherine II., who made a liberal proviſion for his widow.

His works are; "Hiſtoria Fucorum," printed at Peterſburgh in 1768, 4to.; a ſubject to which botaniſts had paid little attention before him. "Reiſen durch Ruſsland, &c.;" or, Travels through Ruſſia, for the purpoſe of exploring the three kingdoms of nature. This work was publiſhed in ſeparate parts, as follows:—Part I. Journey from St. Peterſburgh to Tſcherkaſk, in the years 1768 and 1769. Peterſburgh 1771 with thirty-two plates. Part II. Journey from Tſcherkaſk to Aſtracan, from Auguſt 1769 to June 1770; ibid. 1774, with forty plates. Part III. Journey through the northern diſtricts of Perſia, from that period to April 1772; ibid. 1774, with fifty-one plates.—Part IV. edited after the author's death, by profeſſor Pallas, Journey from Aſtracan to Czarizyn: and alſo a ſecond Perſian Journey, 1772-74; ibid. 1786, with eighteen plates. The various and important information, contained in theſe publications, renders the imperfections of the ſtyle of this author of little moment. Gen. Biog.

GMELINA, in *Botany*, received its name from Linnæus, in honour of John George Gmelin, a native of Tubingen, profeſſor of chemiſtry and natural hiſtory at Peterſburg, who ſpent ten years in travelling through Siberia, at the expence of the Ruſſian government, and whoſe *Flora Sibirica*, in four vols. quarto, with plates, is a book of great reputation and merit. The firſt and ſecond volumes were publiſhed in his lifetime; the third and fourth long after his death, which happened in 1755, at the age of 46. He took his arrangement from Van Royen. Haller ſays the plates are unworthy of the beautiful drawings, which he himſelf had ſeen.—This genus alſo ſerves to commemorate four or five more botaniſts of the ſame family, eſpecially Samuel Theophilus Gmelin, nephew of the former, and his ſucceſſor in the profeſſorſhip, who publiſhed a *Hiſtoria Fucorum*, with plates, in 1768, one of the moſt popular books on ſubmarine botany, and who died in 1774, aged 31.—Linn. Gen 315. Schreb. 412. Willd. Sp. Pl. v. 3. 313. Mart. Mill. Dict. v. 2. Juſſ. 108. Lamarck. Illuſtr. t. 542. Gærtn. t. 56. (Michelia; Amman. in Act. Petrop. v. 8. 218. t. 18.)—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Vitices*, Juſſ.

Gen. Ch. *Cal.* Perianth very ſmall, inferior, of one leaf, nearly globular, with four ſmall unequal teeth, permanent. *Cor.* of one petal, ringent, inflated; its limb four-cleft; the upper ſegment large and vaulted; lower, and lateral ones, ſmaller, obtuſe, rounded, ſpreading. *Stam.* Filaments four; the two uppermoſt thicker and ſhorter; two lowermoſt curved upwards; anthers two-lobed; two of them ſometimes ſmaller and ſimple. *Piſt.* Germen ſuperior, roundiſh or obovate; ſtyle as long as the longer ſtamens, aſcending; ſtigma acute. *Peric.* Drupa ovate, of one cell. Nut obovate, ſmooth, of three cells, the lowermoſt abortive. *Seeds* ſolitary.

Eſſ. Ch. Calyx with four ſlight teeth. Corolla four-cleft, ringent, bell-ſhaped. Anthers cloven. Drupa ſuperior. Nut of two fertile cells.

1. G. *aſiatica*. Linn. Sp. Pl. 873. Burm. Ind. 132. (Jambuſa ſylveſtris parvifolia; Rumph. Amb. v. 1. 129. t. 40.)—Leaves roundiſh, ſomewhat three-lobed, acute, downy beneath.—Native of Java, Amboina, and other parts of the Eaſt Indies. A *tree*, with ſtraight, roundiſh, ſlightly downy branches. *Leaves* oppoſite, ſcarcely two inches long, of a roundiſh or elliptical form, acute, moſt generally furniſhed with a ſhort broad lobe at each ſide, entire; ſmooth above; pale and downy beneath; the midrib ſending off two principal lateral ones, a little above its baſe, and ſeveral ſmaller ones higher up, all which are branched. *Footſtalks* downy, various in length, often nearly equal to the leaf, each with a ſmall hairy bud above its inſertion, and above that uſually a ſtraight, downy, horizontal ſpine. *Flowers* in a ſhort, ſimple, downy, terminal *racemus*. *Calyx* downy, beſprinkled with ſeveral large, ſhield-like, ſmooth glands. *Corolla* large, yellow.

Rumphius's figure unqueſtionably belongs to this plant, but his deſcription ſeems that of an *Eugenia*. Plukenet's t. 305. f. 3. is certainly *Gardenia dumetorum*, and reſembles our *Gmelina* only in being thorny; his t. 97. f. 2. may poſſibly be intended for *Gmelina parvifolia*, but is of no uſe as to determining it.

2. G. *elliptica*.—Leaves elliptical, undivided, obtuſe, downy beneath. Thorns none.—Native, we preſume, of the Eaſt Indies, confounded in the Linnæan herbarium with the foregoing, from which it differs in having rather larger *leaves*, which are exactly elliptical and blunt, more denſely downy beneath, and not lobed. There are no traces of thorns. The *infloreſcence* is rather more compound, but the remarkable glandular *calyx* is the ſame. If a variety it is a very extraordinary one.

3. G. *parvifolia*. Roxb. Corom. v. 2. 31. t. 162. (G. coromandelica; Burm. Ind. 132.)—Leaves obovate, undivided or three-lobed, ſmooth on both ſides.—Common in every foreſt and uncultivated place on the coaſt of Coromandel, flowering in October and November. *Roxburgh.* It is often intermixed with G. *aſiatica*, from which it differs in its more humble ſize, larger and conſtant *thorns*, and eſpecially in its ſmaller *leaves*, which are ſmooth on both ſides. Their *flowers* and *fruits* are alike, the latter being yellow, obovate, the ſize of a ſmall cherry. We perceive on one calyx in our ſpecimen a ſolitary gland, like thoſe deſcribed in the two former.—Dr. Roxburgh mentions that cold water, ſtirred with a leafy branch of this ſhrub, becomes thick, from the abundant mucilage of the leaves, and is uſed in that ſtate as a remedy for the heat of urine which accompanies gonorrhœa. Water ſtirred with branches and leaves of *Pedalium Murex* becomes in like manner mucilaginous, and is uſed for the ſame purpoſe, but ſoon loſes its conſiſtency, which is not the caſe with ſuch as is prepared with this *Gmelina*. The Telingas call the plant *Shieri goomoodoo*. It may poſſibly be Plukenet's *Lycium Maderaſpatanum*, t. 97. f. 2, as Burmann takes it to be, but Sloane's *Rhamnus*, Hiſt. of Jamaica, v. 2. t. 207. f. 1, cannot be the ſame, though his vile figure affords no diſtinct indication of what he means.

4. G. *arborea*. Roxb. MSS. (Cumbulu; Rheede Hort. Mal. v. 1. 75. t. 41.)—Leaves heart-ſhaped, undivided, pointed, downy beneath; their lateral ribs cloven. Thorns none.—Sent from the coaſt of Coromandel by the Rev. Dr. Rottler, with the above name of Dr. Roxburgh. Gærtner has moſt juſtly pointed out the *Cumbulu* of Rheede as a *Gmelina*, though quoted by Linnæus, doubtingly indeed, for his *Bignonia Catalpa*. This is a tall and upright *tree*, growing in ſandy ground, with downy *branches*, and large, oppoſite, ſtalked, heart-ſhaped, entire *leaves*, downy and veiny beneath. *Thorns* none, as far as we can learn. The *flowers* are numerous and handſome, yellow, growing in compound, hairy, terminal cluſters. *Fruit* yellow, obovate, rather ſmall.

5. G? *indica*. Burm. Ind. 132. t. 39. f. 5. (*Doery Zoekan* of the Malays.) Leaves alternate, heart-ſhaped, crenate, ſmooth on both ſides.—Native of Java. *Herb. Linn.* A *ſhrub* or *tree*, with round, ſomewhat zig-zag, ſlightly downy branches. *Leaves* from half an inch to an inch long, alternate, on ſhort hairy ſtalks, veiny, bluntly crenate. *Thorns*

ſtraight, ſlender, acute, moſtly longer than the leaves. The *flowers* and *fruit* ſeem to be unknown. We have only Burmann's very feeble authority for making this a *Gmelina*, which its alternate crenate leaves ſtrongly diſcountenance, nor did Linnæus ever venture to adopt it. S.

GMUND, in *Geography*. See Gemunden.

GNAA, a town of the duchy of Stiria; 24 miles S.E. of Gratz.

GNADENHUETTEN, a ſettlement of the Moravians in America, ſituated on Muſkingum river, oppoſite to Salem, in the lands which belonged to the Mahikan Indians.—Alſo, the name of a Moravian ſettlement, on the S.W. bank of Lehigh river, in Pennſylvania, about 29 miles N.W. of Bethlehem.—Alſo, a Moravian ſettlement, called *New Gnadenhuetten*, on Huron river, about 22 miles from lake St. Clair, in the county of Wayne, and 28 N.W. of Detroit.

GNAPEEZEIK, a town of Birmah, on the Irawaddy; ſo called from Gnapee, or Napee, a ſort of ſprat, half pickled and half putrid, uſed as a ſauce by the Birmans, and forming an extenſive branch of trade: 110 miles N.N.W. of Rangoon.

GNAPHALIUM, in *Botany*, γναφαλιον, an ancient Greek name, from γναφαλον, *ſoft down* or *wool*, ſuch as is plucked from cloth in dreſſing it, alluding to the woollineſs of the herbage. Many writers have contended that *Santolina maritima* of Linnæus, and Sm. Fl. Brit. 860, is the true γναφαλιον of Dioſcorides, an opinion extremely difficult to eſtabliſh or to contradict, as all he ſays of it is, that "its leaves are white and ſoft, uſeful for ſtuffing." However this may be, Tournefort, and lately Gærtner, have retained that plant, as the true and only ſpecies of *Gnaphalium*. The *Gnaphalium* of Linnæus however is a very extenſive and comprehenſive genus, from which ſome ſpecies have of late been ſeparated. See Elichrysum.—Cud-weed.—Linn. Gen. 419. Schreb. 550. Willd. Sp. Pl. v. 3. 1849. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 173. Sm. Fl. Brit. 867. Juſſ. 179. (Elichryſum; Gærtn. t. 166. Antennaria; Gærtn t. 167. Anaxeton; Gærtn. t. 166? Filago; Gærtn. t. 166. See Filago.) Claſs and order, *Syngeneſia Polygamia-ſuperflua*. Nat. Ord. *Compoſitæ Nucamentaceæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* imbricated, rounded; ſcales numerous, the marginal ones rounded, ſcarioſe, coloured. *Cor.* compound; *florets* of the diſk perfect, tubular, funnel-ſhaped, in five equal reflexed marginal ſegments; ſome female ones, without a corolla, are often intermixed towards the margin. *Stam.* (in the perfect florets) Filaments five, very ſhort, capillary; anthers forming a cylinder. *Piſt.* (in the ſame florets) Germen ovate; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma cloven. In the female ones the ſame. *Peric.* none, except the permanent ſhining calyx. *Seeds* in both kinds of florets alike, ſolitary, oblong, ſmall, crowned with capillary or feathery down. *Recept.* naked.

Eſſ. Ch. Receptacle naked. Down capillary or feathery. Calyx imbricated, its inner ſcales rounded, ſcarioſe, coloured.

Willdenow reckons 146 ſpecies of *Gnaphalium*, of which 32 are ſhrubby, with ſilvery, white or crimſon flowers, or rather without any golden tinge; 12 are of a yellow or golden colour, likewiſe ſhrubby; 19 are herbaceous, with yellowiſh flowers; 28 herbaceous, with white or reddiſh ones; and 29 have the inconſpicuous whitiſh bloſſoms of the *Filago* family. The remaining 26 are ſpecies defined by Thunberg, without any attention to theſe leading ſections of the genus, ſo that it is impoſſible to ſay to which they belong. Ten ſpecies, all herbaceous, are deſcribed as natives of Britain.

In this large genus it is by no means certain that all the ſpecies correctly anſwer to the generic character, particularly in the receptacle, which is not always ſtrictly naked, but bears a few briſtles towards the margin, thus becoming an *Anaxeton* of Gærtner.

The marginal ſcales alſo, being ſometimes a little pointed and reflexed, intrench upon the proper character of *Elichryſum*; ſee that article. In fact theſe genera are naturally one and the ſame, but, on account of their great extent, are conveniently ſeparated by the character, though an imperfect one, of the more radiating calyx of *Elichryſum*. Linnæus's error conſiſted in referring the latter to *Xeranthemum*, which has a different habit and a chaffy receptacle.

The firſt ſpecies in Willdenow, G. *eximium*, Linn. Mant. 573. Curt. Mag. t. 300, is one of the moſt ſplendid. The *leaves* are clothed with very thick white wool, and the ſhrubby ſtem is terminated by a large corymbus of *flowers*, whoſe calyx is the ſize and ſhape of a raſpberry-fruit, of a rich ſhining crimſon. The *florets* are orange-coloured. It grows about 500 miles up the country above the Cape of Good Hope, and was for a long time known to European botaniſts merely by dried ſpecimens, (one of which is figured by Edwards in his Hiſtory of Birds, t. 183), brought occaſionally to the Cape by the diſtant ſettlers.

Several others of the ſhrubby kinds are very ornamental to our green-houſes.

Of the herbaceous ſorts G. *fœtidum*, whoſe flowers, uſually yellow, are occaſionally white or ſilvery, always very ſplendid, is one of the moſt remarkable, but the ſtrong ſmell of its viſcid herbage when touched is offenſive to moſt people. G. *orientale* is ſomewhat ſhrubby, though ranged with the herbaceous ones. Its ſhining lemon-coloured flowers frequently ſerve for ornamental purpoſes, and are known by the name of *Everlaſting*, a name appropriate to the whole genus.

G. *margaritaceum*, Engl. Bot. t. 2018, ſerves in Wales, where it grows wild, to adorn the graves of the departed, elegantly alluding to immortality by the unfading nature of its flowers, and to ſpotleſs purity by their ſnowy whiteneſs. This plant is often cultivated in cottage gardens.

G. *dioicum*, Engl. Bot. t. 267, the *Antennaria* of Gærtner, ſo called from its plumy crown to the ſeed, is one of our moſt elegant ſpecies, found on dry rather mountainous heaths. The *flowers* are of a beautiful roſe-colour.

The Cape of Good Hope is moſt fertile in this genus, but ſeveral fine ſpecies grow in South America, and there are ſome from New Holland to be added to what are enumerated in Willdenow. The mountains and fields of different parts of Europe produce various ſpecies, but few of the more handſome, except G. *arenarium*, Fl. Dan. t. 641, and its near relation G. *olympicum* of our gardens, gathered about the Bithynian Olympus by Dr. Sibthorp; both which vie with G. *orientale* in their ſhining golden or lemon colour, and the *olympicum* at leaſt is a hardy perennial, of eaſy culture.

Gnaphalium, in *Gardening*, affords plants of the herbaceous and under ſhrubby kinds: of which the ſpecies moſtly cultivated are, the tree everlaſting (G. arboreum); the red-flowered everlaſting (G. igneſcens); the eaſtern everlaſting, or immortal flower (G. orientale); the ſweet-ſcented everlaſting, or eternal flower (G. odoratiſſimum); the American everlaſting, or eternal flower (G. margaritaceum);

taceum); the plantain-leaved everlaſting (G. plantagineum); the common ſhrubby everlaſting, or ſtæchas (G. ſtæchas). Many of theſe are curious plants.

Method of Culture.—The firſt four ſorts may be increaſed by ſlips from the heads or cuttings; by planting them in pots of light earth in the ſpring or ſummer months, and plunging them in a moderate hot bed, refreſhing them often with water. When they have taken full root, they may be removed into ſeparate pots, and be placed among other plants of the hardy exotic ſort. They require the protection of a frame in the winter ſeaſon.

The ſeventh ſpecies may be increaſed in the ſame manner, being placed at once where it is to remain, in a ſhady ſheltered border, or other place that is proper.

The fifth and ſixth ſorts may be eaſily raiſed by dividing and planting their creeping roots where they are to grow, either in the autumn or ſpring months.

Theſe three laſt are ſufficiently hardy to ſtand the open air in warm ſituations.

They are all ornamental plants, the former in the greenhouſe collection, and the latter in the open ground.

GNAPHEUS, in *Ichthyology*, a name given by Athenæus and other of the Greek writers to the tench.

GNARP, in *Geography*, a town of Sweden, in the province of Helſingland; 20 miles N. of Hudwickſwal.

GNAT, in *Entomology*. See CULEX.

There is no ſpecies of inſect that we have ſo much reaſon to diſlike in regard to the injury it does us as the gnat. Others indeed give us more pain with their ſtings, but it is but by accident that we are ſtruck by them; the gnats thirſt for our blood, and follow us about in whole companies for it. There are many marſhy places where the legs and arms are all the ſummer ſwelled to an enormous ſize by the repeated bitings of theſe inſects, and in many other countries they are much more troubleſome than with us.

But as troubleſome enemies as theſe little creatures are to us, there is that about them which is extremely worthy our admiration; nor can we indeed fail greatly to admire even the very inſtrument of the miſchief they do. They have beſide this many very obſervable particulars in the courſe of their lives.

All the naturaliſts of late years have applied the microſcope to the examination of the parts of this little animal, and Swammerdam, Hook, Bonanni, Leeuwenhoeck, &c. have given very good accounts, and very valuable drawings of the creature.

There is a great number of very ſmall ſpecies of gnats, and though ſome are conſiderably large, yet none even of theſe approaches to the ſize of the tipula, or father long-legs, as commonly called. The larger tipulæ are therefore eaſily diſtinguiſhed from the gnats; but Swammerdam, Goedart, Liſter, and others, have very often given us the ſmaller tipulæ among the ſpecies of gnats. Both have long ſlender bodies, and both prominent corcelets, which make them look hump-backed; but when either of theſe inſects is taken into the hand it is very eaſily known, the gnat having a very long trunk, and the tipula no trunk at all.

There is a prodigious number of ſpecies of the gnat kind, comprehending the ſmaller ones; Dr. Derham obſerved near forty different ſpecies about Upminſter in Eſſex: but of thoſe of a ſize to be remarked with eaſe, and without the help of glaſſes, there are three principal kinds: the one has its body variegated with white and black; this is the larger kind, and its corcelet is ſtreaked with black or deep brown, and white lines or greyiſh ones; theſe have brown eyes; another is ſmaller than this ſpecies, and has a plain brown body, the colour of the corcelet, and that of the eyes is the ſame as in the larger or firſt ſpecies; the third kind is the ſmalleſt of the three and the moſt common, has its corcelet reddiſh, or of a faded reddiſh yellow, and the body whitiſh, and on the under part of the belly every ring has one ſingle brown ſpot; the reſt is grey: the eyes of this ſpecies are of a very pleaſant green.

All the gnats have a long cylindric body compoſed of eight rings; their corcelet is ſhort but large, in proportion to the ſize of the fly, and to this are fixed the ſix legs, which are hairy, with ſix joints to each, and at the end two little claws, the wings, and the balancers: four ſtigmata are alſo found here, as is the caſe in other flies: the two firſt of theſe are placed near the head, and have been miſtaken for ears.

The antennæ of gnats are extremely worth obſervation, and differ much from one another. Some of them are elegantly feathered; theſe belong to the males of certain ſpecies, for the antennæ of the females are not ſo beautiful. The bruſh-horned or male gnat has two pair, one of which is ſurrounded, at ſmall diſtances, with long hair, iſſuing out circularly, each circle leſſening as it approaches the extremity of the antennæ; the other pair are longer and much thicker, and hairy from end to end. In the great bellied or female gnat, the firſt pair of antennæ, though of the ſame figure as the male's, has hairs not near ſo long, and the ſecond pair is ſhorter than the firſt by at leaſt three parts in four. Reaumur, Hiſt. Inſ. vol. iv. p. 574, &c. Baker's Microſ. 1743. p. 203, &c. For the trunk and wings of the gnat, ſee TRUNK and WINGS.

GNATS, *Eggs of*. See EGGS.

For the *Eyes of* GNATS, ſee EYES *of Flies*.

GNAT-*worm*, in *Natural Hiſtory*, a ſmall water inſect, produced of a gnat, and which is, after its ſeveral changes, transformed into a gnat again.

From the eggs, depoſited by the gnat on the ſurface of the water, proceed a number of minute worms, which ſinking to the bottom of the water, form for themſelves coverings of fine ſand or earth, cemented together with a ſort of glue, but open at both ends, that they may come out and enter as occaſion requires.

Theſe worms do not frequent rivers; but ditches, ponds, and other ſtanding waters, afford them in vaſt abundance, from the middle of May till toward the beginning of winter. This is the reaſon why watery and marſhy places are found moſt to abound with gnats, and why the wet ſummers are found to produce the greateſt numbers of them; becauſe in dry ſeaſons, the ponds and ditches, where they are to paſs their worm-ſtate, are dried up, and the worms killed. Theſe are creatures, however, that one need not go far to ſeek, ſince a veſſel of water, expoſed in any open place in the ſummer months, will not fail to afford plenty of theſe worms in a little time.

Before theſe worms are arrived at their full growth, though they are then but ſmall, they are eaſily found, becauſe they are under a neceſſity of coming frequently to the top of the water, by having occaſion for frequent reſpiration; and to do this, they are obliged to keep the end of a ſmall pipe they are furniſhed with, from the laſt ring of their body, above water. The end of this pipe is hollow and indented, and forms a ſort of funnel on the ſurface of the water: it is of the length of about three rings of the body, and is ſomewhat thicker at its inſertion than at its extremity.

As there is a vaſt number of ſpecies of gnats, there is no leſs of the worms from whence they are produced: and to this is in a great meaſure owing the variety in the figures given of the worms by the authors who have treated of them; which may alſo be not a little added to by the particular views in which thoſe draughts have been taken. Notwithſtanding all the variations of theſe figures, the general form of the animal is however the ſame in all, and the ſpecies cannot but be known from any of them. While the worm is young, the body is whitiſh or greeniſh; but when it is at its full growth, and draws near the time of its changes, it becomes greyiſh. The great tranſparence of the body of this worm gives a fine view of what paſſes within it; it is at any time eaſy to ſee into the motion of the inteſtines, by which the food is puſhed on towards the anus. The two principal tracheæ are alſo ſeen very diſtinctly in this creature; they are two white tubes placed in a parallel direction one to another, and run from the firſt ring to the tube of reſpiration.

The great worm ſeveral times changes its ſkin in the courſe of its life. After three changes of this kind, which uſually happen in the ſpace of three weeks, or thereabout, it undergoes a fourth, where the old ſkin is as eaſily thrown off as in the reſt, but the animal now appears in a new form, that of a nymph; it is now ſhorter and rounder than before, and the body is ſo bent that the tail is applied to the under part of the head; this, however, is only its form in a voluntary ſtate of reſt, for it can yet move, and when it pleaſes extends its tail, and ſwims about as ſwiftly as when in its other ſtate.

When the creatures have quitted their firſt habitations and the figure of worms, they re-aſcend to the top of the water, incloſed in a kind of ſhell, with a large head and mouth, two black eyes, two horns, ſeveral tufts of hairs on different parts of the body, and a tail with a bruſh of hair at the end of it, which, being ſmeared over with an oily fluid, ſerves to keep them above water; their heads being ſometimes lifted in the air, and ſometimes plunged into the water, while the tail ſlides along the ſurface: and when the oil on the tail begins to dry, they ſhed from their mouth a freſh ſupply, which renders it capable of ſteering where they pleaſe, without being wetted and damaged by the water.

All the parts of the future gnat may be ſeen in this nymph; the ſkin of it is extremely thin and tranſparent, yet ſufficiently tough and firm for the uſe it is intended for. It is uncertain how long exactly the animal lives in this nymph ſtate; but after the time is accompliſhed, its change into a gnat is very quick, and is attended with great danger to the animal, ſince multitudes are drowned in the act of getting out and ſpringing into the air. Reaumur, Hiſt. Inſ. vol. iv. Baker's Microſ. 1743. p. 88.

Gnat, in *Rural Economy*, a ſmall well-known inſect, which is ſaid to deſtroy the leaves of ſome tender vegetables as ſoon as they appear, ſuch as the turnip, &c.

GNEISS, in *Mineralogy*, a primitive rock, compoſed of feldſpar, quartz, and mica; ingredients which are likewiſe thoſe of granite, from which it differs in the arrangement of thoſe parts; for while in the latter rock they uſually appear as granular aggregations, thoſe of gneiſs are diſpoſed in ſuch a manner as to exhibit a more or leſs ſlaty ſtructure. This ſtructure paſſes through various degrees of diſtinctneſs; on one hand it approaches ſo near to the granular texture, that the diſtinction between gneiſs and granite ceaſes to exiſt, while, on the other hand, when its peculiar texture is very obvious, and becomes what is termed *thin ſlaty*, a paſſage is formed into the primitive rock, next to it in antiquity, called mica-ſlate. In its progreſs towards the nature of granite, the feldſpar is generally predominant with regard to the mica; while thoſe varieties approaching mica-ſlate gradually exhibit a ſmaller proportion of feldſpar and much mica. Sometimes, however, the mica is only apparently predominating, owing to the circumſtance, that on breaking a maſs of gneiſs, the line of ſeparation will more frequently paſs through the mica than through the other layers, and diſplay a whole ſurface of that ſubſtance; but another fracture, perpendicular to the firſt, will, in this caſe, ſoon undeceive the obſerver. Though feldſpar is, generally ſpeaking, the predominant ingredient of gneiſs, yet the proportion of mica in this rock is, upon the whole, greater than what we ſee it in granite: and the leſs this is the caſe, the more the maſs appears granular, and the more it approaches to granite. It is often a matter of difficulty, in viewing ſmall ſpecimens only, to diſtinguiſh ſome kinds of gneiſs from the laſt-mentioned primitive rock; when the inſpection of the former in their natural ſituation, and on a large ſcale, would have left but little doubt in the mind of the examiner.

Gneiſs, viewed in the large, as a mountain maſs, always exhibits thick and diſtinct ſtrata, whoſe outgoings, or upper terminations, are generally lower than the ſubjacent granite, and higher than thoſe of the ſuperincumbent mica-ſlate.

Werner (to whom we owe more correct ideas reſpecting this rock,) diſtinguiſhes four kinds of gneiſs, *viz.* that approaching the granular ſtructure, the waved or undulated, the common, and the thin ſlaty gneiſs. As particular varieties of theſe, we have 1. The ſtriped gneiſs, in which the quartz is diſpoſed in narrow bars, ſurrounded by feldſpar, producing, on its longitudinal fracture, a ſtriped appearance, not unlike that of ſome kinds of petrified wood; while its tranſverſal fracture exhibits a granular diſpoſition of the parts. This ſtriped variety generally occurs together with the waved; ſuch as at Ober-Newſhönberg, Reiſland and Hartmanſdorf, near the Bohemian frontiers. 2. The ſprinkled, or that kind of gneiſs in which the feldſpar and mica exhibit themſelves in the form of ſmall neſts: ſuch as that found at Hartmanſdorf and Bobritſch, near Freiberg, and at Kuffenberg in Bohemia. 3. The ſhort lamellar or flaky variety, ſuch as it is found at Marienberg.

The *colour* of the ingredients of gneiſs is not ſubject to great variation. The feldſpar is generally of a greyiſh, yellowiſh, and reddiſh-white colour, ſeldom yellowiſh-grey, or deep fleſh-red, as it appears in many varieties of granite; upon the whole, its tint reſembles that of the quartz with which it is accompanied, and which ſeldom appears ſmoke-grey or brown. The colour of the mica is generally black or browniſh-black, ſometimes browniſh, yellowiſh, and aſh-grey, and rarely ſilver-white or of a golden hue.

Theſe component parts are found to vary alſo in regard to their *freſhneſs*; in general the feldſpar is perfectly foliated and ſhining; but ſometimes it appears in incipient decompoſition, or even converted into petunze; in the ſame manner as the mica is now and then ſeen paſſing into a greeniſh ſubſtance reſembling ſteatite. Dr. Reuſs found that the porcelain earth dug at the Galgenberg, near Puſchwitz, in the Saatz diſtrict of Bohemia, where it is uſed for white-waſhing walls, is the reſult of the higheſt ſtage of decompoſition of gneiſs; it forms thick ſtrata, and contains a great quantity of ſmall greyiſh white, light grey, and pale clove-brown grains of quartz. In the ſame manner this mineralogiſt obſerved in that country frequent proofs of the converſion of the feldſpar of gneiſs into a ferruginous clayey maſs. Near Kloſterly it is ſeen converted into bunt-thon or variegated clay.

Beſides the more eſſential feldſpar, quartz, and mica, the following *accidental ingredients* are now and then met with in gneiſs. 1. Shorl: both the common and black tourmaline ſhorl, ſometimes occur in the gneiſs of Freiberg, and particularly of Spain. 2. Garnet: rarely, but much more frequently than in granite; it occurs at Wieſenthal in Saxony, in Norway, in the iſland of Zealand, in Moravia, &c. 3. Hornblende

blende: is but ſeldom found, and only in the thin flaty variety of gneiſs, which paſſes into mica and hornblende ſlate. 4. Steatite: occurs principally in the gneiſs forming the walls of the metalliferous veins in the Freiberg diſtrict; it is conſidered by ſome as mica thus transformed by ſulphuric acid. 5. Actinote: is ſaid ſometimes to conſtitute an ingredient of gneiſs in Switzerland and Hungary. Metallic ſubſtances that are ſometimes found diſſeminated in gneiſs, in the vicinity of veins, cannot properly be enumerated even as accidental component parts of this rock.

Gneiſs abounds in metals more than any other rock, as may be ſeen from the richneſs of the Saxon and Bohemian mines, thoſe of Salzburg, &c. There are but few among the known metals that are not found in it, either in veins or beds. "The oldeſt gneiſs in the Saxon Ertzgebirge," ſays Mr. Jameſon, "that with reddiſh-coloured feldſpar, is the leaſt productive in ores; but the newer, with white coloured feldſpar, is the moſt productive; and the veins, though ſmall, are numerous. The oldeſt venigenous formation appears to be that which contains tin-ſtone. The tin-ore is accompanied with wolfram, molybdena, arſenic-pyrites, fluor-ſpar, chlorite, topaze, and opal. The ſecond venigenous formation appears to be a lead-glance formation. The third formation conſiſts principally of copper, and the ores are grey copper-ore, copper-glance, copper-pyrites, and variegated copper-ore. The fourth formation, which is very extenſive, contains ores of cobalt. The neweſt formation is that which contains ores of ſilver. Veins containing antimony, and red iron-ſtone occur in gneiſs, and theſe are ſuppoſed to be newer than any of the preceding. The metalliferous beds that occur in this rock contain argentiferous lead-glance, blende, copper and iron-pyrites. It ſometimes alſo contains formations of gold."

There are three conſiderable beds of *rocks ſubordinate* to, and ſynchronic with, gneiſs, and which are therefore not ſeen in granite, *viz*. granular limeſtone, as it is obſerved, for inſtance, near Freiberg; primitive trap, ſuch as hornblende-ſlate, at Kuttenberg in Bohemia, at Kongſberg in Norway, &c.; and the older porphyry. (See LIMESTONE, TRAP, and PORPHYRY.) Alſo ſmall beds of common garnets, actinote, with magnetic iron-ſtone, iron-pyrites, galena, &c. now and then occur in gneiſs.

Gneiſs being generally ſuperincumbent on granite, is hence conſidered as next to this primitive rock in point of *age*: there is, however, alſo a difference in the relative antiquity of the different kinds of gneiſs, and on the whole it may be ſaid that the nearer it approaches in its texture to *Mica-ſlate*, (ſee that article,) the more recent is its origin. From this it does not, however, follow that there ſhould not be found kinds of gneiſs which ſurpaſs in antiquity even ſome kinds of real granite. (See GRANITE.) The very thick flaky varieties of gneiſs, with black mica and a ſmall proportion of mica, may, in general, be ſaid to be of more ancient formation.

Gneiſs, though far leſs widely diſtributed than granite, has ſtill a conſiderable range; it extends over the greateſt part of the Saxon Ertzgebirge: the country about Freiberg, Glaſhütte, Marienberg, Ehrenfriederſdorf, conſiſting almoſt entirely of it. In the ſame manner it is the characterizing rock of the Bohemian mountainous mining diſtrict. It is alſo found in Sileſia, Carinthia, in ſome parts of the Black Foreſt in Suabia; nor is it wanting in the Tauriſkian mountains, in Salzburg, in the Swiſs Alps, the Pyrenees and Voſges, in Scandinavia, Greece, &c. In Great Britain it has been obſerved particularly in Scotland, in the iſlands of Coll, Tiree, Rona, and in the Shetland iſlands. It ſhould however be obſerved, that frequently other rocks have been deſcribed as gneiſs by topographical writers.

The *economical uſe* made of gneiſs is that for paving, and for the conſtruction of walls; for both which purpoſes it is extremely well calculated, by reaſon of the facility with which it is wrought by the maſon. Hence in the Saxon mining diſtrict not only almoſt all buildings are conſtructed of gneiſs, but alſo the walling of the ſhafts and levels is moſt advantageouſly executed in this uſeful rock.

GNEMON, in *Botany*, a tree ſo called in the iſland of Ternate and others of the Moluccas, which is named in the Malay language *Meninjo*, or *Meningo*, a word apparently of the ſame derivation, whatever that may be. See GNETUM.

GNERDEN, in *Geography*, a town of Perſia, in the province of Irak; 150 miles E. of Iſpahan. N. lat. 32° 20'. E. long. 55°.

GNERROUTOOH, a town of Birmah, on the Irawaddy; 10 miles N. E. of Pagham.

GNESEN, or GNESNA, a city of Poland, in the duchy of Warſaw, built, as it is ſaid, by king Lechus I., founder of the monarchy, and called *Gneſna*, from an eagle's neſt found there, denominated in the Poliſh language *Gneſiad*. The kings of Poland were crowned in this city, and the regalia were kept here till, in the year 1320, they were removed to Cracow. During the independent exiſtence of Poland, it was famous as the ſee of an archbiſhop, who was primate of Poland, and who acted as interrex or regent upon the king's demiſe; and who alſo announced the event, convoked the diets and dietines of convocation, and performed the functions of royalty. Gneſna is 100 miles N. E. from Breſlaw, and 130 W. from Warſaw. N. lat. 52° 26'. E. long. 17° 42'.

GNETUM, a name contrived by Linnæus, as we preſume from [illegible], *brotherhood*, alluding to the ſituation of the numerous male and female flowers, ſeveral of each together in each whorl. Linn. Mant. 18. Schreb. 659 Willd. Sp. Pl. v. 4. 591. Mart. Mill. Dict. v. 2. Juſſ. 406. (Thoa; Aubl. Guian. v. 2. 874. Schreb. 650 Juſſ. 406. Lamarck Illuſtr. t. 784.) Claſs and order, *Monœcia Monadelphia*. Nat. Ord. *Urticis affine*, Juſſ. or rather, as he himſelf hints, to be referred to a new order, which he propoſes to term *Piperes*.

Gen. Ch. *Cal.* Catkin compoſed of ſeveral remote, callous, thickened whorls, each ſubtended by a ſmall *partial calyx*, which is peltate, orbicular, flat, entire, containing ſeveral ſeſſile florets, the male ones inferior, the females ſuperior, in the ſame whorl. Perianth of the male a minute, ovate, coloured ſcale. *Cor.* none. *Stam.* Filament one, thread-ſhaped, longer than the ſcale; anthers in pairs, connected.

Perianth of the female a rude, lacerated ſcale. *Cor.* none. *Piſt.* Germen ovate, ſuperior, immerſed in the receptacle of its own whorl, the length of the ſtamens; ſtyle conical, ſhort; ſtigma three-cleft, acute. *Peric.* Drupa ovate, of one cell. *Seed.* Nut ſolitary, oblong, ſtriated, of one cell.

Eſſ. Ch. Male, Calyx an undivided ſcale of a whorled catkin. Corolla none. Filament one, with a pair of anthers. Female, Calyx a torn ſcale of the ſame whorl. Corolla none Stigma three-cleft. Drupa with one ſeed.

Obſ. Linnæus obſerves that Rumphius makes his plant diœcious, but he found it monœcious, and even ſaw one catkin entirely male, ſtanding on its own footſtalk, near a female floret. The *Thoa* of Aublet, though ſomewhat differently deſcribed, is undoubtedly the ſame genus, and indeed ſo like the original *Gnetum* in foliage, that it is not very eaſy to diſtinguiſh them.

1. G. *Gnemon*.

1. G. *Gnemon.* Linn. Mant. 125. (Gnemon domeſtica; Rumph. Amboin. v. 1. 181. t. 71, 72. Beretinus fructus; Cluſ. Exot. 55.)—Lateral veins of the leaves prominent, inter-branching archwiſe half way towards the margin. Catkins oppoſite, axillary, on ſimple ſtalks.—Native of the Molucca iſlands, and other parts of the Eaſt Indies. We have it from Java. A *tree*, with ſtraight, round, ſlender, ſmooth *branches*, ſwelling at each joint, under the inſertion of the leaves, and ſomewhat forked at the ends. *Leaves* oppoſite, ſtalked, ovate, inclining to lanceolate, pointed, entire, ſmooth and ſhining, three or four inches long, furniſhed with a midrib, channelled above, prominent beneath, ſending off ſeveral alternate, ſpreading, prominent though ſlender veins, which meet rather more than half way towards the margin in one common arching vein, whence numerous reticulations originate. *Stipulas* none. *Footſtalks* half an inch long, channelled and keeled. *Catkins* axillary, ſhorter than the leaves, two together from each oppoſite leaf, on ſimple ſtalks, their whorls when young crowded, but ſoon becoming diſtant and bead-like, every whorl bearing numerous female as well as male flowers. What Linnæus deſcribes as a torn ſcale in the former, ſeems rather a very denſe aſſemblage of ſhort tufted fibres. *Fruit* the ſize of an ordinary acorn or filberd, its coat thin, ſweetiſh according to Rumphius, but with too much acrimony to be eaten raw; as is alſo the caſe with the leaves, which, when dreſſed, are in almoſt daily uſe among the natives of Amboyna, though thought mawkiſh and inſipid by Europeans.

2. G. *Thoa.* (Thoa urens; Aubl. Guian. v. 2. 874. t. 336.)—Lateral veins of the leaves obſolete, inter-branching archwiſe. Catkins on ſimple ſtalks, from the repeated forks of the branches.—Gathered by Aublet in the woods of Guiana, where the natives call it *Thoa.* His own ſpecimen in our poſſeſſion has no fructification nor infloreſcence, ſo that we have been obliged to take part of our character from his figure. The *leaves* ſeem in general to be rather ſhorter and broader than in the former, but the chief diſtinction is obſervable in their lateral veins, which though they do in a ſimilar manner run into one common arching vein, above half way towards the margin, are all together far more ſlight and leſs prominent than in the firſt ſpecies. The *fruit* is like the former, reddiſh, and elliptical. Aublet ſays that when its outer ſkin is taken off, a dry ſubſtance is found underneath, compoſed of ſtiff depreſſed hairs, which eaſily ſeparate from each other, and if any of them fall upon the human ſkin, they cauſe a great itching. The kernel of the nut, boiled or toaſted, is good to eat. Birds of the fowl or pheaſant tribe feed in the woods upon this fruit, which they ſwallow whole. The ſame author aſſures us that a clear gum iſſues from the bark and branches, but that when the main trunk or great branches are cut, a clear taſteleſs watery liquor runs out, which may be drank by thoſe who are diſtreſſed for water. This tree is almoſt always in flower and fruit. Aublet deſcribes the catkins as male, with two female flowers at their baſe. This is ſo different from our ſpecimens of *G. Gnemon*, that it might almoſt afford a ſpecific character, but Rumphius deſcribes the ſame circumſtance in what he terms his male *Gnemon*, and Linnæus adverts to ſomething like it. It ſhould ſeem therefore that in the firſt, if not in every ſpecies, the genus is imperfectly diœcious, one tree bearing catkins with female flowers, with perhaps leſs perfect males, in every whorl, while on another are found more efficient males in every whorl, with females at the baſe only, as in Aublet's *Thoa.* Such examples throw great light on the phyſiology of vegetable generation, and confirm the Linnæan theory.

3. G. *funiculare.* Buchanan MSS. (Gnemon funicularis; Rumph. Amboin. v. 5. 12. t. 8. Ula; Rheed. Hort. Mal. v. 7. 41. t. 22.)—Lateral veins of the leaves ſeparate to the margin. Catkins oppoſite, axillary, on branched ſtalks.—Native of Amboyna and other places in the Eaſt Indies. This is a long trailing branched ſmooth *ſhrub*, turning black in drying, which the two former do not. The *leaves* are four or five inches long, various in breadth, pointed, firm, ſhining, diſtinguiſhed by their veins continuing diſtinct to the edge of the leaf. The *flower-ſtalks* are axillary, in pairs, more or leſs branched and forked; each catkin being about an inch long, compoſed of numerous orbicular imbricated ſcales concealing the flowers, and not unaptly compared in the Hortus Malabaricus to Long Pepper. Each ſtands on a partial ſtalk, of about its own length. The *fruit* reſembles that of the foregoing, and is roaſted over the fire, which renders the kernel eatable. The tender leaves ſerve for a pot-herb, like thoſe of *G. Gnemon.* The bark of the young twigs, ſplit into thread, ſerves to make nets.

Rumphius's vol. 5. t. 7, which he calls *Funis Gnemoniformis*, but of which he ſeems not to have known the flowers, may poſſibly be the male plant of our laſt-deſcribed ſpecies, bearing only one or two female flowers at the bottom of the ſtalks of the male catkins, according to the analogy obſerved in the foregoing ones. S.

GNIAFDA, in *Geography*, a town of Hungary; 7 miles W.S.W. of Palotza.

GNIDIA, in *Botany*, from *Gnidus*, where Venus had her temple. A ſeed, reported to be brought from thence, had been called *Coccognidium*, and there is a γνίδιον, or Κνίδιον, ſuppoſed to be a kind of Orache; but Linnæus probably had not theſe ſo much in view as the affinity of this genus to *Paſſerina*, named after a favourite bird of the goddeſs, in alluſion to which indeed it was firſt named *Struthia* by Van Royen. It is moreover akin to *Daphne*, one ſpecies of which, *Daphne Gnidium*, has been taken for the ancient γνίδιον.—Linn. Gen. 193. Schreb. 260. Willd. Sp. Pl. v. 2. 424. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 27. Juſſ. 77. Lamarck Illuſtr. t. 291.—Claſs and order, *Octandria Monogynia.* Nat. Ord. *Vepreculæ*, Linn. *Thymelææ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, funnel-ſhaped, coloured; its tube thread-ſhaped, very long; limb flat, in four deep ſegments. *Cor.* Petals four, ſeſſile, flat, inſerted into the edge of the tube of the calyx, and ſhorter than its limb. *Stam.* Filaments eight, briſtle-ſhaped, erect, inſerted into the tube in two rows, the uppermoſt reaching nearly to the top; anthers roundiſh, erect, ſimple, of two cells. *Piſt.* Germen ovate, ſuperior; ſtyle thread-ſhaped, as long as the tube, inſerted laterally into the germen; ſtigma capitate, hiſpid. *Peric.* a dry berry, with a thin coat. *Seed* ſolitary, ovate, obliquely pointed.

Eſſ. Ch. Calyx funnel-ſhaped, four-cleft, withering, including the ſtamens. Petals four, inſerted into the calyx. Style lateral. Seed coated.

Obſ. It differs from *Paſſerina* only in having petals; which are often rather of a glandular appearance. The habit is altogether that of *Daphne* and *Paſſerina.* Willdenow enumerates ſixteen ſpecies, but of theſe G. *pinifolia* and *radiata* are one and the ſame, and G. *daphnæfolia*, Linn. Suppl. 225, ſeems rather to belong to *Dais.*

All the genuine ſpecies are natives of the Cape of Good Hope, of a humble ſhrubby growth, with white or yellowiſh ſweet-ſcented flowers.

GNIEWE, or MEVE, in *Geography*, a town of Pruſſia, in the province of Pomerelia, on the Viſtula; 30 miles S.S.E. of Dantzic.

GNOIEN, a town of the duchy of Mecklenburg; 21 miles E.S.E. of Roſtock. N. lat. 53° 59′. E. long. 12° 52′.

GNOLL Rail-Way. This is an eſtabliſhment in Glamorganſhire, in South Wales, which we had not heard of at the time of compiling our article Canal; it is called an iron *waggon-way*, the flanch being on the wheels of the waggons, inſtead of being on the tram-plates, as is more common in that diſtrict. It commences at the ſhipping-place 200 yards below Neath bridge, on the Neath river; croſſes the Neath canal on a wooden bridge, and proceeds about E. half a mile to the late ſir Herbert Mackworth's Gnoll collieries, of run coals, which are drawn up forty fathom, to be loaded into the waggons on this waggon-way, which has ſo regular a deſcent, as to require no inclined planes, or other conſiderable works.

GNOMES, Gnomi, a name which the Cabbaliſts give to certain inviſible people, whom they ſuppoſe to inhabit the inner parts of the earth, and to fill it to the centre.

They are repreſented as very ſmall of ſtature, tractable, and friendly to men; and are made the guardians of mines, quarries, hidden treaſures, &c. Vigenere calls them Gnomons: the females of this ſpecies are called Gnomides.

Vigneul de Marville, in his Melange de Hiſtoire et de Literature, tome i. p. 100, gives a relation of a conference with a philoſopher of this claſs, who held, that an infinity of ſpirits inhabited each of the four elements, fire, air, water, and earth, under the denomination of *Salamanders*, *Sylphs*, *Oudins*, and *Gnomes;* that the Gnomes are employed in working or actuating the machines of brutes upon earth.

He added, that ſome philoſophers of that ſect held that theſe ſpirits were of two ſexes, for the two ſexes of beaſts or moving machines; that they were more or leſs perfect as the brutes were; and that there was an infinite number of exceedingly ſmall ones, to actuate the infinite number of inſects and animalcula, both thoſe that are viſible, and thoſe which are too ſmall to come under our ſenſes; that all theſe ſpirits, in general, govern their reſpective machines according to the diſpoſition of the parts or organs, the humours, temperaments, &c that they do not lay hold of all machines indifferently, but of thoſe ſuited to their own character, element, &c. that a haughty one, for inſtance, ſeizes a Spaniſh gennet; a cruel one a tyger, &c.

Gnome, Γνωμη, or *chria*, is alſo uſed for a ſhort, pithy, and ſententious obſervation, reflection, or the like, which is worthy to be treaſured up and remembered.

Such is that of Juvenal, "Orandum eſt, ut ſit mens ſana in corpore ſano." The writers of rhetoric diſtinguiſh ſeveral kinds of gnomes, according as they turn on words, on actions, or both; denominating them *verbal*, *active*, and *mixed gnomes* or *chriæ*. See Apophthegm.

GNOMON, in *Dialling*, is the ſtyle, pin, or cock of a dial, the ſhadow whereof pointeth out the hours.

The word is Greek, γνωμων, which literally imports ſomewhat that makes a thing known; becauſe the ſtyle or pin indicates or makes the hour, &c. known.

The gnomon of every dial is ſuppoſed to repreſent the axis of the world; and therefore the two ends or extremities thereof muſt directly anſwer to the north and ſouth poles. See Dial and Dialling.

Gnomon, in *Geometry*. If a parallelogram be divided into four leſſer ones, by two lines interſecting each other, and one of theſe parallelograms be retrenched or taken away, the other three will make a gnomon, ordinarily called a *ſquare*.

Or, a gnomon, in a parallelogram, may be ſaid to be a figure formed of the two complements, together with either of the parallelograms about the diameter. Thus, in the parallelogram A C, *Plate* VIII. *Geometry*, *fig*. 96, the gnomon is $M + x + z + N$; or $M + N + X + Z$.

Gnomon, in *Aſtronomy*, the name given to any upright pillar, when uſed for the purpoſe of determining the altitude of a celeſtial object, but particularly the ſun.

The extreme ſimplicity of this inſtrument renders it very probable, that it was the firſt ever uſed for aſtronomical purpoſes. It fortunately happened for the ſcience, that it was capable likewiſe of being a very exact one; and all the knowledge the ancients had of the ſolar theory ſeems to have been derived from this inſtrument. The principle of it is ſo ſimple, as hardly to require explanation. If the height of a vertical pillar be compared with its ſhadow on a horizontal plane, the altitude of the ſun may be deduced by trigonometrical calculation, ſince theſe two quantities are to each other, as the tangent to the radius, or as the ſine to the coſine of the altitude required. The ancient obeliſks found in Egypt and the Eaſt were probably inſtruments of this kind: it would be too much to conclude that every one was erected for aſtronomical purpoſes, but this was probably their original deſtination; and the figure of an obeliſk being rather pleaſing to the imagination, it was adopted as an ornament to public ſquares and buildings. As practical aſtronomy advanced to accuracy and perfection, however, the gnomon appeared to be ſubject to conſiderable defects. The ſhadow is found to be generally ill defined, ſo that its length cannot be very accurately meaſured; and to obviate this, the gnomon muſt be of greater height than is eaſily practicable. In modern Europe, therefore, the original gnomon has been almoſt entirely abandoned, and a new one ſubſtituted upon principles nearly ſimilar, but of a ſomewhat different conſtruction.

The gnomons of modern Italy are uſually conſtructed in very large edifices; a ſmall aperture is made in the upper part of the building, which permits a luminous circular image of the ſun to be formed on the pavement, on which a meridian line is accurately traced: a plumb line is ſuſpended from the aperture to the floor, and thus both the height of the aperture, and the diſtance of the ſolar image from the point immediately beneath it, is very accurately aſcertained.

There are upon record ſome very ancient obſervations made with inſtruments of this kind, particularly of Pythias, who obſerved the ſolſtices at Marſeilles above three centuries before the Chriſtian era. Pliny mentions an obeliſk erected by Auguſtus: this obeliſk was brought from Egypt, and was ſaid to have been made by Seſoſtris, near a thouſand years before Chriſt. It was uſed by Manlius for the ſame purpoſe for which it was originally deſtined, namely, to meaſure the height of the ſun.

The Chineſe have from the earlieſt time been in the conſtant practice of making uſe of a gnomon.

In the year 1278, a gnomon 40 feet high was erected at Pekin, by the Chineſe emperor Co-cheou King.

Ulugh Beigh, in the year 1437, obſerved the ſolſtices at Samarcand by the ſhadow of a gnomon 165 feet high: and ſimilar inſtruments are even ſaid to have been uſed by the ancient inhabitants of Peru.

The gnomons to which modern aſtronomy is the moſt indebted, are chiefly thoſe of France and Italy.

Paul Toſcanelli conſtructed a gnomon in the cathedral of Florence, whoſe height was 280 feet. Ximenes repaired this, and publiſhed an account of it in 1757.

Gaſſendi conſtructed a gnomon of 50 feet in the "College de l'Oratoire" at Marſeilles, and obſerved the ſolſtices with it in 1636.

Ignatius Dante, in 1575, a Dominican friar, and afterwards biſhop of Alatri, firſt conſtructed the celebrated gnomon in the church of St. Petronius, at Bologna: it was originally only about 70 feet high, but was raiſed by Caſſini, in 1653, to the height of 90 feet, and it was with this that his valuable ſolar obſervations were made.

Moſt of theſe gnomons are accompanied by a meridian line, often highly ornamented with the names of the months and ſigns of the zodiac, ſo as to ſerve the purpoſe of a calendar. One of the fineſt in Italy is in the Carthuſian convent at Rome, built on the ancient Thermæ of Diocletian. There are two, one to the north 62 feet, another on the ſouth 75 feet high: they were conſtructed by Bianchini in 1701.

Picard erected a gnomon in the royal obſervatory at Paris, which ſtill exiſts.

The meridian line in St. Sulpice, at Paris, was begun in 1727 by Sully, a watchmaker, and has ſince been much improved and highly ornamented: its height is 80 French feet.

M. de Ceſaris and Reggio in 1786, conſtructed a gnomon and meridian line in the cathedral at Milan: its height is 73 feet.

The reaſon why none of theſe gnomons are to be found in England, is that we do not regulate our clocks by ſolar, but by mean time: to this may be added our unfavourable climate, which would very much diminiſh the intereſt which they obtain in other countries, where they are made to ſerve the uſeful purpoſes of civil life.

Notwithſtanding the great attention that has been paid to the conſtruction of theſe gnomons, their uſe has been entirely ſuperſeded by modern inſtruments of ſmall dimenſions, ſo that to the aſtronomer they are now become merely objects of curioſity: yet to no inſtrument has aſtronomy greater obligation. The ſolar theory was firſt brought to a very improved ſtate by the uſe of this ſimple inſtrument alone. The length of the year, and the obliquity of the ecliptic, were determined by it with very great exactneſs. The ancient method of deducing the ſolar theory was nearly as follows.

To determine the obliquity of the ecliptic, the length of the ſhadows were obſerved at the period of the ſolſtices, and the extreme points to which the longeſt and ſhorteſt ſhadows extended at the moment of noon were carefully obſerved, and the altitudes of the ſun deduced at each of theſe periods: half the difference of the greateſt and leaſt altitudes would be the obliquity of the ecliptic, ſubject to a ſmall error ariſing from refraction, the effects of which were not known at that early period, nor were they very conſiderable in thoſe ſouthern portions of the globe in which aſtronomy had its origin. But though it was not difficult to deduce the length of the ſolſtitial ſhadows, it was by no means eaſy to determine the day on which either of the ſolſtices actually happened, becauſe the length of the ſhadow would appear to be the ſame at thoſe ſeaſons for ſeveral ſucceſſive days. It appears, by ſome very ancient Chineſe obſervations ſtill on record, that this inconvenience was remedied by obſerving the length of the ſhadow, ten or twenty days before the ſolſtice; then waiting till they found the meridian ſhadow again of the ſame length, they concluded that the moment of the ſolſtice happened on the intermediate day between theſe correſponding obſervations.

The length of the year was determined from obſervations of the equinoxes, which could be much more exactly obſerved; for the obliquity of the ecliptic being determined by the method above deſcribed, the length of the equinoctial was known, and the day on which the ſhadow correſponded to the computed ſhadow was evidently the day of the equinox.

It was by examining a ſucceſſion of theſe ſimple obſervations, that Hipparchus firſt diſcovered the great inequality, in the length of the four ſeaſons, ariſing from what is now called the equation of the orbit: and from the diſcovery of this important fact, we may date the origin of phyſical aſtronomy.

GNOMONIC COLUMN. See COLUMN.

GNOMONIC, *Polyhedron.* See POLYHEDRON.

GNOMONIC, or *Gnomonical projection*, that which repreſents the circles of a hemiſphere, upon a plain touching it in the vertex, by lines or rays from the centre of the hemiſphere to all the points of the circles to be projected.

In this projection, all the great circles of the ſphere are projected into right lines. Any leſſer circle parallel to the plane of projection is projected into a circle. And any leſſer circle not parallel to the plane of projection, is projected into a conic ſection.

The gnomonic projection is alſo called the "horologiographic projection," becauſe it is the foundation of dialling. In other reſpects it is not much uſed, becauſe the circles of the ſphere are projected into conic ſections, which are difficult to be deſcribed. However, this projection has its conveniences in the ſolution of ſome problems of the ſphere, on account of the great circles being all projected into right lines.

Mr. Emerſon, known by an ingenious Treatiſe upon Fluxions, and a variety of other publications, has given the theory and practice of the gnomonic projection, in his Treatiſe on the Projection of the Sphere, Lond. 1749, 8vo. See PROJECTION.

GNOMONICA, Γνωμονικη, or *Gnomonics*, the art of dialing, or of drawing ſun and moon-dials, &c. on any given plane.

It is thus called, as it ſhews how to find the hour of the day, &c. by the ſhadow of a gnomon or ſtyle.

GNOSIMACHI, in *Eccleſiaſtical Hiſtory*, an ancient ſect in religion, whoſe diſtinguiſhing character was, that they were profeſſed enemies of all ſtudied knowledge in divinity.

The word is *γνωσιμαχος*, *q. d.* an enemy of wiſdom or knowledge.

Damaſcenus ſays, that they were perfectly averſe from all the gnoſes of Chriſtianity, *i. e.* all the ſcience or technical knowledge thereof. They held it an uſeleſs labour to ſeek for gnoſes in the holy ſcriptures; and ſaid, that God requires nothing of men but good works; that it were, therefore, much better to walk with more ſimplicity, and not to be ſo ſolicitous about the dogmata of the gnoſtic life.

GNOSSUS, in *Ancient Geography*, a town of the iſland of Crete, more anciently called "Cœratus," from the name of the river which watered it. It was the fixed reſidence of Minos, once the capital of the iſland, and, according to Strabo, a wealthy and populous place, being 30 furlongs in compaſs, and full of inhabitants. This writer places it 20 furlongs from the Ægean or Archipelago, and 90 from the African ſea. Its port, called Heracleum, was at a conſiderable diſtance, according to Olivier about four or five leagues to the eaſtward. Pauſanias (Attic.) ſays, that it had a labyrinth. From this town Ariadne, ſo much celebrated by the poets, derived the name of Gnoſſis. When the iſland was reduced by the Romans, Gnoſſus was humbled, and Gortyna, her rival, raiſed upon her ruins. Sonnini ſays, that a ſmall village, Cnoſſou, near Candia, would recal to mind the ſcite of the ancient town, were it not diſcoverable, in a manner no leſs certain than afflicting, from the rubbiſh which covers it, and a great part of which has ſerved for the buildings of modern *Candia*, which ſee. See alſo Crete.

GNOSTICS, in *Eccleſiaſtical Hiſtory*, ancient heretics, famous from the firſt riſe of Chriſtianity, principally in the Eaſt.

It appears from ſeveral paſſages of the ſacred writings, particularly 1 John ii. 18. 1 Tim. vi. 20. and Col. ii. 8. that many perſons were infected with the Gnoſtic hereſy in the firſt century; though the ſect did not render itſelf conſpicuous, either for number or reputation, before the time of Adrian, when ſome writers erroneouſly date its riſe.

The word is formed of the Latin *gnoſticus*, and that of the Greek γνωϛικος, *knowing*, of γινωσκω, *I know*.

The name Gnoſtic was adopted by thoſe of this ſect, as if they were the only perſons who had the true knowledge of Chriſtianity. Accordingly they looked on all the Chriſtians as ſimple, ignorant, and barbarous perſons, who explained and interpreted the ſacred writings, in a too low, literal, and unedifying ſignification.

At firſt, the Gnoſtics were only the philoſophers and wits of thoſe times, who formed for themſelves a peculiar ſyſtem of theology, agreeable to the philoſophy of Pythagoras and Plato; to which they accommodated all their interpretations of ſcripture. Theſe enthuſiaſtic and ſelf-ſufficient philoſophers boaſted of their being able to reſtore mankind to the knowledge (*gnoſis*) of the true and Supreme Being which had been loſt in the world. They alſo foretold the approaching defeat of the *evil principle*, to whom they attributed the creation of this globe, and declared, in the moſt pompous terms, the deſtruction of his aſſociates, and the ruin of his empire. But

Gnostics afterwards became a generical name, comprehending divers ſects and parties of heretics, who roſe in the firſt centuries, and who, though they differed among themſelves as to circumſtances, yet all agreed in ſome common principles. They were ſuch as corrupted the doctrine of the goſpel by a profane mixture of the tenets of the oriental philoſophy, concerning the origin of evil and the creation of the world, with its divine truths.

It was one of the chief tenets of the philoſophy of the Chriſtian Gnoſtics, that rational ſouls were impriſoned in corrupt matter, contrary to the will of the Supreme Deity. In conformity to the opinion of the oriental ſages, who expected an extraordinary meſſenger from the Moſt High, endowed with wiſdom and inveſted with authority to communicate to miſerable mortals juſt notions of the Supreme Being, and to deliver them from the chains of the tyrants and uſurpers of this world, they believed, when Chriſt appeared and wrought miracles of the moſt aſtoniſhing and ſalutary kind, that he was the expected and wiſhed-for meſſenger. Accordingly they imagined that he would reſcue men from the power of the malignant genii, or ſpirits, to which, agreeably to their doctrine, the world was ſubjected, and ſo free their ſouls from the dominion of corrupt matter. Having admitted this ſuppoſition, they interpreted, or rather corrupted, all the precepts and doctrines of Chriſt and his apoſtles, in ſuch a manner as to reconcile them with their own erroneous tenets.

Such were the Valentinians, Simonians, Carpocratians, Nicolaitans, &c.

Gnostics, a denomination ſometimes alſo more particularly attributed to the ſucceſſors of the firſt Nicolaitans and Carpocratians, in the ſecond century, upon their laying aſide the names of the firſt authors. Such as would be thoroughly acquainted with all their doctrines, reveries, and viſions, may conſult St. Irenæus, Tertullian, Clemens Alexandrinus, Origen, and St. Epiphanius; particularly the firſt of theſe writers, who relates their ſentiments at large, and confutes them at the ſame time: indeed, he dwells more expreſsly on the Valentinians than any other ſort of Gnoſtics; but he ſhews the general principles whereon all their miſtaken opinions were founded, and the method they followed in explaining ſcripture. He accuſes them with introducing into religion certain vain and ridiculous genealogies, *i. e.* a kind of divine proceſſions or emanations, which had no other foundation but in their own wild imagination.

In effect, the Gnoſtics confeſſed, that theſe æons or emanations were no where expreſsly delivered in the ſacred writings; but inſiſted, at the ſame time, that Jeſus Chriſt had intimated them in parables to ſuch as could underſtand him. They built their theology not only on the goſpels and the epiſtles of St. Paul, but alſo on the law of Moſes and the prophets.

Theſe laſt laws were peculiarly ſerviceable to them, on account of the allegories and alluſions with which they abound; which are capable of different interpretations.

However, their doctrine, concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Teſtament, which contradicted this idle fiction, and filled them with an abhorrence of Moſes and the religion he taught; alleging, that he was actuated by the malignant author of this world, who conſulted his own glory and authority, and not the real advantage of men. Their perſuaſion that evil reſided in matter, as its centre and ſource, made them treat the body with contempt, diſcourage marriage, and reject the doctrine of the reſurrection of the body and its re-union with the immortal ſpirit. Their notion, that malevolent genii preſided in nature, and occaſioned diſeaſes and calamities, wars and deſolations, induced them to apply themſelves to the ſtudy of magic, in order to weaken the powers or ſuſpend the influence of theſe malignant agents.

The Gnoſtics conſidered Jeſus Chriſt as the Son of God, and, conſequently, inferior to the Father, who came into the world for the reſcue and happineſs of miſerable mortals, oppreſſed by matter and evil beings: but they rejected our Lord's humanity, on the principle that every thing corporeal is eſſentially and intrinſically evil; and, therefore, the greateſt part of them denied the reality of his ſufferings. They ſet a great value on the beginning of the goſpel of St. John, where they fancied they ſaw a great deal of their æons or emanations under the *Word*, the *Life*, the *Light*, &c. They divided all nature into three kinds of beings, *viz. hylic*, or material; *pſychic*, or animal; and *pneumatic*, or ſpiritual.

On the like principle they alſo diſtinguiſhed three ſorts of men; *material*, *animal*, and *ſpiritual*. The firſt, who were material, and incapable of knowledge, inevitably periſhed, both ſoul and body; the third, ſuch as the Gnoſtics themſelves pretended to be, were all certainly ſaved; the pſychic, or animal, who were the middle between the other two, were capable either of being ſaved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greateſt part of this ſect adopted very auſtere rules of life, recommended rigorous abſtinence, and preſcribed ſevere bodily mortifications, with a view of purifying and exalting the mind. However, ſome maintained, that there was no moral difference in human actions; and thus, confounding right with wrong, they gave a looſe rein to all the paſſions, and aſſerted the innocence of following blindly all their motions, and of living by their tumultuous dictates. They ſupported their opinions and practice by various authorities: ſome referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaſter, Chriſt, and his apoſtles; others boaſted that they had deduced their ſentiments from ſecret doctrines of Chriſt, concealed from the vulgar; others affirmed, that they arrived at ſuperior degrees of wiſdom by an innate vigour of mind; and others aſſerted, that they were inſtructed in theſe myſterious parts of theological ſcience by Theudas, a diſciple of St. Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient Gnoſtics were revived in Spain, in the fourth century, by a ſect called the *Priſcillianiſts.* (See Moſheim's Eccl. Hiſt. vol. i.)

The appellation Gnoſtic ſometimes alſo occurs in a good ſenſe, in the ancient eccleſiaſtical writers, and particularly in Clemens Alexandrinus, who, in the perſon of his Gnoſtic, deſcribes the characters and qualities of a perfect Chriſtian. This point he labours in the ſeventh book of his Stromata, where he ſhews, that none but the Gnoſtic, or learned perſon, has any true religion. He affirms, that were it poſſible for a knowledge of God to be ſeparated from eternal ſalvation, the Gnoſtic would make no ſcruple to chooſe the knowledge; and that if God would promiſe him impunity in doing of any thing he has once ſpoken againſt, or offer him heaven on thoſe terms, he would never alter a whit of his meaſures.

In this ſenſe the father uſes Gnoſtics, in oppoſition to the heretics of the ſame name; affirming, that the true Gnoſtic is grown old in the ſtudy of the holy ſcripture; and that he preſerves the orthodox doctrine of the apoſtles, and of the church; whereas the falſe Gnoſtic abandons all the apoſtolical traditions, as imagining himſelf wiſer than the apoſtles.

At length the name Gnoſtic, which originally was the moſt glorious, became infamous, by the idle opinions and diſſolute lives of the perſons who bore it; much as, in the preſent age, it has fared with the name *quietiſt*, *pietiſt*, &c.

GNU, in *Zoology*, a ſpecies of Antelope, having horns thick, rough, and bent much forwards at the baſe, then ſuddenly turned backwards, a ferruginous body, a neck with a mane, and a tail whitiſh. This animal inhabits the country of the great Namaquas, to the north of the Cape of Good Hope. It feeds in large flocks in the plains: is exceedingly fierce, very ſwift, and fights with its horns; it frequently drops on its knees, runs quickly in that poſture, furrowing the ground with its horns and legs. It is a ſingular animal, having the body like a horſe, with a thick bull-like head, elegant taper legs like a deer, and the lachrymal furrows of the Antelope tribe. It is about 6½ feet long, and 3½ high at the ſhoulders; of a ruſty brown colour, having its hair tipt with white, but on the breaſt and fore-legs long and black; the head is large and clumſy, with a ſquare mouth and broad flaps over its noſtrils; on the chin and gullet is a long hanging beard, or bunch of white hairs; the neck is ſhort, thick, and ſomewhat arched, with an erect aſh-coloured mane; the tail is long, white, and flowing like that of a horſe; the feet have only one ſpurious hoof on each. The fleſh is reckoned very good.

GO is ſometimes uſed in *Law*, in a ſpecial ſignification. Thus, to *go without day*, and to *go to God*, denote as much as to be diſmiſſed the court, and to be acquitted.

GOA, in *Geography*, an iſland in the Eaſt Indian ſea, near the weſt coaſt of Hindooſtan, ſeparated from the continent by a river called "Mandova;" about eight leagues in circumference. The ſoil, eſpecially in the vallies, is fertile; the trees are always covered with leaves, flowers, and fruit; and ſprings in abundance iſſue from the mountains. The rainy ſeaſon continues here from June till September or October; and the land-floods bring down ſuch quantities of mud and ſand as ſtop up the haven and impede the navigation. In the months of April and May the weather is ſultry, but from October to March it is very moderate.

Goa, a city and capital of the Portugueſe ſettlements in India, the ſeat of a viceroy, and ſee of an archbiſhop, taken by the Portugueſe general Albuberque in 1510 from a prince of Saracen extraction. The port of Goa is naturally, and ſtill more by the improvements of the Portugueſe, one of the beſt in India; it is fortified with many caſtles and towers, and furniſhed with abundance of good cannon. Beyond theſe caſtles the channel becomes narrow, ſtraitening ſometimes to one, ſometimes to two miles, and its banks are planted with the beſt fruits and fineſt trees which India affords. Eight miles up the channel is the town of Goa. About the middle of this diſtance is a palace, now ſerving as a barrack for the garriſon; and here begins a ſtrong broad wall, two miles in length, which is a foot-walk when the country is overflowed, and in the vicinity of it a great quantity of ſalt is collected. This channel, which forms ſo excellent a port, runs many miles into the country, dividing it into ſeveral fruitful iſlands and peninſulas, which plentifully furniſh the city with neceſſaries. Adjoining to this port is the haven of Murmugon, formed by the other channel, that runs between the iſland of Goa and peninſula of Salſete, and affords a ſafe retreat to the Portugueſe and other ſhips, when they are ſhut out of the port by the ſands which are brought down by the river Mandova, in conſequence of the firſt rains of June, and till the paſſage is opened in October. This port of Murmugon is defended by a caſtle on the iſland of Salſete, and a good garriſon. At the ſouth entrance into the channel are the ruins of Old Goa; and from thence to the new city is a commodious road, elegantly adorned with trees for fruit and ſhade. The walls of the new city, which is decaying, include a ſpace of 12 miles in circuit; and the public ſtructures that remain ſufficiently evince its former grandeur as well as extent. The number of inhabitants is ſaid to be about 20,000; they conſiſt of native Portugueſe, Meſtizos, and Canarians, or natives, who are black as jet, with long black hair, and fine features; here are alſo many negro ſlaves, and Pagans of different nations. As to the character of the inhabitants, the men are ſaid to be, for the moſt part, proud, indolent, jealous, revengeful, and indigent; the women lazy, laſcivious, and as well ſkilled in poiſoning as any in the world;—215 miles S.S.E. from Bombay. The inquiſition, formerly exiſting in this place, is now aboliſhed. N. lat. 15° 28 20″. E. long. 73° 45′ 45″.

Goa, or *Goach*, a kingdom on the weſt and ſouth-weſt coaſt of the iſland of Celebes, which, after various conflicts and revolutions, is now dependent on the kingdom of Boni. The capital of the ſame name ſtands on a little iſland, on the banks of a river, whence the kingdom derives its denomination. It was built about the ſame period as Samboupo and Tello; and was taken by the Dutch in 1778. S. lat. 5 12′. E. long. 119° 51′.

GOACHO, a town of Peru, in the dioceſe of Lima, near the Pacific ocean; 65 miles N.N.W. of Lima. S. lat. 11 .

GOAD, in *Rural Economy*, a term applied to a pointed inſtrument, by which oxen are driven when employed in team-labour. It has frequently, likewiſe, a leather thong attached to the contrary end of it, ſo as to form a ſort of whip.

GOAFFI, in *Geography*, a town of Africa, in the kingdom of Mandinga, on the Senegal.

GOAHIROS, a nation of South America, ſituated between the juriſdiction of Maracaibo and the Rio, or river de la Hache: they occupy the coaſt for more than 30 leagues, and extend equally far into the interior part of the country. They have at all times been conſidered as the moſt ferocious of the maritime Indians. The Spaniards never even attempted to conquer them. Some miſſionaries have made efforts for inſtructing and proſelyting them to the Chriſtian faith, but without any permanent effect. Their number amounts to 30,000. They are governed by a cazique, for whom they have erected a citadel upon a ſmall eminence, called "La Teta," the Pap; at the diſtance of ſome leagues from the ſea. They breed horſes upon which they ride with incredible rapidity. Their troops are all mounted, each ſoldier carrying a carabine, cartridge-box, bow and quiver. They experience much friendſhip from the Engliſh of Jamaica. They aſſiſt them with advice, and ſupply them with arms. Theſe marauders have rarely any communication with Maracaibo, becauſe, as its juriſdiction is the principal ſcene of their robberies and atrocities, the inhabitants are obliged to be continually on their guard, ſo as to be always ready to repel the aggreſſions of ſuch troubleſome neighbours. The Spaniſh city to which they chiefly reſort is Rio-de-la-Hache, depending upon the vice-royalty of Santa Fé, where they barter their commodities. They ſet out in bands, moſt commonly preceded by their wives, who carry their children upon their backs, beſides other loads, too heavy even for beaſts of burden. Dreading impoſition, they have never adopted the uſe of ſpecie, but barter their horſes and oxen chiefly for ſpirituous liquors, to the uſe of which they are much addicted. Urged by their neceſſities they recur to arms, and threaten the neareſt city or village. After ſome hoſtilities, the Spaniards ſue for peace, and obtain it in conſideration of ſome pipes of brandy and other ſmaller articles. Although theſe Indians are well received in the Spaniſh cities, they will not admit any Spaniard into their country; and yet ſome Spaniſh ſmugglers contrive, for pecuniary conſiderations, to obtain a paſſport and eſcort for traverſing the country of the Goahiros, and they have thus acquired many partizans among the Spaniards themſelves; but their principal and moſt uſeful connection is formed with the Engliſh of Jamaica. By them they are ſupplied, not only with arms and ammunition, but with the ſtuffs that clothe them. Their dreſs is ornamented by a great variety of feathers, fragments of ſhining metals, and gold ridiculouſly fixed to their ears, noſe, and arms. The articles with which they furniſh the Engliſh in exchange for the merchandize they receive are pearls, which they fiſh in their own ports, and horſes, mules, and oxen. Their ferocity is ſuch, that even the Engliſh will ſeldom ſo far confide in them as to venture on ſhore, but the buſineſs of bartering is tranſacted on board, and the ſhips haſten to depart. The ſhips that are accidentally caſt upon the coaſt, immediately become the prey of theſe cannibals, who maſſacre the crew and devour their fleſh; dividing the cargo among thoſe who are preſent on the occaſion. The Goahiros are ſaid to be a formidable nation, well mounted, armed, and diſciplined; and able to bring into the field 40,000 effective men.

On the eaſtern part of the territory of the Goahiros are the "Cocinas" Indians, who live like ſavages, but are ſo cowardly and puſillanimous as to allow the Goahiros to exerciſe an authority, which the bold always acquire over the timid. Theſe ſavages are, in fact, merely the ſlaves of other ſavages. Depons's travels, vol. i.

GOAL. See GAOL.

GOAL-PARAH, in *Geography*, a town of Hindooſtan, in Bengal, ſituated on the Burhampooter, and on the borders of Aſſam; where the Europeans have factors, who carry on a conſiderable trade with Aſſam, Bootan, Thibet, &c.; 32 miles E. of Rangamatty.

GOAN, the name of a Perſian tree, of the aſhes of which they make a ſort of antiſpodon, or medicinal powder, for diſeaſes of the eyes.

GOANAGOODY, in *Geography*, a town of Hindooſtan, in Marawar; 8 miles E. of Tripalore.

GOANDA, a naked, ſavage and ferocious race, who inhabited the extenſive and unexplored wilderneſs, E. of Nagpour, in Hindooſtan, which is pervaded by the great river Bain, or Baun Gonga, and terminates in the mountains bounding the Engliſh circars.

GOAR, ST. a town of France, in the department of the Rhine and Moſelle, and chief place of a canton, in the diſtrict of Simmern, ſituated on the weſt ſide of the Rhine, in which there is, near this place, a water-fall; 16 miles S. of Coblentz. N. lat. 50° 8′. E. long. 7° 43′.

GOAR-*Vetch*, a name ſometimes applied to the ſummer vetch. See TARE and VETCH.

GOARING, on *Ship-board*. The ſeamen ſay a ſail is cut *goaring*, when it is cut ſloping by degrees, and is broader at the clew than at the ear-ring, as all top-ſails and top-gallant-ſails are.

GOAS, in *Geography*, a town of Bengal; 11 miles E. of Moorſhedabad.

GOAT, in *Zoology*. See CAPRA.

GOAT, in *Rural Economy*, is an animal, that in particular ſituations may be kept with advantage by the farmer, as where the country is rocky and barren, and there is but little keep for any other ſort of animal. The goat is capable of climbing the ſteepeſt rocks, and of browſing upon the briers, heath, and ſhrubs of ſeveral different kinds, which are rejected by other ſorts of animals. When turned into paſture grounds they ſhould conſequently be prevented from nipping the young ſhoots of trees and other woods, as they prefer them to the graſs.

They are beneficial in ſeveral different points of view, as in their milk, which they afford plentifully, and which is of a very excellent quality. In ſome caſes, this and cow's milk are mixed together, and a highly valuable cheeſe prepared from them.

The young kids are likewiſe very excellent food, and two or three are frequently brought forth at a time, often twice in the courſe of the year.

The hair of the goat is alſo very valuable for different purpoſes, as the making of ropes to be uſed in the water, which are extremely durable. A ſort of ſtuff is alſo formed from it in ſome places. It may be ſheared in the ſame manner as wool from the ſheep.

The ſuet of the goat is excellent, the animals being in ſome places, as in Caernarvonſhire, killed merely for the object of their ſuet; which is capable of being made into candles of a ſuperior quality to thoſe of the common kind.

Their horns conſtitute valuable handles for tucks and pen-knives. The ſkin of the young kid is well ſuited to the glove manufactory, from its taking on a dye better than any other ſort of ſkin. The old ſkin is highly uſeful alſo, being in many caſes preferred to that of the ſheep; beſides, the fleſh affords a cheap and abundant food for the winter months, eſpecially when the kids have been ſent early to market. The haunches of the goat are often ſalted and dried, and ſupply all the uſes of bacon; and are known by the Welch under the name *coch yr wden*, or hung veniſon.

In chooſing goats for keeping, the following directions ſhould be attended to. The male ſhould have a large body, with long hair, and ſtraight ſtiff legs, the neck ſhould be plain and ſhort, the head ſmall and ſlender, the horns large, the eyes prominent, and the beard long.

The female ought to have a large udder with well ſized teats, and with none or very ſmall horns.

Goats are beſt kept in flocks, in order that they may have the leſs diſpoſition to ſtraggle; and they ſhould have good ſhelter both for ſummer and winter, great heat and cold being equally injurious to them.

The period of coupling them is about December.

They are moſtly kept without litter in the winter ſeaſon, in clean paved yards or other places.

The kids may be prepared for the table in a manner ſimilar in ſome degree to that of the lamb.

They have been vulgarly ſuppoſed uſeful in ſtables from the diſagreeable odour that iſſues from the males at particular ſeaſons, but there are probably no real grounds for ſuch a concluſion.

GOAT-*fiſh*, *Capriſcus*, in *Ichthyography*, the name of a fiſh, called alſo by ſome *caper*. It is a ſpecies of BALLISTES. In the middle of its back it has three very ſtrong and large prickles, the firſt of which is three times as large as any of the others, and all are connected by a membrane.

The whole fiſh is covered with a ſcaly ſkin; but the ſcales have more the appearance of thoſe of a ſerpent than thoſe of the fiſh; for they are placed in cancellated lines interſecting one another, and are ſo well fixed, that they with difficulty come off; and wood or ivory may be poliſhed with the ſkin, as with the common fiſh-ſkin uſed by the turners, &c. It is of a blueiſh-green colour, ſpotted with a fine blue, and the back and belly fins are black, with ſome blue and red ſpots. Its whole figure is very broad and flat, as well as ſhort, ſo that it approaches to a round form. It ſeldom exceeds two pounds in weight. It is caught in the Mediterranean, but not commonly. The ſkin of it is frequently found in the cabinets of the curious.

GOAT *Iſlands*, in *Geography*, two ſmall iſlands near the S. coaſt of Jamaica, they are denominated *Great* and *Little*; the former is ſituated in N. lat. 17° 53'. E. long. 76° 51'; and the latter about a mile N. W. from it.

GOAT *Iſland*, the ſouthernmoſt of the Baſhee iſlands, in the Eaſt Indian ſea. N. lat. 20° 6'. E. long. 121°.—Alſo, a ſmall iſland among the Philippines, near the S. W. coaſt of Luçon. N. lat. 13° 52'. E. long. 120° 13'.—Alſo, a ſmall iſlot of America, in the ſtate of Rhode iſland, oppoſite to the town of Newport, and on which is Fort Waſhington.

GOAT's *Beard*, in *Botany*. See TRAGOPOGON.

GOAT's *Eye*, in *Surgery*. See EYE.

GOAT's *Horns, petrified*. In Dr. Grew's "Rarities of Greſham College," p. 257, a Tephrites bœtii, or goat's horn, in that collection, is deſcribed as broken at both ends, about ſix inches long, and 2½ inches acroſs at the broadeſt part, the belly an inch over and furrowed, the back ſomewhat edged, of an aſhen colour, inwardly blueiſh grey, outwardly mixed with oblique and white ſtreaks, bended, one end thicker than the other: it is added, that ſuch are found in Germany, Moravia, Sileſia and other parts, and efferveſce with nitric acid.

In the Analyſis of the Labours of the French national Inſtitute for 1809, it is mentioned that M. Cuvier in the alluvial ſoils near Etampes had diſcovered horns, ſome of which do not ſeem to differ eſſentially from the horns of the exiſting ſpecies of goats. The evidence in neither of the above caſes, or any other which we have ſeen, is ſufficiently ſtrong to prove the foſſil horns of this claſs to have really belonged to goats: and analogy would juſtify us rather, in referring them to the extinct race of animals, fiſh, and vegetables with which the ſtrata are ſo abundantly ſtored, in ſome parts of the ſeries.

GOAT's *Rue*. See GALEGA.

GOAT, *Scape*. See SCAPE-GOAT.

GOAT's *Sucker*. See CAPRIMULGUS.

GOAT's *Stones, greater*. See SATYRIUM.

GOAT's *Stones, leſſer*. See ORCHIS.

GOAT's *Thorn*. See ASTRAGALUS.

GOATFIELD, in *Geography*, a mountain of Scotland, in the iſland of Arran; the ſummit of which is 2840 feet above the level of the ſea.

GOAVE, GRAND, a town of the iſland of Hiſpaniola; 10 miles S.W. of Leogane.

GOAVE, *Petit*, a ſea-port town of the iſland of Hiſpaniola, with a harbour capable of receiving veſſels of the largeſt ſize ſafe from winds; in its environs are plantations of ſugar, coffee, indigo, and cotton. The town is the emporium to which the inhabitants of Grand Goave, and other places, ſend their commodities; 20 miles W.S.W. of Leogane. N. lat. 18° 26'. W. long. 73° 37'.

GOBAN, a town of Perſia, in the province of Chuſiſtan; 75 miles S. of Suſter.

GOBAN, or *Geban*, a ſmall iſland in the mouth of the Euphrates, or Shat el Arab, at the entrance into the gulf of Perſia, with a town upon it; 50 miles E.S.E. of Baſſora. N. lat. 30° 10'. E. long. 48° 25'.

GOBANNIUM, in *Ancient Geography*, a town of Britain, placed in Antonine's Itinerary between Burrium or Uſk, and Magnis or Kencheſter, 12 miles from the former and 22 from the latter, and ſuppoſed to be Abergavenny, which ſee.

GOBBI, in *Geography*, a country of Africa, between that of Camma, and cape Lopez Gonſalvo; the chief trade of which conſiſts in elephants and ivory. The chief town is about a day's journey diſtant from the Atlantic. N. lat. 1° 30'. See CAMMA.

GOBBINS, in *Mining*, is a name with the colliers of ſeveral diſtricts for the hole-ing ſtuff and other refuſe of their works; as alſo for the hollows or ſpaces behind them, into which they throw the refuſe coal, earth, and ſtones: which laſt are alſo called waſtes and old-hollows.

In the coal-pits about Wedneſbury in Staffordſhire, and at Doniſthorp, Danby-Hall, &c. in Derbyſhire, the gobbins take fire ſpontaneouſly after ſome time, unleſs the air is excluded from them, owing to duns, tow, tawe or catdirt, a thin ſtratum found near the coal, which heats, ſwells, and ſpontaneouſly inflames, by the contact of air and moiſture. At Doniſthorp they encaſe their gobbins in walls of tempered clay at certain diſtances, for excluding the air.

GOBBS, otherwiſe *Cobbles*, are pieces of coal from the ſize of walnuts to that of a man's fiſt or larger, which are occaſionally picked or raked out of the ſleck or refuſe ſmall coals at the collieries, either by poor perſons, who are allowed to do ſo, or for ſale. Theſe are what in London, and many places in the eaſt and ſouth of England, would be called round-coals and highly valued, on account of the abſence of very ſmall or duſt coals among them. Where the rage among the buyers and dealers is for *large coals*, as about Wedneſbury in Staffordſhire, and the Erewaſh vale in Derbyſhire and Nottinghamſhire, an inconceivable waſte is made of cobbles and ſleck; in working the thick coal about Wedneſbury a heap of ſuch, ſix or ſeven yards thick, is ſaid to be left and waſted on the floor of their works:

and to occaſion a further waſte of a rib or wall of ſolid coal, round each ſtall or chamber, for excluding the air, which would otherwiſe fire theſe waſte heaps. See Gobbins.

GOBELINS, a celebrated manufactory, eſtabliſhed at Paris, in the Fauxbourg St. Marcel, for the making of tapeſtry, and other furniture for the uſe of the crown. The houſe where this manufactory is carried on was built by two brothers, Giles and John Gobelins, both excellent dyers; and the firſt that brought to Paris, in the reign of Francis I. the ſecret of dyeing that beautiful ſcarlet colour ſtill known by their name; as well as the little river Bievre, on whoſe banks they fixed their dye-houſe; and which is now known by no other name than that of the river of the Gobelins.

It was in the year 1667 that this place, till then called "Gobelins' Folly," changed its name into that of "Hotel Royal des Gobelins," in conſequence of an edict of Louis XIV. Monſ. Colbert having re-eſtabliſhed, and with new magnificence enriched and completed the king's palaces, particularly the Louvre and Thuilleries, began to think of making furniture ſuitable to the grandeur of thoſe buildings: with this view he called together all the ableſt workmen in the divers arts and manufactures throughout the kingdom; particularly painters, tapeſtry-makers, ſculptors, goldſmiths, eboniſts, &c. and by ſplendid offers, penſions, privileges, &c. called others from foreign nations.

And to render the intended eſtabliſhment firm and laſting, he brought the king to purchaſe the Gobelins, for them to work in, and draw up a ſyſtem of laws, or policy, in ſeventeen articles.

By theſe it is provided, that the new manufactory ſhall be under the adminiſtration of the ſuperintendant of the king's buildings, arts, &c. that the ordinary maſters thereof ſhall take cognizance of all actions and proceſſes brought againſt any of the perſons in the ſaid manufactory, their ſervants and dependants; that no other tapeſtry work ſhall be imported from any other country, &c.

The Gobelins has ever ſince remained the firſt manufactory of this kind in the world. The quantity of the fineſt and nobleſt works that have been produced by it, and the number of the beſt workmen bred up therein, are incredible; and the preſent flouriſhing condition of the arts and manufactures of France is, in a great meaſure, owing thereto.

Tapeſtry work, in particular, is their glory. During the ſuperintendance of M. Colbert, and his ſucceſſor M. de Louvois, the making of tapeſtry is ſaid to have been practiſed to a degree of perfection, ſcarce inferior to what was before done by the Engliſh and French.

The battles of Alexander, the four ſeaſons, four elements, the king's palaces, and a ſeries of the principal actions of the life of Louis XIV. from the time of his marriage to the firſt conqueſt of Franche Comté, done from the deſigns of M. Le Brun, director of the manufactory of the Gobelins, are maſter-pieces in their kind.

GOBEMOUCH, the *fly-catcher lizard*, a ſpecies of American lizard that is always employed in catching of flies. It is the ſmalleſt of all the lizard kind, and is very beautiful, its ſkin often appearing as if covered with leaf-gold, or leaf-ſilver, and in ſome others of a green, or red and gold, wonderfully bright and beautiful. They are not at all ſhy or fearful of men, but as they do not hurt, ſo they ſeem to dread none; they enter chambers and cloſets, and do no ſort of damage, but deſtroy the flies and other troubleſome vermin they find there. Their whole lives ſeem ſpent in the chace of theſe inſects, and it is a very pleaſing thing to obſerve the various ways they have of catching them. They are very cleanly creatures, and may be ſuffered to run over the table at meal time; where, if they ſee a fly, they will purſue it over the very hands or cloaths of people, or over the diſhes, without doing the leaſt hurt.

Notwithſtanding their great beauty while alive, they are only of a duſky grey when dead, all their other colours immediately vaniſhing.

GOBE-MOUCHE, in *Ornithology*, a name given by Buffon to ſeveral ſpecies of *Lanius*, *Todus*, *Turdus*, *Muſcicapa*, and *Motacilla*, which ſee reſpectively.

GOBIN, St., in *Geography*, a town of France, in the department of the Aiſne; celebrated for its manufacture of plate-glaſs; 4 miles S. of la Fere. See Glass.

GOBIO, in *Ichthyology*, a ſpecies of *Cottus*; and alſo of *Cyprinus*; which ſee reſpectively.

GOBIUS, a genus of the thoracic order, poſſeſſing, according to Linnæus, the following eſſential character. Head ſmall, eyes approximated, with two punctures between; gill-membrane four-rayed; body ſmall, compreſſed on each ſide, covered with ſmall ſcales, and furniſhed with a ſmall tubercle behind the vent; the ventral fins united into an oval or funnel ſhape; and the dorſal fins two in number.

At the time Linnæus wrote his Syſtema Naturæ, the above character was probably found ſufficiently explicit to embrace, in a correct and lucid order, all the ſpecies of this natural tribe of fiſhes at that period known. This, however, it muſt be confeſſed, is not preciſely the caſe at preſent. The number of ſpecies has been materially augmented by the recent diſcoveries of naturaliſts, and among theſe are certain kinds which exhibit differences eſſentially diſſimilar from each other; though ſtill, in the idea of the Linnæan ſtudent, they can be only referable to the genus Gobius; while others, no leſs intimately allied, cannot, without a palpable innovation on the order of nature, be configued to that genus. The later French writers, as Latreille, Boſc and others, after the example of Lacépede, divide the Linnæan Gobii, and their natural affinities, into four diſtinct genera, namely, Gobius, Gobioides, Gobiomorus, and Gobiomoroides, an extenſion perhaps requiſite, or at leaſt admiſſible. This extenſion is indeed, in our own opinion, rather deſirable, and we refrain from adopting it only to avoid that degree of perplexity which might probably reſult from the diſperſion of the ſpecies into the ſeveral diſtinct articles, which would then become neceſſary. For this reaſon, we propoſe to concentrate the whole in one point of view, obſerving only to refer the ſpecies reſpectively to their different genera as we proceed, and by this means leave it to the judgment of the reader, whether thoſe recently eſtabliſhed genera ought to be in reality conſidered eſſentially diſtinct, or as only conſtituting the natural ſubdiviſions of the Linnæan genus Gobius.

The habits of theſe fiſhes in general appear to correſpond; they are chiefly inhabitants of waters contiguous to the ſhores, and lie concealed among the rocks, under ſtones, or in the ſand and mud of ſeas and rivers: they feed on worms, inſects, and the ſpawn and fry of fiſhes; and adhere firmly to the rocks or other hard ſubſtances by means of their ventral fins.

Species.

Genus *Gobius* —*Ventral fins united; dorſal fins two.*

† Section. *Pectoral fins attached cloſe to the body.*

Boddaerti. Rays of the anterior dorſal fin cirriform, the third very long. Pallas.

A native of the Indian ſeas, in common about ſix inches in length, and never exceeding eleven or twelve inches. The head thick, blunt, and ſomewhat convex, with ſpots of brown and white; crown convex, and gradually ſloping down; jaws of nearly equal length; lips thick and fleſhy; eyes vertical and oblong; gill-membrane livid. The body is rather convex, tapering ſlightly towards the tail, and covered with ſmall and ſoft ſcales; the colour blueiſh brown above, beneath pale yellow, inclining to whitiſh; the back marked with a longitudinal ſeries of ſeven brown ſpots, beneath which, on the ſides, are ſeven other ſpots of the ſame colour, but theſe latter are ſpeckled with white; the vent, which is ſituated rather nearer the head, is ſurrounded by a black circle, behind which is a conic peduncle. The dorſal fins are blueiſh black, the firſt including five rays, has the membrane ſpotted with white; the membrane of the ſecond is remarkable in having ſix white lines between each ray, theſe rays are ſetaceous, and amount to twenty-five in number; the pectoral fin is roundiſh, and includes twenty-one rays; ventral, thirty-four; anal, twenty-five; and the tail, which is blueiſh white, eighteen rays.

LAGOCEPHALUS. Upper jaw hemiſpherical; no tongue and lateral line. Pallas.

The native place of this ſpecies is uncertain; it was firſt deſcribed by Kolreuter, in the Tranſactions of the Royal Academy of Peterſburgh, and afterwards by Pallas in his "Spicilegia Zoologica." The head is ſhort, thick, and deſtitute of ſcales, the mouth tranſverſe; eyes diſtant, ſmall, and covered with a common ſkin; upper jaw very thick, the lower with a few larger teeth, which are a little hooked; the lips cleft in the middle, doubled, the upper fleſhy and very thick, and alſo reaching much beyond the jaw; palate with numerous crowded teeth of ſmall ſize on the margin. The body round, compreſſed towards the tail, of a grey or brown colour, and covered with minute ſcales; vent in the middle of the body. The firſt dorſal fin contains ſix rays of a ſimple form, the rays in the ſecond fin, like thoſe of the tail, are branched, and amount in number to eleven; the pectoral fin lanceolate oval, with fifteen rays; ventral, with eight ſhort crowded rays; anal, ten rays; and caudal, twelve. The total length of this fiſh about three or four inches.

CYPRINOIDES. Body covered with large ſub-ciliated ſcales; tail rounded; the membrane connecting the rays teſſellate with brown. Pallas.

About the ſize of a finger, the body of a compreſſed form, thickiſh, convex, grey brown above, beneath whitiſh; ſkin ſoft and cancellated with fine lines; teeth minute and nearly equal; tongue flat, ſoft, and obtuſe; eyes lateral and between them a blackiſh ſemi-lanceolate creſt; rays of the fins moſtly branched; lateral line obſolete. The ſpecies inhabits Amboina.

LANCEOLATUS. Tail very long and acutely pointed. Bloch. *Gobius oceanicus*, Pallas.

Inhabits the brooks and rivers of Martinico, where Plumier ſaw it in great abundance. The body is oblong, and covered with round imbricated ſcales, which are larger on the poſterior part. The head is long and truncated; the eyes vertical with black pupil, and golden iris; jaws equal; tongue looſe and acute; cheeks blueiſh edged with red; lateral line in the middle of the body, and the vent nearer the head; dorſal and anal fins with ſimple, ſoft, diſtant rays, connected by a thin membrane; rays of the firſt dorſal membrane extended far beyond the membrane; between the dorſal fins on each ſide a brown ſpot; pectoral fin yellow edged with blue; tail at the baſe greeniſh yellow, the edge violet. The fleſh excellent.

MINUTUS. Whitiſh, ſpotted with ferruginous: rays of the dorſal and caudal fins obſcurely ſtreaked with the latter. Donov. *Gobius minutus; albicans ferrugineo-maculatus, radiis dorſalibus, et caudalibus ferrugineo obſolete ſtriatis*, Pallas. *Minute or ſpotted goby*, Pennant.

"The minute or ſpotted goby is a pretty, delicate, little creature, whoſe uſual length very rarely exceeds two inches and a half, or at the utmoſt three inches. Pallas, who deſcribes this ſpecies, defines its character with much preciſion; he ſpeaks eſpecially of the obſolete ſtreaks acroſs the rays of the two dorſal fins and tail, which are ſufficiently diſtinct, except when the fins happen to be conſiderably expanded, at which time they indeed appear as ſo many ſeries of unconnected dots. Theſe ſtreaks or dots are uniformly conſtant in all the ſpecimens of the fiſh that have fallen under our obſervation, varying a trifle only in the tint or denſity of colour.

"Bloch does not include this ſpecies in either of his works on fiſhes. Pennant conſiders it as the Gobius aphya of Linnæus, in which particular later writers are miſtaken; it muſt however be confeſſed, that there ſtill remains ſome little doubt as to the preciſe difference between the aphya and minutus; Linnæus tells us the former has the body and fins barred with brown, and this will, in a certain degree, apply to the characters of minutus. That the ſpotted goby is the minutus of Pallas cannot admit of doubt.

"It has been imagined, on the authority of Mr. Pennant, that the ſpotted goby appeared on our coaſts only during the ſummer months, and was beſides extremely local. This idea is certainly unfounded, for we have received them from various parts of the ſea-coaſt in all ſeaſons of the year In the wide ſweep of ſands, called Traeth Levan, which extends along the ſouth-ſide of Beaumaris bay; upon the ſhores of the Severn; and alſo many other of our ſandy coaſts, this diminutive fiſh has attracted our remark ſwimming or lurking among the ſhrimps in the ſhallow pools left by the ſea at ebb-tide. The ſame ſpecies is likewiſe not unfrequently captured with the ſprats, at a ſhort diſtance from the ſhore.

"In the firſt dorſal fin are ſix rays, in the ſecond eleven; the pectoral fin contains twenty rays; the ventral, nineteen; anal, eleven; and tail ſixteen."

We have been the more explicit in detailing the character and hiſtory of the ſpotted goby, in order to enable the reader to comprehend the preciſe difference between this and the following ſpecies.

APHYA. Body and fins barred with brown. Linn. Muſ. Ad. Fr. *Gobius uncialis, pinna dorſi ſecunda oſſiculorum* 17, Art

Deſcribed as a very ſmall ſpecies found in the Nile and ſome parts of the Mediterranean; the length about an inch. The firſt dorſal fin, as in minutus, contains ſix rays, the ſecond ſixteen or ſeventeen; pectoral, according to Linnæus, eighteen, or one leſs, as Artedi mentions. Linnæus ſtates the number of rays in the ventral fin at twelve, Artedi at only ſix, and in deſcribing thoſe of the anal fin they differ again, theſe being, as Artedi informs us, no more than eleven, though Linnæus ſays they amount in number to no leſs than fourteen.

JOZO. Rays of the dorſal fin ſetaceous, and extending above the membrane. Linn. *Jozo*, Salv. *Gobius albus*, Rendel. *Gobius tertius*, Will.

This is an inhabitant of the European and Mediterranean ſeas; its length is from four to ſix inches; the body above brown, beneath whitiſh, and the whole covered with ſcales. The head is compreſſed; pupil of the eye black with the iris white; the back ſlightly arched; jaws of equal length, and armed with numerous ſmall teeth; the lateral line ſtraight, blackiſh, and placed in the middle of the body. The colour of the fins, which is blue, conſtitutes, according to Bloch, the characteriſtic diſtinction of this particular ſpecies. Its haunts are the ſandy ſhores of the ſea, and its food teſtaceous animals, crabs, and other marine creatures. Though highly prolific, it is obſerved not to multiply very faſt, its eggs being eagerly ſought after by the larger kinds of fiſhes. The fleſh is indifferent, being hard and meagre.

Eleotris. Anal fin with nine rays; tail roundiſh. Lagerſtroëm. *Gobius Chinenſis*, Oſbeck.

Whitiſh, covered with large, round, and ſmooth ſcales, and marked on the back near the gill-covers with an ample violet ſpot; both the dorſal fins of equal height, the firſt containing ſix rays, the ſecond eleven; pectoral fin twenty; ventral, ten; anal, nine; and tail ten. The ſpecies inhabits China.

Pectinirostris. Teeth in the lower jaw horizontal. Gmel.—Lagerſtr. *Apocryptes Chinenſis*, Oſbeck.

A fiſh of ſmall ſize found in China: the firſt dorſal fin contains five rays, the ſecond twenty-ſix; pectoral, nineteen; central, twelve; anal, twenty-five; and caudal, fifteen.

Bicolor. Fuſcous; all the fins black. Linn.—Brünn piſc.

Length from three to four, or rarely exceeding ſix inches, and inhabits the Mediterannean ſea. The rays of the fins project very inconſiderably above the connecting membrane.

Cruentatus. Mouth puſtulate with red; rays of the dorſal fins reaching above the membrane. Brünn.

About a ſpan in length, the mouth, gill-covers, chin, and fins puſtulate with ſanguineous red ſpots; beneath the eyes a tranſverſe membranaceous line, and two others placed longitudinally before the dorſal fin; fins generally browniſh, with ſetaceous rays; pectoral rounded; ventral blueiſh, with the rays ſplit at the end; tail pointed and ſlightly banded with black. Gmelin is inclined to think this may be only a variety of the ſpecies Jozo.

Paganellus. Tail and ſecond dorſal fin purpliſh at the baſe; the firſt dorſal fin edged with a yellowiſh line. Linn. *Gobius paganellus*, Haſſelquiſt.

Length three, four, or ſix inches; the body ſlightly compreſſed and whitiſh, with a green tinge, and marked with blackiſh dots or ſmall ſpots. Native of the Mediterranean.

Arabicus. Five poſterior rays of the firſt dorſal fin terminating in a red filament twice the length of the membrane. Forſk.

Native of Djidda in Arabia. The body is about the ſize of the little finger, and of a greeniſh-brown colour, with numerous confluent violet ſpots and ſpecks of blue; ſkin ſoft and covered with minute firm ſcales; fins ſpotted; tail cuneated.

Nebulosus. Second ray of the firſt dorſal fin ending in a black filament twice as long as the body. Forſk.

Inhabits the ſame ſea as the former, and nearly the ſame ſize; body whitiſh, with brown clouded confluent ſpots, beneath white without ſpots; ſcales rhombic and rigid; pectoral fins glaucous, with obſolete brown ſpots at the baſe; ventral browniſh; dorſal fin and tail tranſparent, dotted with brown; anal fin hyaline, with the outer edge black.

Plumieri. Upper jaw prominent. Bloch.

This, according to Plumier, inhabits the rivers of the Antilles in great numbers, and is in much eſteem for the table, its fleſh being of good flavour, and very wholeſome. The body is round, fleſhy, above tawny, yellow on the ſides and white beneath; the whole covered with ſmall ſcales; head large; vent in the middle of the body; lateral line ſtraight; fins yellow; pectoral and caudal yellow at the edge, with branched rays; dorſal and anal with ſimple rays.

Ocellaris. Upper jaw longer; firſt dorſal fin ſix-rayed, with a black ocellated ſpot near the baſe on the poſterior part. Brouſſonet.

Found in the freſh waters of Otaheitee. The head is rather compreſſed, ſub-conic, blackiſh, above ſlightly curved, obtuſely carinated in the middle; teeth unequal, and minute, thoſe of the lower jaw ſmaller; body compreſſed, lanceolate, covered on the poſterior part with imbricated, ciliated ſcales, and obſcurely clouded with olive and black; beneath glaucous.

Niger. Blackiſh varied, ſecond dorſal fin with about fourteen rays. Artedi. *Gobius niger*, Donov. Brit. Fiſhes. *Apocryptes Cantonenſis*, Oſbeck. *Black goby.*

Native of the European and Aſiatic ſeas. Length ſix inches; colour blueiſh black, varied.

Boscii. Body and tail grey, ſpeckled with brown; the former marked with ſeven tranſverſe whitiſh bands. Lacépede.

Deſcribed and figured in the work of Lacépede, on the authority of Boſc, who obſerved it on the coaſts of North America; it grows to the length of four inches; the head is broader than the body; the firſt four rays of the anterior dorſal fin terminate in a filament; and the body, which is ſmooth, is apparently without ſcales. The fleſh is never eaten.

Cæruleus. Body blue; caudal fin red, with black border. Lacépede.

Inhabits the ſeas on the eaſtern coaſts of Africa, where it was obſerved by Commerſon, who deſcribes its appearance in the water, when the ſun ſhines, as ſplendid in the higheſt degree, though its ſize is ſmall, the total length not exceeding three inches. The firſt dorſal is ſomewhat triangular, with the rays terminating in filaments, the ſecond contains fourteen rays, the filamentous appendice of the laſt ray in which is thrice the length of the reſt. The fleſh is not eaten by the natives, but is uſed as bait in fiſhing.

** Section. *Pectoral fins attached or placed on a fleſhy proceſs or elongation.*

Schlosseri. Blackiſh-brown, beneath whitiſh; rays of the firſt dorſal fin ſpinous. Pallas. *Schloſſerian goby.*

This is about a ſpan in length, the body, rather compreſſed, decreaſing in an inconſiderable degree towards the tail, and covered with large round coriaceous ſcales; the head long, much thicker than the body, and ſloping in front; the mouth tranſverſe; lips thick, fleſhy, granulous within, and the upper one folded; teeth large, unequal, diſtant, and irregularly alternate; palate fleſhy; tongue thick, ſoft, and fleſhy; the eyes vertical and placed forward, protuberant, the pupils turned to the ſides with a large lunate cavity beneath each; gill-covers oblong and ſcaly; tail ovate-acute; and the vent in the middle of the body. In the firſt dorſal fin are eight rays, in the ſecond thirteen; pectoral, ſixteen; ventral, twelve; anal, twelve; and tail nineteen. The ſpecies inhabits the freſh waters in the iſland of Amboina, generally reſiding in the ſoft mud at the bottom, and ſubſiſting on worms; the fleſh is excellent. The ſame fiſh occurs alſo in many parts of China. In the Gmelinian Syſt. Nat. the ſpecies is deſcribed under two diſtinct names, ſchloſſeri and barbatus, the latter of which Linnæus defines as having the pectoral fins fan-ſhaped, and the firſt dorſal fin with twelve rays, the ſecond thirteen. Lacépede, Boſc, and other late writers agree in conſidering them the ſame.

Genus *Gobioïdes.*

Ventral fins united; dorſal fin one; head ſmall; gill-covers cloſed nearly throughout their contour.

Melanurus. Dorſal fin ſingle; tail black. Gmel. *Le gobioïde queue noire*, Brouſſ. *Black tailed goby.*

Deſcribed by Gmelin on the authority of Brouſſonet's Ichth. dec. I. ; it is mentioned as a ſmall ſpecies, the habitat of which is unknown. Boſc believes it was brought from the South ſea.

Amguillaris. Dorſal fin ſingle ; tail red. Gmel.

The general figure of this ſpecies is ſomewhat anguilliform, or ſhaped like an eel, and like that fiſh the body is fat and ſlippery ; the teeth are ſmall, and project out of the mouth ; the dorſal and anal fin are large, and extend to the tail, with the fin of which they are united ; the colour of the body is pale brown, of the fins red ; the firſt dorſal fin includes fifty-two rays ; the pectoral, twelve ; ventral, ten ; anal, forty-three ; and tail twelve. The fiſh is a native of the coaſt of China and other parts of India.

Smyrnensis. Edge of the jaws formed of a bony plate, and deſtitute of teeth. Lacépede.

Deſcribed on the authority of the new memoirs of the Tranſactions of the Academy of Peterſburg. It is a native of the Mediterranean ; the ſkin very viſcous, and the dorſal fin furniſhed with forty-three rays.

Broussonetti. Body very long and compreſſed ; tail elongated. Lacépede.

Suppoſed to be a native of the Indian ſeas. The example deſcribed by Lacépede appertained to the ſtadtholder's muſeum. The dorſal fin contains thirty-three rays, and extends nearly to the tail, as does likewiſe the anal fin ; the body nearly tranſparent, and the jaws furniſhed with ſmall teeth.

Genus *Gobiomorus.*

Head ſmall ; eyes approximated ; gill-covers cloſed nearly throughout their contour ; dorſal fins two.

* Section. *Pectoral fins connected cloſe to the body.*

Strigatus. Ventral fin divided ; firſt caudal fin ſix-rayed. Brouſſonet.

Native of the Pacific ocean, near Otaheitee. The head is compreſſed, yellow, ſtreaked and ſpotted, and greeniſh yellow above ; body compreſſed, lanceolate and covered with imbricated, ſubquadrated, and ſlightly crenated ſcales ; colour pale blueiſh-green ; beneath whitiſh, with browniſh ſtreaks behind the pectoral fins ; beneath the lateral, on the hind part, varied with obſolete reddiſh ſpots ; firſt dorſal fin green, with red rays and four fillets of the latter colour ; the ſecond dorſal fin with nine red fillets ; pectoral fin pale greeniſh, the marginal rays ſhorter and ſimple ; ventral whitiſh ; anal long, greeniſh-red ; tail round-oval, yellowiſh-green, the rays red and ſimple, with a broad oblique, ſlightly curved reddiſh fillet each ſide.

Dormitor. Upper jaw longeſt ; tail rounded. Lacépede.

Deſcribed from the drawing of Plumier, who ſaw it in the freſh waters and rivers in the marſhes of South America. The ſecond dorſal fin contains eleven rays, and each of the pectoral fins eight.

Gronovii. Ventral fins divided ; firſt dorſal fin ten-rayed ; tail forked. Gmel. *Ceſtrus argenteus*, &c. Klein. *Mugil Americanus*, Ray. *Harder*, Marcgr.

Inhabits the ſeas of South America. The body is ſilvery above, black, and ſpotted on the ſides with black ; ſcales ſmall and imbricated. The head of this ſpecies is naked ; eyes large and lateral ; mouth narrow ; teeth equal, in the jaws and palate ; tongue rounded, thin, ſmooth ; gill-covers ſmooth and roundiſh ; back a little convex ; lateral line curved and parallel to the back ; vent in the middle of the body.

** Section. *Pectoral fins attached or placed on a fleſh proceſs or elongation.*

Koelreuteri. Ventral fins divided ; firſt dorſal fin with eleven rays. Pallas.

Length about nine inches, the body ſoft, fat, and whitiſh-grey ; head long, thick, and convex in front : eyes on the top of the head ; lips doubled and fleſhy ; teeth unequal, conic, the anterior ones larger, and one larger on each ſide above ; aperture of the gills lunated ; lateral line impreſſed ; vent about the middle of the body with a peduncle behind ; fins ſoft ; the firſt on the back large and brown, with a black terminal band, the rays ſpinous ; the ſecond narrower, yellowiſh, with a longitudinal deep brown band, and branched rays ; pectoral fan-ſhaped or oval, and placed on a broad pedicle ; tail oval and lanceolate, with ramoſe rays.

Genus *Gobiomoroïdes.*

Head ſmall, with the eyes approximated ; gill-covers cloſed nearly throughout their contour ; dorſal fin one.

Pisonis. Ventral fins divided ; lower jaw longer. Gmel. *Amore pixuma*, Piſo.

A ſmall ſpecies found in South America. The head is depreſſed and covered with ſcales in ſize equal to thoſe on the back ; the mouth furniſhed with ſeveral rows of teeth ; and the tail rounded.

Gobius *Aſper*, a name given by Geſner and others to a ſpecies of perch called by many *aſper piſciculus*, a name confounding it with many other different fiſhes, and by Linnæus *perca aſper*. It is diſtinguiſhed among the perch tribe by Artedi under the name of the pearch with eight or nine black lines on each ſide. See Perca.

Gobius *Fluviatlis*, or *Gudgeon*. See Cyprinus *Gobio.*

Gobius *Marinus*, or *Goget*. See Gobius *Niger.*

GOBLET, or Gobelet, a kind of drinking cup, or bowl ; ordinarily of a round figure, and without either foot or handle.

The word is French, *gobelet ;* which Salmaſius, and others, derive from the barbarous Latin *cupa*. Budæus deduces it from the Greek κυπελλον, *a ſort of cup.*

Goblets, made of the wood tamariſk, are ranked among medicinal drugs ; becauſe the liquors infuſed a while therein, are ſuppoſed to acquire a quality which renders them good in diſeaſes of the ſpleen.

GOBONE', or Gobony, in *Heraldry*, the ſame as *componé.*

GOBYGANGE, in *Geography*, a town of Bengal ; eight miles S. E. of Goragot.

GOCEY, a town of Hindooſtan, in Allahabad ; 30 miles N. of Gazypour.

GOCH, a town of France, in the department of the Roer, and chief place of a canton, in the diſtrict of Cleves, ſituated on the Niers, ſurrounded with walls in 1291, and containing three churches ; ſix miles S. of Cleves. The place contains 2412, and the canton 12,728 inhabitants, in 19 communes.

GOCHLENIUS, Rodolphus, in *Biography*, a phyſician, was born at Wittemberg in 1572. His father was profeſſor of logic at Marpurg, where the ſubject of this article ſtudied medicine, and obtained the degree of doctor in May, 1601 ; and was himſelf elected profeſſor of philoſophy in 1608, and alſo profeſſor of mathematics in 1612. He died on the 2d of March 1621, at the age of 49. Although his life was not long, by extreme induſtry he had written a conſiderable number of treatiſes, in which he evinced much of the ſpirit of Paracelſus, of whom he was a zealous follower. It is unneceſſary to enumerate the long liſt of titles to his works, which relate to philoſophy, magnetiſm,

netiſm, aſtrology, chiromancy, &c. as well as to medicine. Eloy.

GOCIANO, in *Geography*, a town of the iſland of Sardinia; 30 miles E. of Algeri.

GOCKEL, or GOKELIUS, CHRISTIAN LOUIS, in *Biography*, of Gotha in Thuringia, was born on the 31ſt of December, 1662. In 1685, he was appointed phyſician to the city of Herſpruck, where he acquired great reputation by his practice, and obtained the confidence of ſeveral German princes, eſpecially of the duke of Wirtemberg. His publications likewiſe contributed to extend his fame, conſiſting of a "Medical Surgery," in German, and of ſome papers in the Memoirs of the German academy. He died in Auguſt 1736, aged 74.

With the preceding phyſician we muſt not confound another, called *Everard Gokelius*, who was born at Ulm, in 1636, and practiſed phyſic at Giengen in Suabia. Beſides ſome eſſays in the German language, he publiſhed, 1. "Enchiridion Medico-practicum de Peſte," 1669.—2. "Conſiliorum et Obſervationum Medicinalium Decades VI." 1682.—3. "Gallicinium Medico-practicum, ſive, Conſiliorum, Obſervationum, et Curationum Medicinalium novarum Centuriæ duæ cum dimidia," Ulmæ 1704. Eloy. Dict. Hiſt.

GOCULGUR, in *Geography*, a town of Hindooſtan, in the ſubah of Agra; 16 miles N. W. of Agra.

GOD, an immaterial, intelligent, and free being; of perfect goodneſs, wiſdom, and power; who made the univerſe, and continues to ſupport it, as well as to govern and direct it by his providence.

The Rabbins and Hebraiſts, particularly St. Jerom, and the interpreters, reckon up ten different names of God in Scripture; which are אל, *El*, אלהים, *Elohim*, אלהי, *Elohi*, or in the ſingular, אלה, *Eloah*, צבאות, *Tſebaoth*, עליון, *Elion*, אהיה, *Ehjeh*, ארוני, *Adonai*, יה, *Jah*, שדי, *Shaddai*, יהוה, *Jehovah*: but it is wrong to divide אלהי, from צבאוה; they ſhould be but one name אלהיצבא ת, *Elohetſebaoth*, *i. e. God of hoſts*. Of theſe names there are three which expreſs the eſſence of God, and are proper names; *viz.* אהוה, *Ehjeh*, יה, *Jah*, and יהוה, *Jehovah*: the others are only names of attributes. St. Jerom gives a particular explanation of theſe ten names, in his epiſtle to Marcella; and Buxtorf the younger has an expreſs diſſertation on the ſame, "Diſſertatio de Nominibus Dei." The Jeſuit Souciet has three ſeveral diſcourſes on the three names, *El*, *Shaddai*, and *Jehovah*, printed at Paris, 1715. The Hebrews call the name of God כןארנע אותיוה, and the Greeks, after this example, Τετραγραμματον; as conſiſting of four letters, which it is obſerved to do in moſt languages: thus, in the Hebrew God is called יהוה, *Jehovah*; in the Greek, Θεος; in Latin, *Deus*; in Spaniſh, *Dios*; in Italian, *Idio*; in French, *Dieu*; in the ancient Gauliſh, *Diex*; in ancient German, *Diet*; in the Sclavonic, *Buch*; in Arabic, *Alla*; in the Poliſh, *Bung*; in the Pannonian, *Iſtu*; in the Egyptian, *Tenu*; in the Perſian, *Sire*; in the language of the Magi, *Orſi*. But a diſtinction ought here to be made between the name God, and the name of God; it being the latter, not the former, that in the Hebrew conſiſts of four letters. The name or word God, in the Hebrew, is אלה, *Eloah*, which conſiſts but of three letters; or in the plural, אלהים, *Elohim*, which conſiſts of five. The name of God is יהוה, *Jehovah*; which is the true τετραγραμματον, or the name of four letters among the Hebrews and Greeks. But it is not this name that anſwers to the Greek Θεος, Latin *Deus*, Engliſh *God*, &c. In reality, none of theſe languages have any proper name of *God*, as יהוה, *Jehovah*, is in the Hebrew.

M. Hallenberg, a Swediſh writer, in a work publiſhed at Stockholm in 1796, and entitled "Diſſertatio hiſtorica et philologica de origine nominis Dei *Gud*," &c. ſuggeſts that the names given by different nations to the deity might denote *unity*; as the word *God* itſelf, by which in all the Teutonic dialects the Supreme Being is denominated.

Philologiſts have hitherto conſidered the word *God* as being of the ſame ſignification with *Good*; and this is not denied by M. Hallenberg. But he thinks, that both words originally denoted *unity*; and that the root is אחד *achad*, *unus*; whence the Syr. *Chad* and *Gada*; the Arab. *Abd* and *Gahd*; the Perſic *choda* and *chuda*; the Greek αγαθος and γαθος; the Teutonic *Gud*; the German *Gott*: and our Saxon *God*. The other names of God, this author thinks, are referable to a ſimilar origin.

By his immateriality, intelligence, and freedom, God is diſtinguiſhed from *fate*, *nature*, *deſtiny*, *neceſſity*, *chance*, *anima mundi*, and from all the other fictitious beings, acknowledged by the Stoics, Pantheiſts, Spinoſiſts, and other ſorts of atheiſts.

The knowledge of God, his nature, attributes, word and works, with the relations between him and his creatures, makes the ſubject of the extenſive ſcience called *theology*. In ſcripture God is defined by, "I am that I am; Alpha and Omega; the Beginning and End of all things."

Among philoſophers, he is defined a being of infinite perfection; or in whom there is no defect of any thing which we conceive may raiſe, improve, or exalt his nature.

Among men, he is chiefly conſidered as the firſt cauſe, the firſt being, who has exiſted from the beginning, has created the world, or who ſubſiſts neceſſarily, or of himſelf.

Sir Iſaac Newton chooſes to conſider and define God, not as is uſually done, from his perfections, his nature, exiſtence, or the like; but from his dominion. "The word God, according to him, is a relative term, and has a regard to ſervants; it is true, it denotes a being eternal, infinite, and abſolutely perfect; but a being however eternal, infinite, and abſolutely perfect, without dominion, would not be God.

"The word God," the ſame author obſerves, "frequently ſignifies *Lord*; but every lord is not God: it is the dominion of a ſpiritual being or lord, that conſtitutes God; true dominion, true God; ſupreme, the ſupreme; feigned, the falſe god.

"From ſuch true dominion it follows, that the true God is living, intelligent, and powerful; and from his other perfections, that he is ſupreme, or ſupremely perfect; he is eternal, and infinite; omnipotent, and omniſcient; that is, he endures from eternity to eternity, and is preſent from infinity to infinity.

"He governs all things that exiſt, and knows all things that are to be known: he is not eternity, or infinity, but eternal and infinite: he is not duration or ſpace, but he endures, and is preſent: he endures always, and is preſent every where; and by exiſting always, and every where, he conſtitutes the very thing, duration and ſpace, eternity and infinity.

"Since every particle of ſpace is always, and every indiviſible moment of duration every where, the Creator and Lord of all things can never be *nunquam*, or *nuſquam*.

"He is omnipreſent, not only virtually, but alſo ſubſtantially: for power without ſubſtance cannot ſubſiſt. All things are contained, and move, in him; but without any mutual paſſion: he ſuffers nothing from the motions of bodies;

dies; nor do they undergo any reſiſtance from his omnipreſence.

"It is confeſſed, that God exiſts neceſſarily; and by the ſame neceſſity he exiſts always, and every where. Hence, alſo, he muſt be perfectly ſimilar; all eye, all ear, all brain, all arm, all the power of perceiving, underſtanding, and acting; but after a manner not at all corporeal, after a manner not like that of men, after a manner wholly to us unknown.

"He is deſtitute of all body, and all bodily ſhape; and therefore cannot be ſeen, heard, or touched; nor ought to be worſhipped under the repreſentation of any thing corporeal.

"We have ideas of the attributes of God, but do not know the ſubſtance even of any thing: we ſee only the figures and colours of bodies, hear only ſounds, touch only the outward ſurfaces, ſmell only odours, and taſte taſtes; and do not, cannot, by any ſenſe, or any reflex act, know their inward ſubſtances; and much leſs can we have any notion of the ſubſtance of God.

"We know him by his properties and attributes; by the moſt wiſe and excellent ſtructure of things, and by final cauſes; but we adore and worſhip him only on account of his dominion: for God, ſetting aſide dominion, providence, and final cauſes, is nothing elſe but fate and nature." Newt. Philoſ. Nat. Princip. Math. in calce.

An ingenious divine has wrought theſe thoughts of that admirable philoſopher into form, and ripened them into a more expreſs ſyſtem, in a diſcourſe on this ſubject. Maxwell's Diſc. concerning God.

We ſhall here ſubjoin a compendious abſtract of the principal arguments that have been alleged in proof of the exiſtence of God. The admirable metaphyſician and divine, Dr. Clarke, has demonſtrated this truth, with that clearneſs and force of reaſoning, for which he is ſo eminently diſtinguiſhed, by a ſeries of propoſitions, mutually connected and dependent, and forming a complete and unanſwerable argument in proof both of the being and attributes of the Deity. 1. Something has exiſted from all eternity; for, ſince ſomething now is, ſomething always was: otherwiſe the things that now are muſt have been produced out of nothing, abſolutely and without cauſe; which is plain contradiction in terms. 2. There has exiſted from eternity ſome one unchangeable and independent being: or elſe, there has been an infinite ſucceſſion of changeable and dependent beings produced one from another in an endleſs progreſſion, without any original cauſe at all. From without, this ſeries of beings can have no cauſe of its exiſtence, becauſe it includes all things that are or ever were in the univerſe: nor is any one being in this infinite ſucceſſion ſelf-exiſtent or neceſſary, and therefore it can have no reaſon of its exiſtence within itſelf; and it was equally poſſible, that from eternity, there ſhould never have exiſted any thing at all, as that a ſucceſſion of ſuch beings ſhould have exiſted from eternity. Conſequently, their exiſtence is determined by nothing; neither by any neceſſity of their own nature, becauſe none of them are ſelf-exiſtent; nor by any other being, becauſe no other is ſuppoſed to exiſt. 3. That unchangeable and independent being, which has exiſted from eternity, without any external cauſe of its exiſtence muſt be ſelf-exiſtent, *i. e.* it muſt exiſt by an abſolute neceſſity originally in the nature of the thing itſelf, and antecedent in the natural order of our ideas to our ſuppoſition of its being. For whatever exiſts muſt either have come into being out of nothing without cauſe; or it muſt have been produced by ſome external cauſe; or it muſt be ſelf-exiſtent: but the two former ſuppoſitions are contrary to the two firſt propoſitions. From this laſt propoſition it follows, that the only true idea of a ſelf-exiſtent, or neceſſarily exiſting being, is the idea of a being, the ſuppoſition of whoſe non-exiſtence is an expreſs contradiction; and this idea is that of a moſt ſimple being, abſolutely eternal and infinite, original and independent. It follows alſo, that nothing is ſo certain as the exiſtence of a ſupreme independent cauſe; and likewiſe that the material world cannot poſſibly be the firſt and original being, uncreated, independent, and of itſelf eternal; becauſe it does not exiſt by an abſolute neceſſity in its own nature, ſo as that it muſt be an expreſs contradiction to ſuppoſe it not to exiſt. With reſpect both to its form and matter, the material world may be conceived not to be, or to be in any reſpect different from what it is, without a contradiction. 4 and 5. The ſubſtance or eſſence of the ſelf-exiſtent being is abſolutely incomprehenſible by us; nevertheleſs, many of the eſſential attributes of his nature are ſtrictly demonſtrable, as well as his exiſtence. The ſelf-exiſtent being, having no cauſe of its exiſtence but the abſolute neceſſity of its own nature, muſt of neceſſity have exiſted from everlaſting, without beginning: and muſt of neceſſity exiſt to everlaſting, without end. 6. The ſelf-exiſtent being muſt of neceſſity be infinite and omnipreſent. Such a being muſt be every where, as well as always, unalterably the ſame. It follows from hence, that the ſelf-exiſtent being muſt be a moſt ſimple, unchangeable, incorruptible being; without parts, figure, motion, diviſibility, and other properties of matter, which are utterly inconſiſtent with complete infinity. 7. The ſelf-exiſtent being, muſt of neceſſity be but one; becauſe in abſolute neceſſity there can be no difference or diverſity of exiſtence; and, therefore, it is abſolutely impoſſible, that there ſhould be two independent ſelf-exiſtent principles, ſuch *e. g.* as God and matter. 8. The ſelf-exiſtent and original cauſe of all things muſt be an intelligent being. This propoſition cannot be demonſtrated ſtrictly and properly *à priori;* but a *poſteriori*, the world affords undeniable arguments to prove that all things are the effects of an intelligent and knowing cauſe. The cauſe muſt be always more excellent than the effect; and, therefore, from the various kinds of powers and degrees of excellence and perfection, which viſible objects poſſeſs; from the intelligence of created beings, which is a real diſtinct quality or perfection, and not a mere effect or compoſition of unintelligent figure and motion; from the variety, order, beauty, wonderful contrivance, and fitneſs of all things to their proper and reſpective ends; and from the original of motion, the ſelf-exiſtent creating being is demonſtrated to be intelligent. 9. The ſelf-exiſtent and original cauſe of all things is not a neceſſary agent, but a being endued with liberty and choice. Liberty is a neceſſary conſequent of intelligence: without liberty, no being can be ſaid to be an agent, or cauſe of any thing; ſince to act neceſſarily is really and properly not to act at all, but to be acted upon. Beſides, if the ſupreme cauſe be not endued with liberty, it will follow, that nothing which is not could poſſibly have been; that nothing which is could poſſibly not have been; and that no mode or circumſtance of the exiſtence of any thing could poſſibly have been in any reſpect otherwiſe than it now actually is. Farther, if there be any final cauſe in the univerſe, the ſupreme cauſe is a free agent; and on the contrary ſuppoſition, it is impoſſible that any effect ſhould be finite: and in every effect, there muſt have been a progreſſion of cauſes *in infinitum,* without any original cauſe at all. 10. The ſelf-exiſtent being, the ſupreme cauſe of all things, muſt of neceſſity have infinite power; ſince all things were made by him, and are entirely dependent upon him; and all the powers of all things are derived from him, and perfectly ſubject

ject to him; nothing can reſiſt the execution of his will. 11. The ſupreme cauſe and author of all things muſt of neceſſity be infinitely wiſe. This follows from the propoſitions already eſtabliſhed; and the proof *a poſteriori*, of the infinite wiſdom of God, from the conſideration of the exquiſite perfection and conſummate excellency of his works, is no leſs ſtrong and undeniable. 12. The ſupreme cauſe and author of all things muſt of neceſſity be a being of infinite goodneſs, juſtice, and truth, and all other moral perfections; ſuch as become the ſupreme governor and judge of the world. The will of a being, infinitely knowing and wiſe, independent and all-powerful, can never be influenced by any wrong affection, and can never be miſled or oppoſed from without; and, therefore, he muſt do always what he knows fitteſt to be done; that is, he muſt act always according to the ſtricteſt rules of infinite goodneſs, juſtice, and truth, and all other moral perfections, and more particularly, being infinitely and neceſſarily happy and all-ſufficient, he muſt be unalterably diſpoſed to do and to communicate good or happineſs. See Clarke's Demonſtration of the Being and Attributes of God, paſſim.

To this more abſtruſe argument *à priori*, for the exiſtence of God, we may add another, more generally obvious, and carrying irreſiſtible conviction, which is deduced from the frame of the univerſe, and from the traces of evident contrivance and fitneſs of things for one another that occur through all the parts of it. Theſe conſpire to prove, that the material world, which in its nature is originated and dependent, could not have been the effect of chance or neceſſity, but of intelligence and deſign. The beautiful, harmonious, and beneficial arrangement of the various bodies that compoſe the material ſyſtem; their mutual dependence and ſubſerviency; the regularity of their motions, and the aptitude of theſe motions for producing the moſt beneficial effects; and many other phenomena reſulting from their relation, magnitude, ſituation, and uſe, afford unqueſtionable evidences of the creating power and wiſe diſpoſal of an intelligent and almighty agent. The power of gravity, by which the celeſtial bodies perſevere in their revolutions, deſerves our particular conſideration. This power penetrates to the centres of the ſun and planets, without any diminution of its virtue, and is extended to immenſe diſtances, regularly decreaſing, and producing the moſt ſenſible and important effects. Its action is proportional to the quantity of ſolid matter in bodies, and not to their ſurfaces, as is uſual in mechanical cauſes; and, therefore, ſeems to ſurpaſs mere mechaniſm. But however various the phenomena that depend on this power, and may be explained by it, no mechanical principles can account for its effects; much leſs could it have produced, at the beginning, the regular ſituation of the orbs, and the preſent diſpoſition of things. Gravity could not have determined the planets to move from weſt to eaſt in orbits nearly circular, almoſt in the ſame plane; nor could this power have projected the comets with all the variety of their directions. If we ſuppoſe the matter of the ſyſtem to be accumulated in the centre by its gravity, no mechanical principles, with the aſſiſtance of this power, could ſeparate the huge and unwieldy maſs into ſuch parts as the ſun and planets; and, after carrying them to their different diſtances, project them in their ſeveral directions, preſerving ſtill the equality of action and re-action, or the ſtate of the centre of gravity of the ſyſtem. Such an exquiſite ſtructure of things could only ariſe from the contrivance and powerful influences of an intelligent, free, and moſt potent agent. The ſame powers, therefore, which at preſent govern the material univerſe and conduct its various motions, are very different from thoſe which were neceſſary to have produced it from nothing, or to have diſpoſed it in the admirable form in which it now proceeds.

But we ſhould far exceed the proper limits of this article, if, confining our obſervation to the earth, our own habitation, we were to enumerate only the principal traces of deſign and wiſdom, as well as goodneſs, which are diſcernible in its figure and conſtituent parts, in its diurnal and annual motion, in the poſition of its axis with regard to its orbit, in the benefit which it derives from the light and heat of the ſun, and the alternate viciſſitude of the ſeaſons; in the atmoſphere which ſurrounds it, and in the different ſpecies and varieties of vegetables and animals with which it is repleniſhed. No one can ſurvey the vegetable productions of the earth, ſo various, beautiful, and uſeful, nor the various gradations of animal life, in ſuch a variety of ſpecies, all preſerved diſtinct, and propagated by a ſettled law, each fitted to its own element, provided with proper food, and with inſtincts and organs ſuited to its rank and ſituation, and eſpecially with the powers of ſenſation and ſelf-motion, and all more immediately or remotely ſubſervient to the government and uſe of man, without admiring the ſkill and deſign of the original Former. But theſe are more ſignally manifeſted in the ſtructure of the human frame, and in the noble powers and capacities of the human mind; more eſpecially in the moral principles and faculties, which are a diſtinguiſhing part of our conſtitution, and lead to the perception and acknowledgment of the exiſtence and government of God. In thoſe inſtances that have now been recited, and a variety of ſimilar inſtances ſuggeſted by them, or naturally occurring to the notice of the curious and reflecting mind, contrivance is manifeſt, and immediately, without any nice or ſubtle reaſonings, ſuggeſts a contriver. It ſtrikes us like a ſenſation; and artful reaſonings againſt it may puzzle us, without ſhaking our belief. No perſon, for example, that knows the principles of optics, and the ſtructure of the eye, can believe that it was formed without ſkill in that ſcience, and therefore, Sturmius held that the examination of the eye was a cure for atheiſm; and another excellent writer, cited below, obſerves, that if there were no example in the world of contrivance, except that of the eye, it would be alone ſufficient to ſupport the concluſion which we draw from it, as to the neceſſity of an intelligent creator: nor can it be ſuppoſed that the ear was formed without the knowledge of ſounds; or that the male and female, created and preſerved in due proportion, were not formed for each other, and for continuing the ſpecies. All our accounts of nature are full of inſtances of this kind. The admirable and beautiful ſtructure of things for final cauſes exalt our idea of the contriver; and the unity of deſign ſhews him to be one. The great motions in the ſyſtem, performed with the ſame facility as the leaſt, ſuggeſt his almighty power, which gave motion to the earth and the celeſtial bodies, with equal eaſe as to the minuteſt particles; the ſubtility of the motions and actions in the internal parts of bodies, ſhews that his influence penetrates the inmoſt receſſes of things, and that he is equally active and preſent every where. The ſimplicity of the laws that prevail in the world, the excellent diſpoſition of things, in order to obtain the beſt ends, and the beauty which adorns the works of nature, far ſuperior to any thing in art, ſuggeſt his conſummate wiſdom. The uſefulneſs of the whole ſcheme, ſo well contrived for the intelligent beings who enjoy it, with the internal diſpoſition and moral ſtructure of thoſe beings, ſhews his unbounded goodneſs. Theſe are arguments which are ſufficiently open to the views and capacities of the unlearned, while at the ſame time they acquire new ſtrength and luſtre from the diſcoveries of the learned. The Deity's acting and interpoſing in the univerſe ſhew that he governs it as well as formed it; and the depth of his counſels, even in conducting the material univerſe, of which a great part ſurpaſſes our knowledge, tends to preſerve an inward veneration and awe of this great being, and diſpoſes us to receive what may be otherwiſe revealed to us concerning him. His eſſence, as well as that of all other ſubſtances, is beyond the reach of all our diſcoveries; but his attributes clearly appear in his admirable works. We know that the higheſt conceptions we are able to form of them are ſtill beneath his real perfections; but his dominion over us, and our duty towards him, are manifeſt. See Maclaurin's Account of Sir I. Newton's Phil. Diſc. book iv. chap. 9.

Thoſe who wiſh to ſee the argument, which has been now ſketched out in ſome of its leading outlines, more fully illuſtrated and urged, may conſult the works of Ray, Nieuwentyt, Baxter in his Matho, Derham, De la Pluche in his Nature diſplayed, &c.; and more eſpecially archdeacon Paley in his "Natural Theology, or Evidences of the Exiſtence and attributes of the Deity, collected from the appearances of Nature." This admirable work, if our limits would allow it, would enable us very much to enrich this article. One atheiſtic way, ſays this much approved and popular writer, of replying to our obſervations upon the works of Nature, and to the proofs of a Deity which we think that we perceive in them, is to tell us, that all which we ſee muſt neceſſarily have had ſome form, and that it might as well be in its preſent form as any. Let us now apply this anſwer to the eye.—"Something or other muſt have occupied that place in the animal's head; muſt have filled up, we will ſay, that ſocket; we will ſay alſo, that it muſt have been of that ſort of ſubſtance, which we call animal ſubſtance, as fleſh, bone, membrane, cartilage, &c.; but that it ſhould have been an eye, knowing as we do what an eye comprehends, *viz.* that it ſhould have conſiſted, firſt, of a ſeries of tranſparent lenſes, (very different, by the bye, even in their ſubſtances from the opaque materials of which the reſt of the body is, in general at leaſt, compoſed; and with which the whole of its ſurface, this ſingle portion of it excepted, is covered): ſecondly, of a black cloth or canvas (the only membrane of the body which is black) ſpread out behind theſe lenſes, ſo as to receive the image formed by pencils of light tranſmitted through them; and placed at the preciſe geometrical diſtance at which, and at which alone, a diſtinct image could be formed, namely, at the concourſe of the refracted rays; thirdly, of a large nerve communicating between this membrane and the brain; without which the action of light upon the membrane, however modified by the organ, would be loſt to the purpoſes of ſenſation. That this fortunate conformation of the parts ſhould have been the lot, not of one individual out of many thouſand individuals, like the great prize in a lottery, or like ſome ſingularity in nature, but the happy chance of a whole ſpecies; nor of one ſpecies out of many thouſand ſpecies, with which we are acquainted; but of by far the greateſt number of all that exiſt, and that under varieties, not caſual or capricious, but bearing marks of being ſuited to their reſpective exigences; that all this ſhould have taken place, merely becauſe ſomething muſt have occupied theſe points in every animal's forehead; or that all this ſhould be thought to be accounted for by the ſhort anſwer, "that whatever was there muſt have had ſome form or other," is too abſurd to be made more ſo by any argumentation."—"Nor does it mend the anſwer to add, with reſpect to the ſingularity of the conformation, that, after the event, it is no longer to be computed what the chances were againſt it This is always to be computed, when the queſtion is, whether an uſeful or imitative conformation be the produce of chance or not. I deſire no greater certainty in reaſoning than that by which chance is excluded from the preſent diſpoſition of the natural world. Univerſal experience is againſt it. What does chance ever do for us? In the human body, for inſtance, chance, *i. e.* the operation of cauſes without deſign, may produce a wen, a wart, a mole, a pimple, but never an eye. Among inanimate ſubſtances, a clod, a pebble, a liquid drop, might be; but never was a watch, a teleſcope, or organized body of any kind, anſwering a valuable purpoſe by a complicated mechaniſm, the effect of chance. In no aſſignable inſtance hath ſuch a thing exiſted, without intention, ſomewhere."[*] Some have ſaid "that the eye, the animal to which it belongs, every other animal, every plant, and every organized body which we ſee, are only ſo many out of the poſſible varieties and combinations of being, which the lapſe of infinite ages has brought into exiſtence; and that the preſent world is the relict of that variety."—But "there is no foundation whatever for this conjecture in any thing which we obſerve in the works of nature: no ſuch experiments are going on at preſent! No ſuch energy operates as that which is here ſuppoſed, and which ſhould be conſtantly puſhing into exiſtence new varieties of beings; nor are there any appearances to ſupport an opinion that every poſſible combination of vegetable or animal ſtructure has formerly been tried." Should it be ſaid that the parts of animal bodies "were not intended for the uſe, but that the uſe aroſe out of the parts; this diſtinction is intelligible."—But "there is little place for it in the works of nature. When roundly and generally affirmed of them, as it has ſometimes been, it amounts to ſuch another ſtretch of aſſertion, as it would be to ſay, that all the implements of the cabinet-maker's workſhop, as well as his fiſh-ſkin, were ſubſtances accidentally configurated, which he had picked up and converted to his uſe; that his adzes, ſaws, planes, and gimlets, were not made, as we ſuppoſe, to hew, cut, ſmooth, ſhape-out, or bore wood with; but, that theſe things being made, no matter with what deſign, or whether with any, the cabinet-maker perceived that they were applicable to his purpoſe, and turned them to account." If this kind of ſolution "be applied to thoſe parts of animals, the action of which does not depend upon the will of the animal, it is fraught with ſtill more evident abſurdity. Is it poſſible to believe that the eye was formed without any regard to viſion, that it was the animal itſelf which found out, that though formed with no ſuch intention, it would ſerve to ſee with; and that the uſe of the eye, as an organ of ſight, reſulted from this diſcovery, and the animal's application of it? The ſame queſtion may be aſked of the ear: the ſame of all the ſenſes," none of which depend upon the election of the animal; nor conſequently upon his ſagacity or experience. "Others have choſen to refer every thing to a *principle of order* in nature. A principle of order is the word; but what is meant by a principle of order, as different from an intelligent creator, has not been explained either by definition or example; and without ſuch explanation, it ſhould ſeem to be a mere ſubſtitution of words for reaſons, names for cauſes."—"Was a watch ever produced by a principle of order; and why might not a watch be ſo produced as well as an eye?"—"The confidence," continues the author now cited, "which we place in our obſervations upon the works of nature, in the marks which we diſcover of contrivance, choice, and deſign, and in our reaſoning upon the proofs afforded us, ought not to be ſhaken, as it is ſometimes attempted to be done, by bringing forward to our view our own ignorance, or rather the general imperfection of our knowledge of nature."—"True fortitude of underſtanding conſiſts in not ſuffering what we know to be diſturbed by what we do not know. If we perceive an uſeful end, and means adapted to that end, we perceive enough for our concluſion. If theſe things be clear, no matter what is obſcure. The argument is finiſhed."—"Our ignorance of many points need not ſuſpend our aſſurance of a few."—"Contrivance," ſays our author, "if eſtabliſhed, appears to me to prove every thing which we wiſh to prove. Amongſt other things, it proves the *perſonality* of the Deity, as diſtinguiſhed from what is ſometimes called nature, ſometimes called a principle: which terms, in the mouths of thoſe who uſe them philoſophically, ſeem to be intended, to admit and expreſs an efficacy, but to exclude and deny a perſonal agent. Now that which can contrive, which can deſign, muſt be a perſon. Theſe capacities conſtitute perſonality, for they imply conſciouſneſs and thought. They require that which can perceive an end or purpoſe; as well as the power of providing means, and of directing them to their end. They require a centre, in which perfections unite, and from which volitions flow; which is mind. The acts of a mind prove the exiſtence of a mind;" and that, whatever it be, in which a mind reſides, is a perſon,—"Whenever we ſee marks of contrivance, we are led for its cauſe to an *intelligent* author. And this tranſition of the underſtanding is founded upon uniform experience."—"There may be many ſecond cauſes, and many cauſes of ſecond cauſes, one behind another, between what we obſerve of nature and the Deity; but there muſt be intelligence ſomewhere; there muſt be more in nature than what we ſee; and amongſt the things unſeen, there muſt be an intelligent deſigning author;"—"after all the ſtruggles of a reluctant philoſophy, the neceſſary reſort is to a deity. The marks of *deſign* are too ſtrong to be got over. Deſign muſt have had a deſigner. The deſigner muſt have been a perſon. That perſon is God." But we muſt content ourſelves with earneſtly recommending the works from which theſe detached extracts are made, to the peruſal of our readers; for we cannot do juſtice to the author's admirable reaſoning.

Another argument to prove the exiſtence of God, as the creator and governor of the univerſe, may be deduced from the univerſal conſent of mankind, and the uniform tradition of this belief through every nation and every age; it is impoſſible to conceive, that a fallacy ſo perpetual and univerſal, ſhould be impoſed on the united reaſon of mankind. No credible and ſatisfactory account can be given of this univerſal conſent, without aſcribing it to the original conſtitution of the human mind, in conſequence of which it cannot fail to diſcern the exiſtence of a deity, and to the undeniable traces of his being, which his works afford. Fear, ſtate-policy, and the prejudices of education, to which the concurrence of mankind in this principle has been ſometimes reſolved, are founded on this univerſal principle, ſuppoſe its being and influence, and are actuated by it. It is much more reaſonable to imagine, that the belief of a God was antecedent to their operation, than that it ſhould have been produced by them; and that it was dictated by reaſon and conſcience, independent of the paſſions and policy of men. The uniform and univerſal tradition of this belief, and of the creation of the world by the divine power, affords concurring evidence both of the principle and of the fact.

The exiſtence of God is alſo farther evinced by thoſe arguments which have been uſually alleged to prove, that the world had a beginning, and, therefore, that it muſt have been created by the energy of divine power. In proof of this, the hiſtory of Moſes, conſidered merely as the moſt ancient hiſtorian, deſerves particular regard. His teſtimony is confirmed by the moſt ancient writers among the heathens, both poets and hiſtorians. It may be alſo fairly alleged, that we have no hiſtory or tradition more ancient than that which agrees with the received opinion of the world's beginning, and of the manner in which it was produced; and that the moſt ancient hiſtories were written long after that time. And this conſideration is urged by Lucretius, the famous Epicurean, as a ſtrong preſumption that the world had a beginning.

> "——— Si nulla fuit genitalis origo
> Terrarum et cœli, ſemperque æterna fuere:
> Cur ſupra bellum Thebanum, et funera Trojæ,
> Non alias alii quoque res cecinere poetæ?"

Beſides, the origin and progreſs of learning, and the moſt uſeful arts, confirm the notion of the world's beginning, and of the common era of its creation; to which alſo may be added, that the world itſelf, being material and corruptible, muſt have had a beginning; and many phenomena occur to the obſervation of the aſtronomer and natural hiſtorian, which furniſh a ſtrong preſumption that it could have had no long duration, and that it gradually tends to diſſolution. From all theſe conſiderations we may infer the exiſtence, attributes, and providence of God. If we admit miracles, as facts authenticated by credible hiſtory, theſe, conſidered as deviations from the eſtabliſhed courſe of nature, afford independent evidence of the being of God. See MIRACLE.

GOD is alſo uſed in ſpeaking of the falſe deities of the heathens, many of which were only creatures to which divine honours and worſhip were ſuperſtitiouſly paid.

The Greeks and Latins, it is obſervable, did not mean, by the name God, an all-perfect being, whereof eternity, infinity, omnipreſence, &c. were eſſential attributes: with them, the word only implied an excellent and ſuperior nature; and, accordingly, they give the appellation gods to all beings of a rank, or claſs, higher and more perfect than that of men; and eſpecially to thoſe who were inferior agents in the divine adminiſtration, all ſubject to the one ſupreme.

Thus men themſelves, according to their ſyſtem, might become gods, after death; inaſmuch as their ſouls might attain to a degree of excellence ſuperior to what they were capable of in life.

The firſt divines, father Boſſu obſerves, were the poets: the two functions, though now ſeparated, were originally combined; or, rather, were one and the ſame thing. Now the great variety of attributes in God, that is, the number of relations, capacities, and circumſtances, wherein they had occaſion to conſider him, put theſe poets, &c. under a neceſſity of making a partition, and of ſeparating the divine attributes into ſeveral perſons: becauſe the weakneſs of the human mind could not conceive ſo much power and action in the ſimplicity of one ſingle divine nature. Thus the omnipotence of God came to be repreſented under the perſon and appellation of Jupiter; the wiſdom of God under that of Minerva; the juſtice of God under that of Juno.

The firſt idols, or falſe gods, that are ſaid to have been adored, were the ſtars, ſun, moon, &c. on account of the light, heat, and other benefits which we derive from them. (See IDOLATRY.) Afterwards the earth came to be deified, for furniſhing fruits neceſſary for the ſubſiſtence of men and animals; then fire and water became objects of divine worſhip, for their uſefulneſs to human life. In proceſs of time, and by degrees, gods became multiplied to infinity; and there was ſcarce any thing but the weakneſs, or caprice of ſome devotee or other, elevated into the rank of deity; things uſeleſs, or even deſtructive not excepted.

The principal of the ancient gods, whom the Romans called *dii majorum gentium*, and which Cicero calls *celeſtial gods*, Varro *ſelect gods*, Ovid *nobiles deos*, others *conſentes deos*, were Jupiter, Juno, Veſta, Minerva, Ceres, Diana, Venus, Mars, Mercury, Neptune, Vulcan, and Apollo. Jupiter is conſidered as the god of heaven; Neptune as god of the ſea; Mars as the god of war; Apollo of eloquence, poetry, and phyſic; Mercury of thieves, Bacchus of wine, Cupid of love, &c.

A ſecond ſort of gods, called *demi-gods*, *ſemi-dii*, *dii minorum gentium*, *indigetes*, or gods adopted, were men canonized and deified. As the greater gods had poſſeſſion of heaven by their own right; theſe ſecondary deities had it by right and donation; being tranſlated into heaven becauſe they had lived as gods upon earth.

The heathen gods may be all reduced to the following claſſes:

1. Created ſpirits, angels, or dæmons: whence good and evil gods; Genii, Lares, Lemures, Typhones, guardian gods, infernal gods, &c.

2. Heavenly bodies; as the ſun, moon, and other planets: alſo the fixed ſtars, conſtellations, &c.

3. Elements; as air, earth, ocean, Ops, Veſta; the rivers, fountains, &c.

4. Meteors. Thus the Perſians adored the wind: thunder and lightning were honoured under the name of Geryon; and ſeveral nations of India and America have made themſelves gods of the ſame. Caſtor, Pollux, Helena, and Iris, have alſo been preferred from meteors to be gods; and the like has been practiſed in regard to comets: witneſs that which appeared at the murder of Cæſar. Socrates deified the clouds, if we may give credit to Ariſtophanes; and the primitive Chriſtians, Tertullian aſſures us, were reproached with the ſame thing.

5. They erected minerals, or foſſils, into deities. Such was the Bætylus; the Finlanders adored ſtones; the Scythians iron; and many nations ſilver and gold.

6. Plants have been made gods. Thus leeks and onions were deities in Egypt; the Sclavi, Lithuanians, Celtæ, Vandals, and Peruvians, adored trees and foreſts; the ancient Gauls, Britons, and Druids, paid a particular devotion to the oak; and it was no other than wheat, corn, ſeed, &c. that the ancients adored under the names of Ceres and Proſerpina.

7. They took themſelves gods from among the waters. The Syrians and Egyptians adored fiſhes; and the Tritons, Nereids, Syrens, &c. what were they but fiſhes? Several nations have adored ſerpents; particularly the Egyptians, Pruſſians, Lithuanians, Samogitians, &c.

8. Inſects, as flies and ants, had their prieſts and votaries: theſe among the Theſſalians, and thoſe in Acarnania, where bullocks were offered to them.

9. Among birds, the ſtork, raven, the ſparhawk, ibis, eagle, griffon, and lapwing, have had divine honours; the laſt in Mexico, the reſt in Egypt, and at Thebes.

10. Four-footed beaſts have had their altars; as the bull, dog, cat, wolf, baboon, lion, and crocodile, in Egypt, and elſewhere; the hog in the iſland of Crete; rats and mice in the Troas, and at Tenedos; weaſels at Thebes, and the porcupine throughout all Zoroaſter's ſchool.

11. Nothing was more common than to place men among the number of deities; and from Belus or Baal, to the Roman emperors before Conſtantine, the inſtances of this kind are innumerable: frequently they did not wait ſo long as their deaths for the apotheoſis. Nebuchadnezzar procured his ſtatue to be worſhipped while living; and Virgil ſhews that Auguſtus had altars and ſacrifices offered to him, Eclog. i. 6, 7 As we learn, from other hands, that he had prieſts called *Auguſtales*; and temples at Lyons, Narbona, and ſeveral other places; and he muſt be allowed the firſt of the Romans, in whoſe behalf idolatry was carried to ſuch a pitch. The Ethiopians deemed all their kings gods: the Velleda of the Germans; the Janus of the Hungarians; and the Thaut, Woden, and Aſſa, of the northern nations, were, indiſputably, men.

12. Not men only, but every thing that relates to man, has alſo been deified: as labour, reſt, ſleep, youth, age, death, virtues, vices, occaſion, time, place, numbers, among the Pythagoreans; the generative power, under the name of Priapus. Infancy, alone, had a cloud of deities; as Vagetanus, Levana, Rumina, Edufa, Potina, Cuba, Cumina, Carna, Oſſilago, Statulinus, Fabulinus, &c.

They alſo adored the gods health, fever, fear, love, pain, indignation, ſhame, impudence, opinion, renown, prudence, ſcience, art, fidelity, felicity, calumny, liberty, money, war, peace, victory, triumph, &c.

Laſtly, nature, the univerſe, or *το παν*, was reputed a great god.

Heſiod has a poem under the title of Θεογονια, *i. e.* the generation of the gods; wherein he explains their genealogy and deſcent; ſets forth who was the firſt, and principal; who next deſcended from him, and what iſſue each had: the whole making a ſort of ſyſtem of heathen theology.

Beſide this popular theology, each philoſopher had his ſyſtem: as may be ſeen from the Timæus of Plato, and Cicero De Natura Deorum.

Juſtin Martyr, Tertullian in his Apologetics, and in his book Contra Gentes; Arnobius, Minutius Felix, Lactantius, Euſebius, Præpar. & Demonſt. Evangel. St. Auguſtine De Civit. Dei, and Theodoret Adverſ. Gentes, ſhew the vanity of the heathen gods.

It is very difficult to diſcover the real ſentiments of the heathens with reſpect to their gods: they are exceedingly intricate and confuſed, and even frequently contradictory. They admitted ſo many ſuperior and inferior gods, who ſhared the empire, that all was full of gods. Varro reckons up no leſs than 30,000 adored within a ſmall extent of ground, and yet their number was every day growing. The way to heaven was ſo eaſy for the great men of thoſe days, that Juvenal brings in Atlas complaining he was ready to ſink under the load of ſuch a number of new gods as were daily placed in the heavens: yet father Mourgues ſeems to have proved that all the philoſophers of antiquity have acknowledged that there was but one God. GODAGARY, in *Geography*, a town of Bengal; 18 miles N. of Moorſhedabad.

GODALMING, a market town and pariſh in the county of Surry, England, contains 474 houſes and 3405 inhabitants. The town is built in a valley, on the banks of the river Wey, which is divided into ſeveral ſmall ſtreams here. The chief of theſe is navigable to Weybridge, where it unites its waters with the Thames. In the vicinity of the town are ſome corn-mills, and paper-mills. Here are ſeveral manufactories for weaving ſtockings, patent fleecy hoſiery, and coarſe woollen cloths; wool-combing and ſpinning of worſted alſo conſtitute part of the trade of the place. The pariſh of Godalming is divided into nine tythings, and the whole is governed by a warden, eight aſſiſtants, and a bailiff. The church is diſtinguiſhed by its handſome ſpire. In the town are a quakers' meeting-houſe, two chapels for diſſenters, a charity ſchool, and in the immediate vicinity is an hoſpital for the accommodation of ten poor men. A ſingular impoſition on public credulity and curioſity was practiſed in this town about the year 1726. A female, named Mary Tofts, circulated a report that ſhe was pregnant with rabbits, and alſo excited a very general belief that ſhe had actually been delivered of ſome of theſe animals. The impoſition, like that of "the Cock-lane ghoſt," was ſupported with ſo much cunning and addreſs, that many perſons, among whom were ſome of the faculty, were deceived, and, for ſome time, credited the tale. Godalming has a weekly market on Saturday, and two annual fairs. Manning's Hiſtory and Antiquities of Surrey, folio.

GODAMA, GODEMA, *Gaudma*, *Gotma*, or *Goutam*, in *Indian Mythology*, different names applied in various parts of India, and particularly in the Birman empire, to their deity Budha, or Boodh. (See BOODH.) Godama or Kodama is the moſt common appellation among his worſhippers in India beyond the Ganges; it ſeems alſo to be common among the Hindoos, who, according to the idiom of the Sanſcrit, write it Gotamas. This name, as ſome ſay, literally ſignifies cow-herd, but metaphorically king; and, according to others, the meaning of Godama is eminently wiſe, or a ſage. Many other appellations are given to this deity derived from the poſtures in which his various images repreſent him. Godama was probably an Indian prince, deified by ſuperſtition; and in an ancient treatiſe, giving an account of the religion of Godama, entitled "Zarado," Godama is ſaid to have attained divinity at the age of 35 years, to have preached his law for 45 years, and to have brought ſalvation to all living beings. Dr. Buchanan, who cites this treatiſe (Aſ. Reſ. vol. vi.) places the death of Godama 546 years B. C. The doctrine and laws, ſaid in this treatiſe to be delivered by Godama, conſiſt chiefly in obſerving the five commandments, and in abſtaining from the ten ſins. The five commandments are as follow: 1. From the meaneſt inſect up to man, thou ſhalt kill no animal whatever. 2. Thou ſhalt not ſteal. 3. Thou ſhalt not violate the wife or concubine of another. 4. Thou ſhalt tell nothing falſe. 5. Thou ſhalt drink neither wine, nor any thing that will intoxicate; thou ſhalt not eat opium, or any other inebriating drug. The perſon who keeps theſe five commandments ſhall attain high rank, and ſhall not be liable to poverty, nor to other misfortunes and calamities. The ten ſins are the killing of animals—theft—adultery—falſhood—diſcord—harſh and indignant language—idle and ſuperfluous talk—the coveting of your neighbour's goods—envy, and the deſire of your neighbour's death, or misfortune—and the following of the doctrine of falſe gods. Every one who abſtains from theſe ſins, will ſucceſſively increaſe in virtue through all his ſucceſſive tranſmigrations, till at length he will become worthy of beholding a God, and of hearing his great voice; and he will be exempted from the four human miſeries, *viz.* weight, old age, diſeaſe, and death. The good works required are giving alms, and thoughtfully pronouncing three words. Whoever dies without the abſtinence and good works here preſcribed, will certainly paſs into one of the infernal ſtates, and be doomed to certain tranſmigrations. The prieſts of Godama are called Rahans in the Burma language, and they have alſo beſtowed upon them the title of Somona or Samana, which is likewiſe applied to the images of the divinity when he is repreſented, as he commonly is, in the prieſtly habit. (See RAHANS.) Godama commanded his images and relics to be worſhipped. The largeſt and moſt celebrated temples are generally in the form of a pyramid; and contain ſome of theſe relics, ſuch as a tooth, a bone, a hair, or a garment. To theſe temples the prayers of the devout are addreſſed, and their offerings preſented. The images of the god are of very various materials; clay, copper, ſilver, and alabaſter. Many of them are richly gilt, and adorned with paintings of flowers; they are of different ſizes, ſome being not above ſix inches high, and others of a coloſſal ſtature. Other objects of great veneration among the worſhippers of Godama are ſtones of large dimenſions, carved with various hieroglyphics, and ſaid to repreſent, or to be the impreſſions of his feet. The principal diſciples of Godama are by his followers conſidered as ſaints; and many images of theſe, in a prieſtly habit, accompany that of their maſter. Every true worſhipper of Godama prays before he goes to ſleep, and before he riſes in the morning, which is generally at the dawn of day.

Beſides their private devotions, which are numerous and regularly performed, it is cuſtomary to make offerings at the temple; the ſeaſons for which are thoſe of the four phaſes of the moon, eſpecially the full and change, which may be conſidered as the Burma ſabbaths. Friday is with them reckoned an unfortunate day, and therefore on this day they undertake no buſineſs; but they keep holy no particular day of the week. The ſect of Godama eſteem the opinion of a divine being, who created the univerſe, to be highly impious; and accordingly the followers of Godama are, ſtrictly ſpeaking, atheiſts, as they ſuppoſe every thing to ariſe from fate; and their gods are merely men, who by their virtue acquire ſupreme happineſs, and by their wiſdom become entitled to impoſe a law on all living beings. See BIRMAN *Empire*, and BOODH.

GODANA, in *Geography*, a town of Perſia, in the province of Irak; 105 miles E. of Iſpahan.

GODAVERY, or GONGA GODOWRY, a river of Hindooſtan, ſometimes called the *Gang* in Feriſhta's Hiſtory, was, till very lately, conſidered as the ſame with the Cattack river, or Mahanuddy; but it is now aſcertained to be a different river, which has its ſource about 70 miles N.E. of Bombay; on the weſtern Gauts, more properly called the Sukhien mountains; and, in the upper part of its courſe, at leaſt, is eſteemed a ſacred river by the Hindoos; that is, ablutions performed in its ſtream have a religious efficacy ſuperior to thoſe performed in ordinary ſtreams. The Godavery, after traverſing the Dowlatabad ſoubah, and the country of Tellingana, from weſt to eaſt, turns to the ſouth-eaſt; and receiving the Bain Gonga, about 90 miles above the ſea, beſides many ſmaller rivers, ſeparates into two principal channels at Rajamundry; and thence ſubdividing again, they form altogether ſeveral tide harbours, for veſſels of moderate burden. Ingeram, Coringa, Yanam, Bandarmalanka, and Narſapour, are among the places ſituated at the mouth of this river; which appears to be the moſt conſiderable one between the Ganges and cape Comorin. Extenſive foreſts of teak-trees border on its banks, within the mountains, and ſupply ſhip-timber for the uſe of the ports abovementioned. The Kiſtnah and Godavery rivers, however remote at their fountains, approach within 80 miles of each other in the lower parts of their courſe; and form an extenſive tract of country, compoſed of rich vegetable mould, ſuch as is uſually found at the mouths of large rivers. Rennell. See DELTA.

GOD-BOTE, in our *Ancient Saxon Cuſtoms*, an eccleſiaſtical or church fine, for crimes and offences committed againſt God. Theſe, according to Blackſtone, are *apoſtacy* and *hereſy;* which ſee.

GODDARD, Jonathan, in *Biography*, an eminent phyſician and chemiſt, was born at Greenwich in the year 1617. After ſtudying for four years at Oxford, he ſet out on his travels, and on his return he ſettled in practice in London, having taken his degree at Cambridge. He was elected a fellow of the College of Phyſicians in 1646, and in 1647 was appointed lecturer on anatomy. In conjunction with ſome friends, he formed a ſociety for experimental inquiry, which met at his lodgings in Wood-ſtreet, and in promoting the objects of which he was extremely aſſiduous. Having gained conſiderable reputation, and having, with the reſt of his party, ſided with parliament, he was appointed by Cromwell chief phyſician to the army, and in this capacity accompanied the uſurper to Ireland in 1649, to Scotland in the following year, and thence returned with his maſter, who, after the battle of Worceſter, rode into London in triumph, September 12th, 1651. He obtained many favours from Cromwell, who firſt made him warden of Merton college, Oxford, afterwards ſole repreſentative of that univerſity in the Short Parliament in 1653; and in the ſame year one of the council of ſtate. Theſe favours were ſufficient to procure for him the diſpleaſure of Charles II.; and, being driven from Oxford, he removed to Greſham college, where he had been choſen profeſſor of phyſic in November 1655. Here he continued to frequent thoſe meetings, which gave birth to the Royal Society, and was nominated one of the firſt council of that inſtitution in the charter. Dr. Goddard was a conſcientious and able practitioner. Partly from the love of experimental chemiſtry, principally from a diſtruſt in the knowledge of apothecaries, he prepared his own medicines, and recommended the practice to be adopted by phyſicians in general. Finding numerous obſtacles, however, in his way, he publiſhed "A Diſcourſe, ſetting forth the unhappy condition of the practice of phyſic in London," 1669. But this was of no avail. He died on the 24th of March, 1674, being ſeized with an apoplectic fit in Cheapſide, when returning from one of the philoſophic meetings. Two papers of his were publiſhed in the Philoſophical Tranſactions, N° 137, 138; and many others in Birch's Hiſtory of the Royal Society.

GODDESS, Dea, *Diva*, a heathen deity, to whom they attributed the female ſex.

The ancients had almoſt as many goddeſſes as gods. Such were Juno, the goddeſs of air; Diana, the goddeſs of woods and chaſtity; Proſerpina, the goddeſs of hell; Venus, of beauty; Thetis, of the ſea: ſuch alſo were Victory, Fortune, &c.

Nay they were not contented to make women gods, and admit both ſexes into the roll; but they had alſo hermaphrodite gods. Thus Minerva, according to ſeveral of the learned, was both man and woman, and worſhipped both under the appellation of Lunus and Luna. Mithras, the Perſian deity, was both god and goddeſs, and the ſexes of Venus and Vulcan are very dubious: whence, in the invocations of thoſe deities, they uſed this formula; "Be thou god or goddeſs;" as we learn from A. Gellius. It was a privilege peculiar to goddeſſes, that they might be repreſented, on medals, naked. The imagination, it was ſuppoſed, muſt be awed, and kept from taking liberties, by the conſideration of the divine character.

GODEAU, Anthony, in *Biography*, was born at the city of Dreux in the year 1605. He was educated for civil and active life, but having met with a diſappointment in the object of his affections, he repaired to Paris, where he cultivated the ſociety of men of letters, and was one of the firſt of thoſe who eſtabliſhed the French academy of belles lettres. This ſociety ſuggeſted to the cardinal Richlieu the foundation of the French academy, of which M. Godeau was an original member. He took orders in the year 1735, and having enriched his own mind with the moſt pure maxims of Chriſtian morality, he taught them from the pulpit with much eloquence, and he is ſaid to have practiſed them in all his actions. In the year 1636 he was, by the influence of cardinal Richlieu, nominated to the biſhopric of Graſſe, and from this time he divided his time between his ſtudies, and the diligent diſcharge of his epiſcopal functions. He found the ſtate of eccleſiaſtical diſcipline exceedingly relaxed, and ſet about its reformation; he perſonally examined the qualifications of the clergy, and enquired in what manner they diſcharged the important duties of their office; he frequently preached in different parts of his dioceſe, and exhibited in his own life an admirable model of thoſe virtues which he was anxious to recommend to the attention of his flock. He was in high favour with pope Innocent X. who granted him bulls of union of the biſhopric of Venice with that of Graſſe, but when he found that the people and clergy oppoſed the meaſure, he choſe rather to give up his pretenſions, than break in upon the peace of the church. He died in 1672, at the age of ſixty-ſeven years. He was a conſiderable writer, chiefly on ſubjects connected with his profeſſion, but his moſt important work was "The Hiſtory of the Church from the commencement of the World to the end of the Ninth Century," in three volumes, folio. This is the firſt eccleſiaſtical hiſtory written in the French language; and though compoſed with leſs preciſion than that of the abbé Fleury, it poſſeſſes conſiderable merit. It is characterized by Dupin as "exact, faithful and agreeable:" he farther adds, that it always will have a merit, which neither time, nor any other hiſtory will be able to efface. Beſides the hiſtory, we may notice M. Godeau's "Paraphraſes on the Epiſtles of St. Paul:" "The New Teſtament tranſlated and explained:" "The lives of St. Paul, St. Auguſtine, and St. Charles Borromeo, &c." Moreri.

GODEFROI, Denys, a very learned juriſt, was born at Paris in 1549. He ſtudied at Louvain, Cologne, and Heidelberg, and upon his return to France acquired a high reputation in the parliament, in which he was nominated to a counſellor's place. In 1580 his religious principles obliged him to ſeek a refuge at Geneva, where he was admitted a burgher, and a profeſſor of the law. In 1589 Henry IV. created him bailiff of ſome villages at the foot of mount Jura, and a ſupernumerary counſellor in the parliament of Paris. After this he was deprived of his employment and his valuable library by the invaſion of the duke of Savoy, and in 1594 he accepted the profeſſorſhip of the law in the univerſity of Straſburg. In 1604, at the invitation of Frederick, elector-palatine, he went to ſettle at Heidelberg, and in 1618 that prince ſent him on an embaſſy to Lewis XIII., who received him with marks of high eſteem. He died at Straſburg in 1622, leaving behind him many works that teſtify to his great learning. The titles of theſe are enumerated by Moreri and others, and a few of the principal may be mentioned here: "Corpus Juris civilis cum notis;" this treatiſe has been frequently reprinted: the beſt edition is ſaid to be that from the Elzevir preſs in two volumes folio. "Notæ in IV. Libros Inſtitutionum:" "Praxis Civilis ex antiquis et recentioribus Scriptoribus."

Godefroi, Theodore, the eldeſt ſon of the preceding, was born at Geneva in 1580. He purſued his ſtudies firſt in that city, then at Straſburg, and afterwards at Paris, where he embraced the Catholic religion. In 1643 he obtained the office of counſellor of ſtate, and acted during the ſix laſt years of his life as counſellor and ſecretary to the French embaſſy for the general peace at Munſter. Here he died in 1649. He was particularly verſed in the genealogical and ceremonial hiſtory of France, and publiſhed ſeveral learned works for its illuſtration; ſuch are "Le Ceremonial de France," 4to. "Mem. concernant la Preſſeance des Rois de France ſur les Rois d'Eſpagne:" "De la veritable Origine de la Maiſon d'Auſtriche:" "Traité touchant les Droits du Roi Tres-chretien ſur pluſieurs Etats voiſines," &c. Moreri.

Godefroi, James, brother to Theodore, was born at Geneva in 1587. He followed the ſteps of his father by a ſtrict adherence to the reformed religion, and by purſuing the ſtudies of law, hiſtory, and philoſophy. In 1619 he was created profeſſor of the law at Geneva, and was called to a ſeat in the council in 1629. He filled with the greateſt zeal and ability every public office with which he was entruſted. He was five times elected ſyndic of the republic, and was made ſecretary of ſtate. He was choſen as a fit perſon to conduct various negociations in France, Piedmont, Switzerland, and Germany; and, at the ſame period, he devoted all his leiſure to public lectures in juriſprudence, and compoſed a variety of learned works. He maintained a correſpondence with the moſt learned men of the age, by whom he was greatly reſpected. He died in 1652, and his works bear teſtimony to his profound erudition, and to his great and unwearied induſtry; among them may be mentioned "Fragmenta Duodecim Tabularum;" "Animadverſiones Juris Civilis;" "De Jure Præcedentiæ;" "Codex Theodoſianus," a poſthumous work, regarded as a moſt valuable monument of ancient juriſprudence. He edited the works of Cicero, "cum notis Lambini et Gothofredi." He had likewiſe made large collections for the hiſtory of Geneva, which were afterwards uſed by Spon. Moreri.

Godefroi, Denys, ſon of Theodore, born at Paris in 1615, was an able French hiſtorian. He was author of "Memoires et Inſtructions pour ſervir dans les Negociations et les Affaires concernant les Droits du Roi," a work, which has ſometimes been attributed to the chancellor Seguier, by whoſe order it was compiled. He re-edited many of his father's works, adding to them new illuſtrations with learned notes. He continued to his own time Feron's "Hiſt. des Officiers de la Couronne." As a public man he was appointed in 1668 the director and keeper of the chamber of accounts at Lille in Flanders, where he died in 1681. Moreri.

Godefroi, John, ſon of the preceding, ſucceeded his father in the direction of the chamber of accounts at Lille, where he died, much advanced in years, in 1732. He publiſhed an edition of the "Memoirs of Philip de Comines," in five volumes 8vo. "The Journal of Henry III." "The Memoirs of Queen Margaret." He is ſaid to have contributed more than any other writer to the elucidation of the affairs of the League. Moreri.

GODERVILLE, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the diſtrict of La Havre; 9 miles N.E. of Montvilliers. The place contains 650, and the canton 12,539 inhabitants, on a territory of 150 kiliometres, in 31 communes.

GODESCHALC, in *Biography*, a Benedictine monk, who flouriſhed in the ninth century, was born in Saxony, and was brought up, contrary to his own inclination, to the profeſſion, in the convent of Fulda. He was ordained prieſt when he was about forty years of age, and in 846 we find him at Rome viſiting the holy places there; thence he proceeded to Pannonia and Dalmatia, where he commenced preaching the doctrine of predeſtination with much fervour, which it is ſuppoſed he imbibed from the works of St. Auguſtine. Upon his return to his own country he had a conference with Nothingus, biſhop of Verona, before whom he maintained that God, from all eternity, had pre-ordained ſome to everlaſting life, and others to everlaſting puniſhment and miſery. Nothingus, aſtoniſhed and terrified at ſo daring, and, as he thought, impious a poſition, complained of it to Rabanus, archbiſhop of Mentz, who undertook to confute his error, in writing. Diſſatisfied, perhaps, with his own arguments, Rabanus ſummoned a council to meet at Mentz, in the year 848, to which, however, Godeſchalc preſented a juſtification of his opinions, and reſolutely perſiſted in maintaining them to be conſiſtent with the ſcriptures and the ſenſe of the orthodox fathers. The council paſſed ſentence of condemnation upon him, and ſent him priſoner to Hincmar, archbiſhop of Rheims, within whoſe juriſdiction he had received the prieſthood. Hincmar, who was devoted to the intereſt of Rabanus, aſſembled a council in 849, in which the monk was a ſecond time condemned, and rendered liable to a puniſhment repugnant to all the principles of religion and humanity. Godeſchalc, however erroneous his ſentiments might be, was not to be intimidated; he believed what he aſſerted, and he firmly adhered to the doctrine in ſpite of the higher powers. Hincmar accordingly proceeded to put the ſentence into execution, degraded the monk from the prieſthood, and ordered him to be ſcourged with the utmoſt ſeverity. It appears that he was not prepared for ſo grievous a trial of his fortitude; the force of the pains inflicted on him obliged him, in compliance with the dictates of his proſecutors, to throw into the fire the juſtification of his opinions which he had delivered into the council. The infamous perſecutors were not contented with this triumph; they committed him cloſe priſoner to the monaſtery of Hautvilliers, in the dioceſe of Rheims. In this, as in every other caſe of a ſimilar kind, the ſufferings of Godeſchalc gained him followers and adherents, and many became advocates for his cauſe. A conſiderable ſchiſm was produced in the Latin church. Some confined themſelves to the defence of his perſon and conduct, while others employed all their zeal and talents in the vindication of his doctrine. The ſpirit of the controverſy ran ſo high between the contending parties, that Charles the Bald, in 853, ſummoned the council to meet at Quiercy. Here the ſuffering monk was again condemned, but the decrees of this council were declared null and void, and Godeſchalc and his doctrine vindicated and defended, in a council at Valence, in Dauphiny, in 855, the decrees of which were confirmed in the council of Langres, and in that of Touſi. Such was the origin of the diſputes concerning the doctrines of predeſtination and grace, which, from time to time, have divided the Catholic world into two parties, and which have ſubſiſted in full force among the Proteſtants. The unfortunate Godeſchalc died in priſon about the year 869, maintaining with his laſt breath the doctrine for which he had ſuffered. The only writings of this monk that have come down to the preſent times are, two "Confeſſions of Faith," inſerted in archbiſhop Uſher's "Hiſtoria Godeſchalci," printed at Dublin in 1641; an epiſtle to Ratramnus, publiſhed in Cellot's "Hiſtoria Godeſchalci," at Paris, in 1655, and ſome fragments of other pieces, noticed by Cave. Godeſchalc has immortalized his name by ſetting on foot the controverſy to which we have referred, and by his ſufferings in vindication of his favourite doctrine. In the year 1650, the celebrated Maguin publiſhed at Paris, in two volumes 4to. a collection of the early treatiſes produced on both ſides of this controverſy, entitled "Veterum Auctorum qui nono ſeculo de Prædeſtinatione et Gratia ſcripſerunt, &c."

GOD-FATHERS, and God-Mothers, perſons who direct and attend at the baptiſm of infants, or other perſons; who give the name, and who become ſureties for the faith and good conduct of the infant baptized. Hence they are called *ſuſceptors*, or more commonly *ſponſors*. To this purpoſe Dr. Nichols, (Def. part ii. p. 273.) ſays, that "the ſureties in baptiſm religiouſly engage for the faith of the baptized; that they ſhall ſincerely believe all that is revealed in the goſpel, and ſhall direct the ſubſequent actions of their lives by the laws of Chriſt." Againſt this practice Proteſtant diſſenters have alleged, that the parents, to whom both God and nature have committed the education of their child, are the proper perſons to ſtand forth at its baptiſm, and take upon them this great and important truſt; and to bind themſelves by a ſolemn vow faithfully to diſcharge it. They object to the order and practice of the eſtabliſhed church, that without ſufficient authority from reaſon, or ſcripture, or the ancient practice of the Chriſtian church, parents are ſet aſide in this ſolemnity, and forbidden to ſtand forth, and take upon them this great charge to which God hath called them. For the 29th canon expreſsly commands, "that no parent ſhall be urged to be preſent at his child's baptiſm, nor *be admitted* to anſwer as god-father for *his own* child." They alſo object, that the forms of the church ſhould require other perſons to appear inſtead of the parents, and to take upon them this important truſt, and moſt ſolemnly to promiſe before God and the church the performance of that, which few of them ever do, or perhaps ever intended to perform, or are capable of performing. It has been pleaded, and even generally allowed, that ſponſors in baptiſm were not known or thought of in the primitive apoſtolic church. Tertullian, who lived about A.D. 200, ſeems to have been the firſt of all Chriſtian writers who mentions perſons of this deſcription: "What neceſſity is there," ſays he, (De Baptiſm.) "that ſponſors ſhould expoſe themſelves to danger, who, through death, may fail of the performance of their promiſes, or may be deceived by the wicked diſpoſition of thoſe for whom they promiſe." "Whether the uſe of ſponſors was from the apoſtles' days," (ſays lord King, in his Enquiry into the Conſtitution, &c. of the Primitive Church,) "I cannot determine, unleſs the negative may be conjectured from Juſtin Martyr, Tertullian's ſenior by 50 years, who, when he enumerates the method and form of baptiſm, ſays not one word of ſponſors or god-fathers, as may be ſeen in his ſecond apology, p. 93, 94." St. Auſtin, one of the earlieſt of Chriſtian writers who mention ſponſors, who lived about A.D. 390, informs us when, and upon what occaſion, theſe ſponſors were admitted: "A great many," ſays he, "are offered to baptiſm, not by their parents, but by others, as infant-ſlaves are ſometimes offered by their maſters; and ſometimes when the parents are dead, the infants are baptized, being offered by any who can afford to ſhew this compaſſion to them. And ſometimes infants, whom their parents have cruelly expoſed, to be brought up by thoſe who light on them, are now and then taken up by the holy virgins, and offered to baptiſm by them who have no children of their own, nor deſign to have any." Upon theſe words of Auſtin, Dr. Wall ingenuouſly confeſſes, (Hiſt. Inf. Bapt. vol. i.) "Here we ſee the *ordinary* uſe there was for *parents* to anſwer for the children; but yet that this was not counted ſo *neceſſary*, as that a child could not be baptized without it." Hence it has been inferred, that parents were never ſet aſide, when they were capable and willing to offer their children; and that only in caſes of the incapacity of parents, were ſponſors admitted; and in all ſuch caſes, provided that the practice be not enforced as a Chriſtian inſtitution, and as abſolutely indiſpenſable, the diſſenters, we conceive, could not reaſonably object to it. Mr. Wheatly, a well-known writer on the Common Prayer, obſerves, that the god-fathers and god-mothers of perſons baptized at riper years "are only appointed as *witneſſes* of the engagement, and undertake no more than to remind them hereafter of the vow and profeſſion, which they made in their preſence." And yet our church catechiſm expreſsly aſſerts, and repeats the aſſertion, that the ſponſors, engaging for *infants*, engage that they ſhall believe and repent; for the infants are ſaid to promiſe both theſe things by their ſureties. Free and Candid Diſquiſitions, p. 131.

The number of god-fathers and god-mothers is now reduced to three in the church of England, and two in that of Rome: anciently, they had as many as they pleaſed.

The Romaniſts have alſo god-fathers and god-mothers at their confirmation. They even give god-fathers, &c. to bells, at their baptiſm.

Among the ancients it was the cuſtom for perſons of quality to have others of like quality cut their children's hair the firſt time; by which they became reputed a ſort of god-fathers: and the like was practiſed with regard to the hair of the beard.

God-Father was alſo a name anciently given to a kind of ſeconds, who attended and aſſiſted the knights in tournaments, or ſingle combats.

The god-fathers of duels were a kind of advocates, who were choſen by the two parties, to repreſent the reaſons of their combat to the judges.

Something of this kind was long retained at ſolemn carouſals. There were two or more in each quadrill. See Quadrill.

The inſtitution of god-fathers and god-mothers, *patrimi* and *matrimi*, is originally Roman. They are ſaid to have been people who, in the games of the Circus, attended the chariots, ſhows, and images, of the gods. Cicero makes mention of them, in his oration De Haruſpicum Reſponſis. Their office was much like that of the children in ſome Romiſh ceremonies, who are dreſſed in the habit of angels, to ſtrew flowers, bear incenſe-pots, lights, &c. and accompany the relics and images of ſaints.

GODFREY of Bouillon, in *Biography*, celebrated for the part which he took in the firſt cruſade, and king of Jeruſalem, was the ſon of Euſtace II., count of Boulogne. The appellation of Bouillon was derived from his lordſhip of that name in the Ardennes. In his youth he ſerved in the armies of Henry IV., who, as a reward of his valour and fidelity, conferred upon him the title of duke of Lorrain. When the religious enthuſiaſm of the times ſet on foot an expedition for the recovery of the Holy Land from the poſſeſſion of the Saracens, Godfrey was one of the earlieſt and moſt illuſtrious of the princes who took the croſs. The command of the principal army was entruſted to his care, and it is agreed that none among the leaders were actuated by purer motives than Godfrey. He gave a diſtinguiſhing proof of the diſintereſtedneſs of his conduct, by ſacrificing almoſt all his property to defray the neceſſary expences of the expedition. Godfrey ſet out in the autumn of 1096, and proceeded with his hoſt through Germany and Bulgaria, taking care to abſtain from thoſe acts of hoſtility and rapine which characterized, and had cauſed the deſtruction of the fanatics of Peter the Hermit. It was not till June 1099, that Godfrey was able to lay ſiege to the renowned city, and though his army was greatly diminiſhed in point of numbers, he was able to ſucceed, and on July 15th Jeruſalem was taken by ſtorm. The fanaticiſm and madneſs of the victors indulged themſelves in a horrible maſſacre of the vanquiſhed, which, it is believed, their general and leader was unable to prevent. Godfrey was almoſt immediately proclaimed ſovereign of the new acquiſition, but he refuſed to aſſume the title and enſigns of royalty in the place where Chriſt, in whoſe cauſe he was acting, had been crowned with thorns, and he governed under the modeſt appellation of “Defender and Baron of the Holy Sepulchre.” He was ſoon after attacked by the ſultan of Egypt, but the Chriſtians ſoon put him and his numerous forces to flight, and the whole of Paleſtine was reduced under the power of Godfrey. He eſtabliſhed the feudal inſtitution in his kingdom; and a code of juriſprudence, under the title of “The Aſſize of Jeruſalem,” gave a model of the pureſt form of European liberty in the midſt of Aſiatic deſpotiſm. He died, after he had ſat on the throne about a year, and was ſucceeded by his brother Baldwin. The celebrity of Godfrey is immortalized as the hero of Taſſo's “Jeruſalem Delivered,” one of the nobleſt of epic poems; nor has the bard found it neceſſary to borrow the colours of fiction, in order to throw ſplendour round a character ſo truly eſtimable: “Godfrey,” ſays the hiſtorian in deſcribing his character,” was the firſt who aſcended the walls of Rome, and his ſickneſs, his vow, perhaps his remorſe for bearing arms againſt the pope, confirmed an early reſolution of viſiting the holy ſepulchre, not as a pilgrim, but a deliverer. His valour was matured by prudence and moderation; his piety, though blind, was ſincere, and in the tumult of a camp he practiſed the real and fictitious virtues of a convent. Superior to the private factions of the chiefs, he reſerved his enmity for the enemies of Chriſt; and though he gained a kingdom by the attempt, his pure and diſintereſted zeal was acknowledged by his rivals.” Gibbon Univer. Hiſt. See alſo the article CROISADE.

GODFREY of Viterbo, an Italian hiſtorian of the 12th century, was chaplain and ſecretary to the emperors Conrad III., Frederick I., and Henry IV. According to his own account he was a great traveller for knowledge; and was converſant in ſeveral languages. His principal work was a “Chronicle,” entitled the “Pantheon,” as treating on the “Gods of Earth,” is dedicated to pope Urban III., and is a general hiſtorical record from the creation of the world to the year 1186. It is written in the Latin language, and is deemed very worthy of credit for the events of his own time. It was firſt printed at Baſil in 1559; then at Frankfort in 1584, and afterwards at Hanover in 1613, in the collection of German hiſtorians, edited by Piſtorius. Godfrey was author of a work intitled “Speculum Regum, ſive de Genealogia omnium Regum:” the MS. is preſerved in the Imperial library of Vienna.

GOD-GILD, in our *Ancient Cuſtoms,* that which is offered to God, or for his ſervice.

GODHEAH, or GOOD HOPE, in *Geography*, a ſettlement in Weſt Greenland. N. lat. 64° 25'. W. long. 50° 10'.

GODIN, LOUIS, in *Biography*, was born at Paris in 1704. He ſtudied aſtronomy under de l'Iſles, and in 1725 was made adjunct of the Academy of Sciences. To him was entruſted the care of editing its memoirs, and under his direction the firſt eleven volumes were publiſhed. In 1735 he was ſent, with other members of the academy, to meaſure a degree of the meridian at Peru. He was ſome time profeſſor of mathematics at Lima, and on his return in 1751, he was appointed a colonel in the Spaniſh ſervice, and director of the naval academy at Cadiz, where he died in the year 1760. He was author of ſeveral aſtronomical papers in the memoirs of the academy from 1726 to 1739: and he publiſhed “Machines et Inventions approvées par l'Academie des Sciences,” in 6 vols. 4to. “Connoiſſances des Tems,” which he conducted five years. “Cours des Mathematiques,” 1756. Gen. Biog.

GODING, or HODONING, in *Geography*, a town of Moravia, in the circle of Brunn; 16 miles E.S.E. of Auſpetz.

GODO, a town of Arabia, on the S. coaſt of the Perſian gulf; 140 miles W. of Julfar.

GODOUA, a ſmall town of Fezzan; 30 miles N. of Mourzouk, and about the ſame diſtance from Sebbah, which ſee.

GODRA, a town of Hindooſtan, and capital of a circar of the ſame name in Guzerat; 55 miles E. of Amedabad. N. lat. 22° 50'. E. long. 73° 40'.

GOD's HOUSE, *League of*, a territory of Switzerland, formerly under the dominion of the biſhop of Coire, until the people, oppreſſed by their rulers, threw off the yoke, and, forming a general league, compelled the biſhop to ratify their independence. The revolution, which finally exalted this league into its preſent ſtate of freedom, probably took place between 1424, the era of the formation of the Grey league, and 1436, the year in which the ten juriſdictions roſe into independence. This league is denominated in Romanſh “La Ligia de la Chiada,” in German “Gottſhauſband,” whence is derived the appellation of the “league of the houſe of God,” which it takes from the cathedral ſituated in its capital, as well as becauſe it was once under the juriſdiction of the biſhop of Coire. This league is divided into eleven diſtricts, each of which (Coire excepted) is ſubdivided into two little republics, or communities, and ſends 22 deputies to the general diet. Formerly the burgomaſter of Coire was perpetual chief of the league without election; but in the latter end of the 17th century the other communities claimed a power of nominating to this office in their turn. At length, by the arbitration of Zuric, it was decided, that the 22 deputies ſhould chuſe two candidates from the members of the ſenate of Coire, who ſhould draw lots for the charge. The chief thus appointed is called “Bunds-preſident,” has ſeveral privileges which diſtinguiſh him from the chiefs of the two other leagues; he receives all the letters addreſſed to the republic of the Griſons from foreign powers, and is perpetual preſident of the congreſs, becauſe that aſſembly is always held at Coire. See COIRE.

The league of God's houſe is divided into 11 high juriſdictions, and comprehends 21 communes.

High Juriſdictions.		Communities.	Members of General Diet.

God's *Mercy, Iſlands of*, three or four ſmall iſlands at the N.W. extremity of Hudſon's ſtraits. N. lat. 63° 45. W. long. 73°.

GODWIN, Earl, in *Biography*, a powerful Saxon baron, was the ſon of Wolfnoth, governor of Suſſex, and he himſelf, at the acceſſion of Canute, was earl of Kent, and lord of very great poſſeſſions. When the Daniſh poſſeſſions of Canute were attacked by the king of Sweden, Canute took over as auxiliaries a body of Engliſh commanded by the earl of Godwin, who obtained a complete victory, which ſo delighted the king, that he beſtowed his daughter in marriage upon him, made him large grants of land, and admitted him to the cloſeſt confidence. After the death of Canute, the ſucceſſion being diſputed between Harold Harefoot and Hardicanute, Godwin eſpouſed the part of the latter, and was inſtrumental in preventing a civil war. It is reported that he afterwards concurred with Harold, in a plan for deſtroying the two Engliſh princes, ſons of Ethelred II. and Emma, and the murder of one of them, *viz.* Alfred, is imputed to the vaſſals of Godwin. In the reign of Hardicanute the ſurviving prince Edward preferred an accuſation againſt the earl for the murder of his brother, and loudly demanded juſtice for the crime; Godwin, to appeaſe the king, made him a preſent of a galley finely gilt and decorated, rowed by fourſcore men, each of whom wore on his arm a gold bracelet, weighing ſixteen ounces, and they were all armed and clothed in the moſt ſumptuous manner. Hardicanute, delighted with the ſpectacle, forgot his brother's murder, and on Godwin's own teſtimony he was allowed to be acquitted. In 1041, he was ſo completely reconciled to Edward, that on the death of Hardicanute he was the chief inſtrument of promoting him to the ſucceſſion of the crown: he now acquired much influence in the ſtate, and was created duke of Weſſex, and the counties of Kent and Suſſex were annexed to his government. The friendſhip between Godwin and the king was not of long continuance. Upon his refuſal to act againſt the inhabitants of Dover, who had incurred Edward's diſpleaſure, he was threatened with the royal vengeance. The earl, feeling his own power, actually excited a rebellion againſt his ſovereign. Edward now ſummoned to his aid the dukes of Northumberland and Mercia, and being thereby ſuperior to Godwin and his ſons, he marched to London and ſummoned a great council to paſs judgment upon the rebels. Godwin, with three of his ſons, took refuge with Baldwin earl of Flanders, while Harold and another fled to Ireland. Godwin, after many misfortunes, failed with a powerful force to London, and forced the king to an accommodation: Edward conſented to baniſh his Norman favourites, who had been, in a great meaſure, the cauſe of the diſcontents, and Godwin and his ſons were reſtored to their eſtates, and the high offices which they had formerly held. Godwin's death, which happened ſoon after this, while he was ſitting at table with the king, prevented him from making farther inroads on the ſovereign's authority, or from reducing him to ſtill greater ſubjection. He was ſucceeded in the government of Weſſex, Suſſex, Kent, and Eſſex, and in the office of ſteward of the houſhold, by his ſon Harold, who was actuated by an ambition equal to that of his father, and was ſuperior to him in addreſs, in inſinuation, and in virtue. With reſpect to Godwin, his character is blackened by the monkiſh hiſtorians, who pretend that his ſudden death was the effect of a miraculous interpoſition from heaven. With great abilities, Godwin poſſeſſed an ambitious ſpirit, which rendered him a ſubject of wavering fidelity, and made him but little ſcrupulous in means that tended to his aggrandizement. Hume's Hiſt. vol. i. Biog. Brit.

Godwin, Thomas, was born at Oakingham, in Berkſhire, in 1517, where he received at the free-ſchool the elements of a learned education. His rapid proficiency in grammar-learning attracted the notice, and ſecured to him the patronage of Dr. Layton, archdeacon of Bucks, who received him into his houſe, and took care of his farther inſtruction. In 1538, he was ſent by his friend and patron to Magdalen college, Oxford: here he purſued his ſtudies, and in 1543 he took his degree of B. A. and in the following year he was elected fellow of his college, which rendered him independent of the pecuniary aſſiſtance of his friends. His ſteady regard to the principles of the reformation rendered his ſituation at college in many reſpects very uneaſy, and he gladly embraced the opportunity of a vacancy in the maſterſhip of the free-ſchool of Brackley in Northamptonſhire, which was in the gift of the college, to reſign his fellowſhip. He retired to this ſituation in 1549, and having married, continued there peaceable and happy during the reign of king Edward, devoting what time he could ſpare from the duties of his office to the ſtudy of theology and phyſic, and on the acceſſion of Mary, he became an object of Bonner's fury, and was obliged to reſign his ſchool, and turn his attention to phyſic. By the practice of this, he maintained his family till Elizabeth aſcended the throne. He now reſolved to follow the bent of his inclination, devoted his whole time to theological ſtudies, was admitted to holy orders, and appointed chaplain to the biſhop of Lincoln. He was ſhortly after introduced to the queen, who made him one of the Lent preachers. This poſt, which was probably attended with little emolument, he filled eighteen years, with very high reputation, during which he received no preferment in the church; but, in 1565, he was promoted to the deanery of Chriſt-church, Oxford, and in the ſame year a prebend was conferred on him. In 1566, he was advanced to the deanery of Canterbury, and attended the queen in her viſit to the univerſity of Oxford, on which occaſion he took his degree of D D. with great applauſe. In 1584, after eighteen years reſidence at Canterbury, he was nominated by the queen to the vacant ſee of Bath and Wells. This honour did not augment the happineſs of Dr. Godwin: in reſiſting the unjuſt claims of one of Elizabeth's favourites, he loſt the favour of the queen herſelf, which ſo affected his mind, as to render him incapable of performing his epiſcopal functions. The affairs of his dioceſe, being left to the management of others, fell into ſuch diſorder, that his metropolitan, archbiſhop Whitgift, thought proper to viſit it in the year 1587. At this time Dr. Godwin's health was in a very bad ſtate, and he gradually became worſe till he ſunk under the effects of diſeaſe, in his ſeventy-third year. He is highly ſpoken of for learning and unaffected piety, and was beloved and reſpected for his cheerful hoſpitality, benevolence, and charity. Biog. Brit.

Godwin, Francis, the ſon of the preceding, was born at Havington, in Northamptonſhire, in the year 1561, and having been carefully educated in grammar learning, he was ſent to Chriſt-church college, Oxford, when he was in his ſixteenth year, and in 1578 he was elected a ſcholar of that inſtitution. In 1580, he took his degree of B. A., and three years after he proceeded to his degree of M.A. About this time he wrote an entertaining philoſophical fiction, which he did not at that period publiſh, becauſe it contained ideas at variance with the ſyſtems then prevalent in the ſchools. It was given to the world five years after his death, under the title of "The Man in the Moon, or a Diſcourſe of a Voyage thither by Domingo Gonzales." The hints, conjectures, &c. contained in this piece, prove that the author was not ignorant of the writings of Copernicus, and was probably a convert to his doctrines. In 1587, he was a canon in the cathedral church of Wells, and promoted to the ſubdeanery of Exeter. The hiſtory and antiquities of his country became favourite ſubjects of his enquiries, and in the year 1590 he accompanied the celebrated Camden into Wales, in ſearch of objects to illuſtrate them. In 1595, he took the degree of doctor in divinity, being in poſſeſſion of very conſiderable and lucrative preferment in the church. He publiſhed, in 1601, "A Catalogue of the Biſhops of England, ſince the firſt Planting of the Chriſtian Religion in this Iſland, together with a brief Hiſtory of their Lives and memorable Actions, ſo near as can be gathered out of Antiquity." As a reward for the great diligence uſed in the compoſition of this catalogue, the queen promoted him, the ſame year, to the vacant ſee of Landaff; being allowed to retain, in connection with the biſhopric, the ſubdeanery of Exeter, and a good rectory in the dioceſe of Bath and Wells. He now employed himſelf in improving his "Catalogue," and in making collections relative to civil and eccleſiaſtical hiſtory. In 1615 he publiſhed a new edition of his "Catalogue," to which he prefixed a diſcourſe "Concerning the firſt Converſion of our Britain unto the Chriſtian Religion." It was afterwards republiſhed in Latin, under the title of "De Præſulibus Angliæ Commentarius." In the ſame year he publiſhed "Rerum Anglicarum Henrico VIII., Edwardo VI., et Maria, regnantibus, Annales," which was much admired for the elegance of the ſtyle. By king James he was tranſlated from Landaff to the biſhopric of Hereford in the year 1617, and from this period, he devoted ſuch time as the diſcharge of his epiſcopal functions would permit, chiefly to the improvement of his former works; but in 1629 he publiſhed a diſcourſe on the ſeveral methods of conveying ſecret and ſpeedy intelligence, with the title of "Nuncius Inanimatus, Utopia." It has been ſuggeſted that this was written in obſcure and enigmatical language, with a deſign of concealing the author's ſecret; but from certain expreſſions, it ſhould ſeem, that the hints contained in it might have led to an earlier eſtabliſhment of public telegraphs. Beſides ſeveral editions of the Annales, and a tranſlation into Engliſh of the ſame work, we have a learned diſſertation by the biſhop, on the value of the Roman ſeſterce and attic talent, which was printed at the end of Hakewell's "Apology of Divine Providence." This was his laſt labour in the field of literature. He died in 1633 in his ſeventy-ſecond year. Of his learning and claſſical taſte, his works bear moſt deciſive evidence, and they exhibit him as a zealous friend to the eſtabliſhment, of which he was a member. According to Anthony Wood, "he was a good man, a grave divine, a ſkilful mathematician, an excellent philoſopher, a good preacher, and a ſtrict liver; but ſo much employed in his ſtudies and matters of religion, that he was a ſtranger to the world and the things thereof." Biog. Brit.

Godwin, Thomas, a learned Engliſh divine and writer on Jewiſh antiquities, was born in Somerſetſhire in the year 1587. In his fifteenth year, he was ſent from the grammar-ſchool to Magdalen-hall, in the univerſity of Oxford, where he was entered a ſcholar. Here, in due courſe, he took his degrees, and ſoon after was choſen maſter of the free-ſchool at Abingdon, in Berkſhire. In this ſituation he diſtinguiſhed himſelf by his diligence and aſſiduity in forming good ſcholars, who afterwards became eminent in various departments of literature, and in poſts of honour and emolument in the church and ſtate. In 1613 he publiſhed "Romanæ Hiſtoriæ Anthologia,"—an Engliſh expoſition of the Roman antiquities, which went through ſeveral editions. Shortly after this, he entered into orders, and was appointed chaplain to Dr. James Montague, biſhop of Bath and Wells, and in 1616 he was admitted to the degree of bachelor of divinity, and publiſhed a work, entitled "Synopſis Antiquitatum Hebraicarum ad Explicationem utriuſque Teſtamenti valde neceſſaria, &c." lib. 3. 4to. About this period he reſigned his ſchool, upon obtaining a preſentation to the rectory of Brightwell, near Wallingford, in Berkſhire. In the year 1625, he publiſhed the work by which he is chiefly known, *viz.* "Moſes and Aaron; civil and eccleſiaſtical Rites, uſed by the ancient Hebrews, obſerved, and at large opened, for the clearing of many obſcure Texts, throughout the whole Scripture." This work was immediately regarded as a ſtandard book in our places of academical education, and has been repeatedly printed. In 1636, Mr. Godwin was admitted to the degree of doctor of divinity. He died in 1642. Beſides the works already noticed, Dr. Godwin was the author of "Florilegium Phraſicon,"—or A Survey of the Latin Tongue. And Three Arguments to prove election upon foreſight of faith. Gen. Biog.

Godwin, or *Goodwin Sands*, in *Geography*, a bank in the ſea, about five miles from Deal, near the coaſt of Kent, England, were formerly part of the eſtate of the celebrated earl Godwin, but were ſeparated and overwhelmed by a ſudden inundation of the ſea, about the end of the eleventh century. Theſe ſands are frequently fatal to mariners, but, notwithſtanding, are of conſiderable uſe, as it is by them alone that the Downs are conſtituted a road or harbour for ſhipping. In all eaſterly winds they ſerve as a pier, or break-water, and greatly mitigate the force and immenſity of the waves, which, in ſtormy weather, would otherwiſe roll upon this ſhore with unabated fury. The ſands extend in length about ten miles; the north ſand-head being nearly oppoſite to Ramſgate, and the ſouth ſand-head to Kingſdown. The danger of ſtriking upon them ariſes from their nature, which Mr. Smeaton deſcribes as that of a quick-ſand, clean and unconnected, yet lying ſo cloſe, as to render it difficult to work a pointed bar to the depth of more than ſix or ſeven feet. Their ingurgitating property is ſo powerful, that even the largeſt veſſel driven upon them would, in a few days, be ſwallowed up, and ſeen no more. At low-water they are in many parts dry, and parties frequently land upon them; but when the tide begins to flow, the ſand becomes ſoft, and is moved to and fro by the waves. The largeſt portion of this bank which becomes dry, is known to ſeamen by the name of the Jamaica iſland. Some years ago, in order to prevent the many accidents which occur to ſhipping on theſe ſands, the Corporation of the Trinity-houſe formed the deſign of erecting a light-houſe on them; but after the ſand had been penetrated by boring augers to a great depth, the ſcheme was given up as impracticable, as no ſolid foundation could be obtained. Floating lights have, however, been placed off theſe ſands, conſiſting of three diſtinct lights in the form of a triangle, of which the middle one is conſiderably the higheſt; when they are obſcured in hazy-weather, a bell is kept conſtantly ringing.

Godwit, *Great*, or *American*. See Scolopax *Fedoa*.

Godwit, *Leſſer*. See Scolopax *Limoſa*.

Godwit, *Red*. See Scolopax *Lapponica*.

Godwit, *White*. See Recurvirostra *Alba*.

GOELANS, Point au, in *Geography*, a promontory on the N. ſide of lake Ontario; about 33 miles S. W. of fort Frontinac.

GOELHEIM, a town of France, in the department of Monte Tonnerre, and chief place of a canton, in the diſtrict of Kaiſerſlautern. The place contains 860, and the canton 4999 inhabitants, in 16 communes.

GOELICKE, Andrew Otton, in *Biography*, a German phyſician, who acquired conſiderable reputation at the beginning of the eighteenth century, and taught the ſcience of medicine at Halle, in Saxony, and at Franckfort on the Oder, with diſtinction. His writings were in high eſtimation among the followers of the doctrines of Stahl, of whom he was one of the ableſt defenders. Nothing more is known reſpecting his life. He left ſeveral works, which relate principally to the hiſtory of anatomy, of ancient and modern ſurgery, and of medicine. His "Hiſtoria Medicinæ Univerſalis, quâ celebriorum quorumcunque Medicorum, qui a primis Artis natalibus ad noſtra uſque tempora inclaruerunt, vitæ, nomina, dogmata ſingularia, ratiocinia, hypotheſes, ſectæ, &c. accurate pertractantur," was printed in ſix different portions or epochs, between the years 1717 and 1720. The firſt four brought down the hiſtory to Hippocrates; the fifth treated of the Hippocratic medicine alone; and the laſt part included a ſketch of the deſcendants of the father of medicine, until the time when the art was divided into three profeſſions. Eloy. Dict. Hiſt.

GOELL, in *Geography*, an iſland of Denmark, in Lymford gulf, about 10 miles in circumference; on which are a town and a village or two; 6 miles W. of Aalborg. N. lat. 57° 5′. E. long. 9° 49′.

GOELMA, a port of Egypt, in the Red ſea, capable of accommodating only ſmall veſſels.

GOELWARA, a circar of Hindooſtan, in Guzerat, on the W. coaſt of the gulf of Cambaye.

GOEREE, William, in *Biography*, who flouriſhed in the 17th century, was born at Middleburg, in Zealand, in the year 1635. He had a decided turn for literature, but by the death of his father while very young, he was conſigned to the care of an illiterate ſtep-father, who would not permit him to purſue the bent of his mind. Being obliged to fix upon a trade, inſtead of ſtudying for one of the learned profeſſions, he fixed on that of a bookſeller, as that which he imagined beſt adapted for the improvement of his leiſure hours in the acquiſition of knowledge. His various works will ſhew how well he filled his time, and to what advantage he turned thoſe intervals from occupation, which are too frequently ſpent in liſtleſſneſs or devoted to pleaſure. He died at Amſterdam in 1711, leaving his "Jewiſh Antiquities," in two volumes, folio. "The Hiſtory of the Jewiſh Church," in four volumes folio. "Hiſtory Sacred and Profane." "An Introduction to Painting." "A Treatiſe on Architecture;" and ſome other uſeful works. Moreri.

GOERZEOD Ghezere, in *Geography*, a town of Aſiatic Turkey, in Natolia; 25 miles S. of Sinob.

GOES, a town of Portugal, in the province of Beira; 9 miles E. of Coimbra.—Alſo, a town of Holland, in Zealand, called "Ter-Goes," ſituated on the N. coaſt of the iſland of South Bevelandt, on an arm of the Scheldt, with which it is connected by means of a canal. The great church is a handſome ſtructure; and though the town is not large, it carries on a conſiderable trade, particularly in ſalt and grain; 10 miles E. of Fluſhing. N. lat. 51° 33′. E. long. 3° 46′.

GOETIA, Γοητεία, a ſpecies of magic, oppoſed to Theurgia, the object of which was miſchief; and accordingly it invoked only the malevolent genii.

GOEZ, Damiana, in *Biography*, a learned Portugueſe, of the 16th century, was born at Alenquer, and educated in the court of the king Emanuel, to whom his brother was gentleman of the chamber. He was, as he advanced in life, employed in various negociations from his court to the court of France, Germany, Poland, and the Low Countries. In 1534, we find him at the univerſity of Padua, in which he ſtudied ſome years under Buonamico, and contracted a friendſhip in Italy with Bembo, Sadolet, and other great men. He carried forward his ſtudies at Louvain, where he fixed his reſidence after his marriage, and was the principal means of defending the city againſt the attack of Martin van Roſſem. He was, however, ſeized by the enemy, under the pretence of a violation of the truce, and obliged to ranſom himſelf. He was after this recalled by the king of Portugal, who wiſhed to employ him to write the hiſtory of that country. The materials put into his hands were in ſo confuſed a ſtate, and ſo ſcanty in regard to quantity, that he was able to perform but a ſmall part of the taſk. He was malignantly accuſed, arreſted, and thrown into priſon. At length, as there was nothing found againſt him, he was liberated, and returned ed to his own dwelling, where he was ſhortly after found burnt to death, the conſequence, probably, of an apoplectic fit. His works are, " Legatio magni Indorum Imperatoris ad Emanuelem Luſitaniæ Regem." " Fides, Religio, Moreſque Æthiopum." " Hiſpaniæ Laudatio." " Urbis Lovanienſis Obſidio." " Comment Rerum Geſtarum in India à Luſitanis." " Urbis Ulyſſiponenſis Deſcriptio." " Hiſtoria del rey Dom. Manuel." " Chronica de Principe D. Juao II." Moreri.

GOEZE, John Augustus Ephraim, was born at Aſcherlen in the year 1731, where he received the elements of a learned education. He was afterwards ſent to Halle to purſue his ſtudies preparatory to the exerciſe of the profeſſion of preacher. In 1751 he ſettled in that capacity at Quedlingburg, which he retained till the period of his death. It was not till he was about forty years of age that he turned his attention to the microſcope and natural hiſtory, for his ſkill in which he afterwards became ſo famous. At firſt he made uſe of his microſcope only for amuſement, but in a ſhort time he poſſeſſed himſelf of the very beſt inſtruments of the kind that had been manufactured, and his reſearches led him to the ſtudy of the natural hiſtory of inſects. Baker's deſcription of certain water inſects induced him to explore the ditches, rivulets, and ponds. He wrote down his obſervations for his own private uſe, and cauſed many of the objects which he ſaw to be delineated. The facts thus collected he publiſhed in the Hanoverian magazine, which attracted the notice of the learned, from whom he received many flattering and highly complimentary letters on the ſubject. He tranſlated Bonnet's treatiſe on inſectology, which met with a very favourable reception from naturaliſts. He ſet out without regard to ſyſtem or order, but ſoon found that ſyſtematic knowledge was neceſſary in his purſuits; and completely acquainted himſelf with the Linnæan arrangement; and his " Entomological Collections" were intended as a ſupplement to the works of the Swediſh naturaliſt. The next conſiderable work of Goeze was on the natural hiſtory of inteſtinal worms, which he publiſhed in quarto in 1782. This work contributed greatly to encreaſe his reputation as a naturaliſt, and entitles him to an honourable place among the diſcoverers of modern times. The intereſt which he took in the education and improvement of his own children led him to publiſh ſome works on natural hiſtory, intended particularly for young perſons in general, and being a very agreeable as well as learned writer, his productions were all well received, and to his honour it muſt be ſpoken that he never forgot to inculcate the duties of religion and morality while he was deſcanting on the wonders of the natural world. After he had communicated to the public the reſult of his obſervations on inteſtinal worms, he ſent his collection to Pavia, where it was ſold for a thouſand dollars. His fame, however, had extended much beyond his own country, and within a very few weeks after he had parted or at leaſt agreed to part with his curious collection for the above named price, he received a letter from Dr. Hunter, offering him nearly double the ſum for it. He died in June 1786. Gen. Biog.

GOFABAD, in *Geography*, a town of Perſia, in the province of Irak: 55 miles E. of Iſpahan.

GOFFE. See Geoff.

GOFFSTOWN, a town of America, in Hillſborough county, New Hampſhire, ſituated on the weſtern bank of Merrimack river, 3 miles from Amuſkeag falls, or 60 miles W. of Portſmouth. It was incorporated in 1761, and contains 1612 inhabitants.

GOG and Magog, in *Scripture Hiſtory*, are names generally connected in the ſacred writings. (See Ezek. xxxviii. 2, 3, &c. xxxix. 1, 2, Rev. xx. 8.) Moſes (Gen. x. 2.) ſpeaks of Magog, the ſon of Japheth, but ſays nothing of Gog. According to Ezekiel, (ubi ſupra,) Gog was prince of Magog; the latter ſignifying the country or people, and the former, the king of it. The ancients generally repreſent Magog as the father of the Scythians or Tartars; and traces have been found of the name in the provinces of Great Tartary. Others ſay that the Perſians are deſcendants of Magog; and to this purpoſe people have been found there called Maguſians, and philoſophers called Magoi or Magi. Some have imagined that the Goths were deſcended from Gog and Magog: and that the wars deſcribed by Ezekiel, and undertaken by Gog againſt the ſaints, are thoſe which the Goths carried on, in the 5th century, againſt the Roman empire. Bochart has placed Gog in the vicinity of Caucaſus; and he derives the name of this celebrated mountain from the Hebrew גוג חסן, gog-chaſan, the fortreſs of Gog. He alſo ſays, that Prometheus, ſaid to be chained to Caucaſus, is Gog; and it may be obſerved, that there is a province in Iberia S. of Caucaſus, called the Gogarene. Moſt perſons are of opinion, that Gog and Magog, in Ezekiel and the Revelations, are taken, allegorically, for ſuch princes as were enemies to the church. Accordingly many, by Gog in Ezekiel, underſtand Antiochus Epiphanes, the perſecutor of the Jews; and Gog in Revelations, they ſuppoſe to repreſent Antichriſt. Calmet apprehends that the Gog of Ezekiel and Cambyſes, king of Perſia, were the ſame perſons. The Arabians are of opinion that the deſcendants of Gog and Magog inhabit the northern parts of Aſia, beyond the Tartars and Sclavonians: and hence it is probable that Gog and Magog, according to the notions of the Arabians, formerly inhabited the mountains of the Hyperboreans, and that they were known to the ancients by this name. This nation is unqueſtionably famous in antiquity, and there is reaſon for imagining, that they were ſome of the Scythians, and confounded among the Great and Little Tartars, and perhaps among the Muſcovites, and other northern people. Calmet.

Gog-Magog *Hills*, in *Geography*, hills ſo called, about three miles from Cambridge, remarkable for the intrenchments and other works found there, and ſuppoſed by ſome to be a Roman camp, and by others, a work of the Danes.

GOGA, a town of Abyſſinia; 30 miles S. of Gondar.—Alſo, a ſmall town of India, on the weſtern ſide of the gulf of Cambaya, about 28 or 30 leagues from Cambaya, abounding with banians and ſea-men.

GOGARD, a town of Sweden, in Eaſt Gothland, 23 miles N.N.W. of Linkioping.

GOGARENA, in *Ancient Geography*, a country of Aſia, in Armenia. Strabo.

GOGARY, in *Geography*, a town of Bengal; 24 miles N.W. of Boglipour. N. lat. 25° 26′. E. long. 86° 36′.—Alſo, a town of Hindooſtan, in Bahar; 10 miles N. E. of Monghir.

GOGAVINUS, Antonius Graviensis, or Anthony Gogavin de Grave, in *Biography*, a laborious writer, who, according to the inſinuations of the famous Zarlino, publiſhed *in corpo* all the ancient authors on muſic, at Venice, 1562, 4to.

His compilation contains the books of Ariſtoxenus and Ptolemy, and the fragment of Ariſtotle, with the Commentary of Porphyry, the whole enriched with notes by Bottrigari. See Meibomius, and Bottrigari.

GOGET, in *Ichthyology*. See Gobius *Niger*.

GOGGLES, in *Rural Economy*, a morbid affection in ſheep, which is ſometimes extremely deſtructive to them. It is ſuggeſted in the Bath papers as firſt ſhewing itſelf, by a dropping of the ears, and frequent rubbing of the tail; but not to have any relation or affinity to giddineſs, as the ſheep do not run round as in that diſeaſe. It appears to have the greateſt reſemblance to the diſorder called the ſtaggers in lambs; but differs inſomuch, as that the ſtaggery lambs diſplay weakneſs before, and of courſe fall in that direction, while the goggly ſheep ſhew weakneſs behind, and when forced to run fall backwards. Sheep under this diſorder conſtantly get poorer and poorer, and become more weak, until they are not able to drag their limbs after them, and conſequently die. Some have contended that it is a diſeaſe of the paralytic kind, and that the ſeat of the complaint is in the ſpinal marrow. It was formerly either wholly unknown, or unattended to by ſheep-farmers, as it is never mentioned.

Hitherto no ſatisfactory method of cure has been pointed out for the diſeaſe, but warmth and frequent change of paſture have been found beneficial in it.

GOGGLES, in *Surgery*, are inſtruments uſed for curing ſquinting, or that diſtortion of the eyes which occaſions this diſorder. They are ſhort conical tubes, compoſed of ivory ſtained black, with a thin plate of the ſame ivory fixed in the tubes near their anterior extremities. Through the centre of each of theſe plates is a ſmall circular hole, about the ſize of the pupil of the eye, for the tranſmiſſion of the rays of light. Theſe goggles muſt be continually worn in the day-time, till the muſcles of the eye are brought to act regularly and uniformly, ſo as to direct the pupil ſtraight forwards; and by theſe means the cure will be ſooner or later effected. Warner on the Eye, p. 32.

GOGMOW, in *Geography*, a town of Hindooſtan, in Oude; 35 miles N. of Maniakpour.

GOGO. See GOGA.

GOGODUNGA, a town of Bengal, on a ſmall iſland formed by a branch of the Hoogly; 45 miles S. of Calcutta.

GOGOROMOW, a town of Guzerat, on the coaſt; 50 miles W. S. W. of Noanagur.

GOGRA, alſo called *Dewah* and *Soorjew*, a river of Hindooſtan, which proceeds from a lake named Lanke-Dhe, having to the E. of it another larger lake, named Manſawar, both ſituated on the weſtern ſide of Thibet, and forces its way through the vaſt ridge called Himmaleh, and afterwards joins the Ganges. See DEWAH.

GOGUET, ANTONY-YVES, in *Biography*, was born at Paris in 1716, where his father was an advocate. He himſelf became a counſellor to the parliament. By cloſe ſtudy and by great aſſiduity in his purſuits, he produced in the year 1758, a work that has obtained a high reputation, and which has been tranſlated into the Engliſh and other languages. It is entitled "Origine des Loix, des Arts, des Sciences, et de leur Progrès chez les anciens Peuples," in three volumes 4to. It was printed in 1778, in ſix volumes 12mo. This work treats of the origin and progreſs of human knowledge, from the creation to the age of Cyrus, and diſplays much erudition in hiſtorical diſcuſſions, though leſs of ſcience and philoſophy than might have been expected. He died of the ſmall-pox almoſt immediately after the publication of this valuable work. He was a man of much private worth, modeſt and unaſſuming. He had begun another work on the Origin and Progreſs of the Laws, Arts, Sciences, &c. in France, from the commencement of the monarchy.

GOHANNA, in *Geography*, a town of Hindooſtan, in Ballogiſtan; 54 miles W.S.W. of Delhi.

GOHEE, a town of Hindooſtan, in Bahar; 35 miles W.N.W. of Saſeram.

GOHUD, a circar of Hindooſtan, in the ſoubah of Agra, lying on the right ſide of the river Jumnah. It is bounded on the N. by the Chumbal, on the E. by Dooab and Oude, on the S. by Bundelcund, and on the W. by Rantampour and Cottah.—Alſo, a town of this circar, the revenues of which are eſtimated at 20 or 30 lacks of rupees per annum; 55 miles S. E. of Agra. N. lat. 26° 24′. E. long. 78° 44′.

GOJAK, a town of Croatia, on the river Mreſnitza; 18 miles S. of Carlſtadt.

GOJAM, a province of Abyſſinia, about 80 miles in length, and 40 in breadth. It is a very flat country, altogether appropriated to paſture; it has few mountains, but theſe are very high, and are chiefly on the banks of the Nile, to the ſouth, which river ſurrounds the province. Gojam is full of great herds of cattle, which are the largeſt in the high parts of Abyſſinia. The country is populous, but the men are in the loweſt eſtimation as ſoldiers. The Jeſuits were ſettled in many convents throughout the province, and are held in the utmoſt deteſtation. The monks are thoſe of St. Euſtatius, which may be called the Low Church of Abyſſinia; they are ſaid to be much inclined to turbulence in religious matters, and are, therefore, always made tools by diſcontented people who have no religion at all. On the S.E. of Gojam is Damot; which ſee. Bruce.

GOJAS. See GOYAS.

GOIAVA, a town of Africa, on the Grain coaſt; 25 miles S.E. of Grand Seſto.

GOJEIDA, or GOGIDA, a town of Algiers; 90 miles S.E. of Oran.

GOING, in the *Manege*, called in French *allure*, is the pace or gait of a horſe.

GOIT, GURT, *Gorl*, *Leat*, &c. are names for a ditch or trench for conveying water, uſed by engineers and miners of different diſtricts.

GOITO, in *Geography*, a town of Italy, in the department of the Mincio, ſituated on the river Mincio, between the lake of Mantua and that of Garda; 9 miles N.N.W. of Mantua.

GOITRE, or GOUTIER, in *Surgery*, names ſometimes applied to a morbid enlargement of the thyroid gland. See BRONCHOCELE.

Perſons labouring under this complaint are found in various mountainous diſtricts of Europe, in China, in Bootan, and many other regions of the Eaſt, in Sumatra, &c. (See CRETINS.) Turner, in his "Account of an Embaſſy to Tibet," ſays, that in Bengal this unſightly tumour is known by the name of "Gheig," and "Aubi," and in Bootan is called "Bà," or "Ke Bá," the neck-ſwelling, and that it forms itſelf immediately below the chin, extending from ear to ear, and ſometimes growing to ſuch an enormous ſize, as to hang from the throat down upon the breaſt. It is particularly obſervable, he ſays, among the inhabitants of the hills of Bootan, immediately bordering upon Bengal, and in the tract of low country watered by the rivers that flow from them to the ſouth, beyond the ſpace of a degree of latitude. The ſame malady prevails among the people inhabiting the Morung, Nipal, and Almora hills, which, joined to thoſe of Bootan, run in continuation, and bound, to the northward, that extenſive tract of low land embraced by the Ganges and the Berhampooter. The ſame diſeaſe is alſo more particularly met with in the low lands adjoining to theſe hills. From the frontier of Aſſam, N. lat. 27°. E. long. 91°, it is to be traced through Bijnee, Gooch Bahar, Rungpore, Dinagepore, Purnea, Tirrooto, and Betiah, along the northern boundary of Oude, in Gooracpore, Barraitch, Pillibeat, and on the confines of Rohilcund, to Hurdewar, ſituated in N. lat. 30°. E. long. 78° 25′. It has the effect, he adds, or rather is accompanied with the effect, ariſing from the ſame cauſe, of debilitating both the bodies and the minds of thoſe who are affected with it. Marſden, in his "Hiſtory of Sumatra," obſerves, that it has been uſual to attribute this affection to the badneſs, thawed ſtate, mineral quality, or other peculiarity of the waters: "My experience," he adds. "enables me to pronounce without heſitation, that the diſorder, for ſuch it is, though it appears here to mark a diſtinct race of people, *(orang goonong,)* is immediately connected with the hillineſs of the country, and, of courſe, if the circumſtances of the water they uſe contribute thereto, it muſt be only ſo far as the nature of the water is affected by the inequality or height of the land. But in Sumatra neither ſnow nor other congelation is ever produced, which militates againſt the moſt plauſible conjecture that has been adopted concerning the alpine goitres. From every reſearch that I have been enabled to make, I think I have reaſon to conclude, that the complaint is owing, among the Sumatrans, to the foggineſs of the air in the vallies, between the high mountains, where, and not on the ſummits, the natives of theſe parts reſide. I before remarked, that between the ranges of the hills, the "caboot," or denſe miſt, was viſible for ſeveral hours every morning; riſing in a thick, opaque, and well-defined body, with the ſun, and ſeldom quite diſperſed till afternoon. This phenomenon, as well as that of the wens, being peculiar to the regions of the hills, affords a preſumption that they may be connected; excluſive of the natural probability that a cold vapour, groſs to an uncommon degree, and continually enveloping the habitations, ſhould affect with tumours the throats of the inhabitants. I cannot pretend to ſay how far this ſolution may apply to the caſe of the goitres, but I recollect it to have been mentioned, that the only method of curing theſe people is by removing them from the vallies to the clear and pure air on the tops of the hills; which ſeems to indicate a ſimilar ſource of the diſtemper with what I have pointed out. The Sumatrans do not appear to attempt any remedy for it, the wens being conſiſtent with the higheſt health in other reſpects."

GOKAUP, in *Geography*, a town of Hindooſtan, in Viſiapour; 16 miles S.S.E. of Raiboug.

GOKIA, a town of Turkiſh Armenia; 30 miles E.S.E. of Akalziké.

GOLABAD, a town of Perſia, in the province of Irak; 45 miles E. of Iſpahan.

GOLAH, a town of Hindooſtan, in Bahar; 10 miles E. of Ramgur.

GOLAN, a town of the duchy of Warſaw; 10 miles N.E. of Poſen.

GOLAPILLY, a town of Hindooſtan, in the circar of Guntoor; 10 miles W. of Innaconda.

GOLAWARRY, a town of Bengal; 48 miles N.W. of Midnapour.

GOLCONDA, a province of Hindooſtan, part of the poſſeſſions of the Nizam, or Soubah of the Deccan, our firm ally, correſponds to the ancient province of Tellingana, or Telling, ſituated between the lower parts of the courſes of the Kiſtnah and Godavery rivers; and is bounded on the N. by Berar, on the E. by the Circars, on the S. by the Myſore country and the Carnatic, and on the W. by Dowlatabad. and Viſiapour. It takes its name from a famous fortreſs. The kings of this country were, at a former time, immenſely rich and powerful; as they maintained in their pay 500,000 ſoldiers, and derived very large revenues from their lands, cuſtoms of merchandizes and proviſions, but chiefly from the diamond mines, for which this country has been ſingularly famous. The winter in Golconda begins in June with rain and thunder; the rain pouring down, accompanied by violent ſtorms of wind, till the middle of July, with occaſional intervals of fine weather. In Auguſt, September, and October, the rains again fall, and very much ſwell the rivers. Theſe rains render the land exceedingly fertile, particularly in fruits. Vines are plentiful, and of the grapes, which ripen in January, they make white wine. Two crops of rice are produced annually, and the country affords other kinds of grain. The capital of Golconda is Hydrabad.

GOLCONDA is alſo the name of a fortreſs, ſurrounded by ſtone walls and deep ditches, which was formerly the reſidence of the kings of the country. This fortreſs, on account of its extent, might be denominated a city; a hill roſe in the middle of it like a ſugar-loaf, and the ſides of it were encompaſſed by the king's palace, which was very large and well ſituated for air, and which had a good view of Hydrabad. When Aurungzebe conquered the kingdom of Golconda in 1687, this fortreſs was taken by treachery; the king offered to pay a tribute of 3,700,000 rupees, and become the vaſſal of the conqueror; but he refuſed, and entered the palace in triumph.

GOLD. *Gold*, Germ.; *Guld*, Swed. Dan.; *Or*, Fr.; *Arany*, Hung.; *Soloto*, Ruſſ.

Mineralogical Deſcription.—This metal never having been found in a mineralized ſtate, we are acquainted with one ſpecies only, namely,

Native gold, which is ſubdivided by Werner into three ſub-ſpecies, *viz. gold-yellow*, *braſs-yellow*, and *greyiſh-yellow gold.* Though this ſubdiviſion may appear arbitrary, and not founded on conſtant characters excluſively belonging to each of the above varieties or ſub-ſpecies, it is nevertheleſs entitled to attention, ſince colour, however unimportant it may be in the claſſification of earthy foſſils, conſtitutes a character of conſiderable value in native metallic ſubſtances, the range of whoſe colours is confined to a narrow compaſs. But alſo their geognoſtic relation appears to conſtitute a diſtinction, at leaſt between the two firſt of the Wernerian ſub-ſpecies; for as to the third, or the *greyiſh-yellow gold*, its claims to be kept ſeparate from the two others appear doubtful: all we know of it is its being found in ſmall flat particles, along with that mixture of different metals called platina in grains, of whoſe colour it partakes in general, and with which it is ſuppoſed to have occurred alſo originally under the ſame geognoſtic relations.

1. *Light or Braſs-coloured native Gold.* Meſſing-gelbes gediegen gold of Werner. Its colour is pretty well indicated by its name; but it varies in intenſity from what may be called pale-gold yellow to yellowiſh-ſilver white. It is alſo ſometimes found with deep-yellow, and with pavonine tarniſh.

It occurs maſſive, diſſeminated in angular and amorphous particles, but more frequently in films, membranes, and plates even and curled or twiſted, and with ſmooth or druſed ſurface; alſo capillary, tooth and wire-ſhaped, ſhrub and fern-like, and as moniliform ſtrings; often imitating reticulated and filigree work; all which forms are generally produced by the aggregation of minute imperfect cryſtals. Among theſe, perfect cryſtals are not unfrequently ſeen, ſometimes ſingle, oftener in groups, on the margin of the plates, &c. The following ſecondary forms have been obſerved: the cube; the octahedron; the garnet-dodecahedron; the leucite-dodecahedron with trapezoidal planes. Alſo modifications intermediate between the cube and the octahedron occur, but they are ſcarce. The minute three-ſided pyramids, which are often ſeen to druſe the membrane, and the ſimple triangular marks on the plates of the Tranſylvanian native gold, are the reſults of hurried and diſturbed cryſtallization; the former of them being the ſolid angles of the cubical, and the latter the rudiments of the octahedral variety.

. The cryſtals are minute (thoſe deſcribed by Mr. Eſmark as octohedra and cubes of two lines in diameter, have never before been heard of); their ſurface is always ſmooth.

Luſtre metallic: externally ſplendent: while that of the grains is ſometimes gliſtening, ſometimes approaching to dull; internally it is glimmering and gliſtening.

The fracture of gold is fine hackly. Its fragments are indeterminately angular.

It is ſoft, highly flexible, malleable, and ductile.

The ſpecific gravity of pure gold is from 19.253 to 19.640; but that of the braſs-yellow variety, owing to a greater proportion of ſilver with which it is alloyed, is generally conſiderably leſs, though always above twelve.

The light, or braſs-yellow gold, occurs almoſt always in veins in greywacke, greywacke ſlate, and newer porphyry; ſeldom, as the following ſub-ſpecies, in primitive rocks, or under other circumſtances that beſpeak a ſimilar remote antiquity.

It occurs chiefly with quartz and iron pyrites, and not unfrequently with grey antimony. Other concomitant ſubſtances are, among the earthy foſſils, calcareous ſpar, brown ſpar, barytes, ſelenite, and ſeldom ſmall quantities of bole, lithomarge, and common garnet; of metallic ſubſtances, red and vitreous ſilver ores, (ſeldom native ſilver,) copper pyrites, grey copper ore, copper green, brown iron ſtone, galena, green lead ore, blende, with occaſional traces of white cobalt, copper nickel, red orpiment, native arſenic, and arſenical pyrites.

2. *Deep or Gold-yellow Native Gold.*—Gold-gelbes gediegen-gold of Werner.

Its colour is the higheſt gold-colour, ſeldom verging on braſs yellow.

It occurs maſſive and in ſmall roundiſh and flattened pieces, as alſo in grains of various dimenſions, detached or diſſeminated; ſeldom in particular external forms, ſuch as in leaves and laminæ, filiform and moſslike; ſcarcely ever cryſtallized: almoſt all the cryſtalline forms deſcribed by authors belonging to the light-coloured ſub-ſpecies.

External luſtre gliſtening, ſometimes (as in the variety called Spaniſh ſnuff) diveſted of all luſtre. Its ſpecific gravity is rather greater than that of the light or braſs-coloured gold, with which it agrees in the remaining characters.

It occurs moſtly looſe, in alluvial ſituations, and in the ſand of rivers, and, as ſuch, appears to have been originally diſſeminated in rocks of ancient formation: it is, however, alſo found in veins in Norway, Siberia, Bohemia, Hungary, in the Eaſt Indies, &c. almoſt always diſſeminated in quartz, accompanied by iron-pyrites; but nothing is as yet known reſpecting the age of theſe veins. At Fatzebay it is found in minutely moſslike external forms, often of a dull powdery appearance, on common quartz ſometimes mixed with iron pyrites; in this ſtate it is by the miner called Spaniſh ſnuff.

Geographical ſituation.—The following localities comprehend both the ſub-ſpecies into which native gold is divided by Werner. By far the greater part of that found in Europe belongs to the braſs-yellow ſub-ſpecies, except the gold of rivers and alluvial ſoil, which is principally deep yellow, and to which the immenſe quantities of this precious metal, furniſhed by the other parts of the world, appear likewiſe to be referable.

Europe:—Hungary, the Bannat, and principally Tranſylvania. In Upper Hungary it occurs in gneiſs: at Schemnitz, in Lower Hungary, it is found accompanied with ſeveral ſilver ores, and with galena; at Kremnitz, in and on cellular and ſhattered quartz, lamellar barytes, with vitreous ſilver and grey copper ore, copper pyrites, brown ſpar, &c.; at Oravizza, in the Bannat, it occurs filiform and diſſeminated in pale fleſh-red and greeniſh-white limeſtone, with white cobalt ore and copper nickel. In Tranſylvania, the richeſt country of Europe in this metal, it principally occurs in a kind of clay-porphyry of different degrees of freſhneſs, which is the Saxum metalliferum of Born, in grauwacke and grauwacke ſlate: at Kapnik it is ſometimes found with red orpiment: at Staniſha in calcareous ſpar, mixed with arſenical pyrites, &c.: other places of Tranſylvania abounding in gold (which is for the greater part braſs-yellow), are Vereſhpatak, Abrudbanya, Boiza, Offenbanya, Fatzebay, Toplitza, Treſhtyan, &c. Alſo the rivers, both of Hungary and Tranſylvania, are richly auriferous; gold ſand is found in the Nera, and underneath a ſtratum of chalk on the plain traverſed by this river. The richeſt river of Tranſylvania is the Araniosh, and the plain bordering on the river Moroſh, contains likewiſe gold in grains, between a ſtratum of mould, and another of ſchiſtus, neither of which ſtrata is in the leaſt auriferous. Alſo at Olapian, gold is obtained by waſhing; it is there mixed with magnetic ironſtone, titanium, garnet, and cyanite. The gold of the great rivers of Tranſylvania is generally of 21 carats, that of Olapian and Roſhinar is even of 23 carats, ſix grains.

In Germany it is found in ſeveral places, at Johangeorgenſtadt in Saxony, in Carinthia, where it accompanies copper-ores, in Tyrol and Saltzburg; but it is only in the laſt of theſe diſtricts, or rather in the chain of mountains, ſeparating Tyrol from Carinthia, that gold-mines are worked: in the Zillerthal it is found in various external forms, and accompanied with iron-pyrites, &c. in mica ſlate. In Bohemia gold occurs in quartz.

Spain is probably very rich in gold; certain it is that conſiderable gold mines were worked there in former times, and, according to Diodorus Siculus, as far back as the time of the Phœnicians, after whom the Romans undertook to work them; and Pliny informs us, that thoſe nations derived great profit from them. Aſturia was the province which furniſhed moſt of this metal. After the diſcovery of America theſe mines were entirely given up and loſt. The Tagus and ſome other rivers of Spain are likewiſe auriferous.

France has no gold mine that is worthy to be worked; the firſt diſcovery of gold in that country was made in 1781, at la Gardette, in the valley of Oyſans, in the preſent department of the Iſere: the mine was worked for ſix years, but the produce in gold and accompanying minerals was too ſmall to compenſate for the expence of obtaining them, and, indeed, the loſs amounted to upwards of 21,000 livres. It occurs there, with rock cryſtals and iron pyrites, in gneiſs. The ſand of ſeveral rivers of France is auriferous, ſuch as that of the Arrieze near Mirepoix, the Gardon and Ceze in the Cévennes, the Rhone in the Pays de Gex, the Rhine between Straſburg and Philipſburg, the Salat in the neighbourhood of St Giron, in the Pyrenees, the Garonne near Toulouſe, and the Hérault at Montpellier. Alſo moſt of the black ſand and of the bog-iron found in the neighbourhood of Paris is ſaid to contain a ſmall quantity of gold.

In Piedmont veins of auriferous pyrites and quartz are found near Macugnaga, at the foot of Monte Roſa: which mountain conſiſts of veined granite in horizontal beds. The veins of pyrites and quartz have upon the whole a perpendicular direction, but in ſome parts they croſs each other, and where this takes place, *gruppi*, or neſts, are found which contain the greateſt proportion of gold. The proprietor of theſe mines extracted out of ſuch neſts, in no more than twenty-two days, 189 marcs of pure gold, although a hundred weight of the ore yields no more than from 10 to 12 grains of that metal. Formerly upwards of a thouſand workmen were employed in theſe gold-mines; and the proprietors ſtill poſſeſs 86 mills, by which from 10 to 12 pounds (of 12 ounces) of mercury inpregnated with gold are produced per day. Twelve pounds of mercury contain two marcs of gold. There are likewiſe ſeveral auriferous rivers on the S. ſide of the Apennine Alps, between mount Roſa and the valley of Aoſta, ſuch as the Avanſon, which runs from the valley of Challant into the Doire, and where ſome gold-mines were alſo worked by the Romans; the Orco, &c.

Sweden has a gold mine at Edelfors in Smoland: the gangue, a browniſh quartz, is ſaid to be in a kind of hornblende ſlate, which alſo contains the metal diſſeminated.

Gold has alſo been found in Great Britain: in Cornwall; at Lead-hills, in Scotland, diſſeminated in quartz; at Wicklow, in Ireland, under the ſoil, and in a ſtream which runs over rocks of clay-ſlate with veins of quartz. It belongs to the deep yellow variety.

Aſia.—The gold-ores of Siberia are partly of the light coloured, but principally of the deep coloured variety: that of Berezof, which occurs in pyrites, or rather brown iron ſtone, and iron ſhot quartz, and in the rock which ſerves as gangue to the red lead ore, belongs to the latter. Patrin mentions a ſpecimen of gold in ſpangles on hornſilver, found in one of the ſilver mines of Schlangenberg.

The geognoſtic relation of the gold found in ſeveral parts of India, in Japan, the Philippine and Maldive iſlands, Sumatra, Borneo, &c. is not known; all the ſpecimens from India, that have come under our inſpection, were in the form of ſmall rounded and amorphous particles in quartz, and belonged to the deep yellow variety.

Africa.—Of the occurrence of gold in this part of the world we know ſo much, that the greateſt part, at leaſt of that which comes to Europe, is deep yellow and in grains. African travellers have made us acquainted with a few of its localities, but not with any particulars relating to its geognoſtic habitudes. Though the commerce of gold-powder extends almoſt over the whole of Africa, yet, according to Heeren, there is none to be found in its northern parts. Among the principal African gold mines are thoſe of Kordoſan, between Darfur and Abyſſinia, mentioned by Browne. The ancients, ſays Brongniart, appear to have been acquainted with theſe mines: they conſidered Ethiophia as a country rich in gold; and we find in Herodotus, that the king of that country exhibited to the ambaſſadors of Cambyſes all the priſoners of war fettered with chains of gold.

A ſecond moſt conſiderable diſtrict for gathering gold-powder appears to be ſouthward of the great deſart of Zahara, in the weſt of Africa, at the foot of thoſe lofty ridges of mountains on which originate, among many ſmaller rivers, the Senegal, the Gambier, and Niger. The country of Bambouk, at the N.E. of theſe mountains, is, according to Golberry, that which furniſhes the greateſt quantity of gold which is ſold on the weſt coaſt of Africa, from the mouth of the Senegal to the Cape Palmas. This gold is found in ſpangles and ſmall lumps, principally near the ſurface of the earth, in the beds of rivulets, and always in a ferruginous ſoil. In ſome parts of the country the negroes ſink ſomething like ſhafts, but without giving any ſupport to the ſides of the pit; nor are they wont to follow up the vein, if any ſhould appear, or to make galleries. The metal is obtained by repeated waſhing of the earth that includes it. The ſame country furniſhes likewiſe the greateſt part of the gold carried to Morocco, Fez, and Algiers, by the caravans which, from Tombuctoo, travel through the great deſart of Zahara. The gold which is brought to Cairo and Alexandria from Senaar comes likewiſe from theſe. See Parke's travels, where alſo an intereſting account is to be found of the gold in Manding, and of the proceſs by which the negroes obtain it.

The third principal diſtrict of Africa, for collecting gold, is on the S.W. coaſt between 15° and 22° S. lat. oppoſite Madagaſcar. This gold comes principally from the country of Sofala. According to the relation of ſome travellers in this part of the world, the gold is found there not only in powder, but likewiſe in veins. Some are of opinion that the country of Ophir, from whence Solomon obtained gold, was ſituated on this coaſt.

America.—The gold of this part of the world, as far as we are acquainted with it, is ſo equally the production of the ſand of rivers and of alluvial land; but it is alſo, though rarely, found in veins. South America, particularly Braſil, Choco, and Chili, are the countries that yield moſt; but ſome is alſo found in North America, particularly in Mexico, where it occurs along with ſilver-ores. The annual produce of theſe Mexican mines is valued at from 12 to 1500 kilograms. All the rivers of the Caraccas, 10° north lat. are auriferous.

The gold of Chili, according to Frezier, is lodged in the alluvial formation.

The Peruvian gold occurs in ferruginous quartz; that of Choco, the richeſt province in gold in South America, is found as grains in alluvial country, and in rocks belonging to the neweſt fletz-trap formation. Almoſt all we know reſpecting the geognoſtic ſituation of the gold of Spaniſh America, we owe to M. de Humboldt.

Braſil furniſhes gold in abundance, and it is from thence that the greateſt part actually ſeen in commerce is brought to Europe. There are, however, properly ſpeaking, no gold-mines in that country; the gold is not found there in veins, but diſſeminated in ſand and other alluvial depoſitions, out of which it is obtained in the uſual manner.

The gold that has been furniſhed by Braſil within 120 years, may be valued (according to Correa) at 2,400,000,000 of French livres; and, according to other authors, the amount is calculated to be 24,000,000 per annum. Brongniart. See ORES.

Obſervations.—1. It would appear that moſt writers who adopt Werner's diſtinction between gold-yellow and braſs-yellow gold, have miſtakenly deſcribed the one ſub-ſpecies for the other, and ſome even ſpeak of "grey-yellow gold from Tranſylvania." The ſub-diviſion alluded to may be deemed inadmiſſible; but if it be at all adopted, by far the greater part of the native gold of Tranſylvania and Hungary, and conſequently almoſt all cryſtallized gold, muſt neceſſarily be referred to the light-coloured, and that found in the ſand of rivers to the deep-coloured ſub-ſpecies; and this not on account of their colour only, uſually indicative of differences in the chemical compoſition of metals, but principally on account of the geognoſtic relations under which they reſpectively occur, and on which great ſtreſs appears to be laid by Werner.

2. Iron pyrites, containing not unfrequently a conſiderable portion of gold, in moſt caſes inviſibly diſperſed and diſguiſed, has by ſome been conſidered as a ſpecies of gold ore; a diſtinction to which (though ſuch auriferous pyrites are often ſubjected to metallurgical treatment for extracting that metal, as will be ſeen hereafter) it cannot be conſidered as entitled. See PYRITES, *Auriferous*.

The brown cubic cryſtals from Bereſof, in Siberia, which contain grains of gold, are conſidered by ſome as decompoſed, by others as hepatic pyrites, and by ſome as brown iron ſtone in ſuppoſititious cryſtals. Whatever they may be, they are certainly not what Werner means by hepatic pyrites.

3. The native gold of Tranſylvania is often accompanied, and ſometimes incruſted, by particles of a pale yellow earthy ſubſtance, which was conſidered by Hacquet as an oxyd of gold. Muller and others have deſcribed it as iron-ochre, from which, however, it appears to differ both in colour and conſiſtence. It is almoſt always to be met with in the ſpecimens of native gold from Vereſhpatak, but ſometimes in ſuch fine particles as to appear merely as a tarniſh on the metal. It is to this duſt probably that the gold ore, called Spaniſh ſnuff, owes its mat, yellowiſh-brown colour. It deſerves further examination.

4. The grey metallic ſubſtance occurring as acicular indeterminate cryſtals, along with the gold of Siberia, in quartz, and which has been deſcribed as tellurium, as grey copper ore, &c. appears to be native biſmuth.

For the *chemical characters* of gold, and the *uſes* to which it is applied, ſee the ſequel of this article.

Extraction of Gold.—This metal is obtained ſeparate from foreign ſubſtances, with which it is mixed by amalgamation with quickſilver. After it has been freed, by pounding and waſhing, from the ſtony matter, it is triturated with about ten times its weight of mercury. The more fluid part of the amalgam is forced through leather, while that which is more conſiſtent, and which contains the chief part of the gold, remains. This is ſubjected to diſtillation, the quickſilver is ſeparated and evaporated, and the gold remains in a ſtate of fuſion. When this metal is found in other ores, they are firſt roaſted, to diſperſe the volatile principles, and to oxidize the other metals. The gold, which is but little ſubject to oxydation, is extracted by amalgamation, by cupellation, or other methods adapted to each ore, according to its properties or conſtituent parts. The metal obtained in theſe ways is always more or leſs alloyed, particularly with ſilver and copper. The firſt ſtep in its purification is the proceſs of *Cupellation*, to which article in our Cyclopædia the reader is referred for accurate information on this part of the ſubject.

The gold, after it has been ſubmitted to this proceſs, is often alloyed with ſilver, which, being nearly as difficult of oxydation, is not removed by the action of lead, and hence the neceſſity of the operations denominated *Parting* and *Quartation*, which may be explained in a few words.

In *Parting*, the metal is rolled out very thin, and cut into ſmall pieces, which are digeſted in diluted nitric acid moderately hot. The acid has an action upon, and diſſolves the ſilver, leaving the gold undiſſolved in a porous maſs. When, however, the proportion of ſilver is very ſmall in compariſon of the gold, the latter ſometimes protects the former from the action of the acid; in ſuch caſes the previous ſtep of *Quartation* is employed, which is ſo named on account of the proportion of materials employed, *viz.* three parts of ſilver, with one of gold, and then ſubjecting the alloy, rolled out, to the operation of the acid. Sometimes they are melted together, and ſulphur thrown in, the ſulphur combines with the ſilver, and the gold falls to the bottom. It is obſerved by Lagrange, that rolling and annealing are operations very neceſſary to the ſucceſs of the parting proceſs, and which require ſome precautions. 1ſt. The plate muſt not be too thin, leſt it ſhould break in conſequence of the motion communicated to it by the action of the acid; if it is too thick the acid could not penetrate to its centre. 2dly. The annealing of the plate, at the ſame time that it gives pliability, facilitates its being rolled without cracking; it alſo opens the pores of the metal, which the rolling may have preſſed together, and by theſe means favours the action of the acid.

The proceſs recommended by Bergman is this: firſt to diſſolve it in nitro-muriatic acid; the ſilver is depoſited ſpontaneouſly in the form of muriate of ſilver, which is inſoluble; the gold is precipitated in fine powder by the ſulphate of iron. Each of the above-mentioned proceſſes is performed in ſuch a manner as to lead to an eſtimate of the quantity of gold, and alſo of the different metals with which it is alloyed.

Gold, it is ſaid, by ſome able French chemiſts, as Le Sage and Rouelle, exiſts in the vegetable kingdom, it having, in experiments inſtituted for the purpoſe, been extracted from the aſhes of certain plants; the quantity, however, being, of courſe, too trifling to be ſought after for practical purpoſes, it is ſufficient merely to mention the fact in this place.

Gold, *Chemical Properties of.*—Gold melts at the temperature of 32° of the ſcale of Wedgewood; and what is very remarkable is, that it is more difficult of fuſion in the ſtate of filings and grains, than in larger maſſes; and that the ſmall fragments, even after they are fuſed, remain in ſeparate globules: and in order to make them run into one maſs, a little nitre or borax is thrown into the crucible. Gold, which has only been ſubjected to a degree of heat barely neceſſary for its fuſion, is brittle after cooling. To preſerve its ductility, which, as will be ſeen farther on, is one of the more important mechanical properties of gold, the temperature muſt be raiſed much higher. It is brittle alſo when it is too ſuddenly cooled after fuſion. By an increaſe of temperature while the gold is in fuſion, it becomes convex on the ſurface, and when it cools, it ſinks, circumſtances which are aſcribed to the expanſion and contraction of the metal. When it is gradually and ſlowly cooled, it cryſtallizes in the form of quadrangular pyramids, or regular octahedrons. If the heat be continued while it is in perfect fuſion, it ſeems to undergo a kind of ebullition. This circumſtance was noticed by Homberg and Macquer, as well in the application of the burning-glaſs, as when a ſmall globule of the metal was acted on by the blow-pipe. Macquer aſſerts that it roſe in vapour to the height of five or ſix inches, and attached itſelf to the ſurface of a ſilver plate, which it completely gilded.

The ſtrongeſt heat of a furnace, which has been applied to gold in fuſion, has been found incapable of producing the ſmalleſt change or the leaſt tendency to oxydation; but, by the action of a very powerful burning-glaſs invented by Tſchirnhauſen, and which has been deſcribed under the article Burning-glass, Homberg found that gold, placed in its focus, not only roſe in vapour, but that it was covered with a violet-coloured vitreous oxyd. The experiment was frequently repeated, ſo as to aſcertain the fact moſt completely. The ſame thing has been done by means of the electric diſcharge, by which gold-leaf, placed between two cards, has been converted into a violet-coloured powder. Theſe inſtances of real oxydation were, at firſt, regarded, by ſome who witneſſed the experiments, as merely minute mechanical diviſions of the metal, but this apparent objection has been removed by the experiments of Van Marum on the combuſtibility of gold by means of the large electrical machine at Haerlem. A ſtrong electrical ſhock was paſſed through a golden wire ſuſpended in the air. It kindled, burned with a perceptible green flame, and was reduced to fine powder, which was diſſipated in the air. A ſimilar oxydation has been obſerved to take place on the gilding in the inſide of houſes, or on the furniture which has been ſtruck with lightning. The purple oxyd of gold, thus obtained, contains five or ſix *per cent.* of oxygen. By precipitation from ſome of its ſaline combinations, a yellow oxyd has been obtained, in which the proportion of oxygen amounts to ten *per cent.* The oxyd in both inſtances may be decompoſed, and the oxygen completely expelled, by an elevation of temperature not much ſuperior to that of ignition.

The attraction of gold to oxygen is ſo weak, that it is ſcarcely affected by the greater number of acids. It was formerly ſuppoſed to be perfectly inſoluble in the nitrous and nitric acids, which in general part with oxygen with ſo much facility, and when gold leaf is put into the acid cold, it ſeems to ſuffer no change, but when nitric or nitrous acid is boiled on gold, it is capable of diſſolving a ſmall portion of it. The quantity diſſolved is, however, ſo inconſiderable, and depends on ſo many conditions, which it is needleſs to enumerate, that the accuracy of the proceſſes of aſſaying can ſcarcely be affected by it.

When gold is diſſolved in the nitro-muriatic acid, or in a mixture of equal parts of nitric and muriatic acids, an efferveſcence takes place, and the ſolution becomes of a yellow colour. In this proceſs the nitric acid is decompoſed, its oxygen combines with the gold, and the oxyd, as it is formed, is diſſolved in the muriatic acid. By adding lime-water a precipitate is formed, which is the yellow oxyd of gold, conſiſting of from eight to ten parts of oxygen in the hundred. There is no action between gold and azote, hydrogen, carbon, or ſulphur: but the oxyds of gold are readily decompoſed by hydrogen, as will be ſoon ſeen.

Phoſphorus combines with gold by heating together in a crucible a mixture of one part of gold in filings, with two parts of phoſphoric glaſs, and an eighth part of charcoal. Great part of the phoſphorus is ſeparated from the acid, and driven off, but there remains a ſmall quantity united with the gold, forming a phoſphuret of gold. It may be done alſo by adding phoſphorus to gold in a red heat in a crucible. It is, in this ſtate, pale coloured, granulated, brittle, and a little more fuſible. The proportion of phoſphorus is not more than one part in twenty-four; and the ſubſtance may be decompoſed by being kept in fuſion; the phoſphorus is driven off in the ſtate of vapour, and inflamed. Bergman has arranged the affinities of gold and its oxyds in the following order:

Gold.	*Oxyds of Gold.*
Mercury,	Muriatic-acid,
Copper,	Nitric,
Silver,	Sulphuric,
Lead,	Arſenic,
Biſmuth,	Fluoric,
Tin,	Tartaric,
Antimony,	Phoſphoric,
Iron,	Pruſſic.
Platina,	
Zinc,	
Nickel,	
Arſenic,	
Cobalt,	
Mangeneſe.	

Salts of Gold.—Theſe are the nitrate and muriate.

1. *Nitrate of Gold.* When concentrated nitric acid is ſeveral times ſucceſſively poured upon gold, boiled and diſtilled to dryneſs, the gold is diſſolved, and the ſolution aſſumes a yellowiſh colour. This ſolution is more readily effected in proportion to the quantity of gas or nitrous gas which the acid contains. Gold-leaf, according to Fourcroy, is diſſolved in nitric acid, impregnated with nitrous oxyd, and he ſuppoſes that it is owing to the nitrous oxyd that the gold is oxydated, this oxyd being ſo much more eaſily decompoſed than the nitric acid. The acid which, at firſt, is deprived of its colour by the oxydation of the gold, as this oxyd is diſſolved, aſſumes an orange-yellow colour, holding in ſolution the nitrate of gold with an exceſs of acid. The nitrate cannot be obtained in cryſtals, and it is decompoſed by heat or by being expoſed to the light of the ſun; it is alſo decompoſed by the alkalies, or by introducing a plate of tin or ſilver into the ſolution, and the purple oxyd is precipitated in the form of powder; and likewiſe by muriatic acid, which at the inſtant of combination converts the orange-colour to a pure yellow.

2. *Muriate of Gold.*—Muriatic acid of itſelf has no action on gold, or on its purple oxyd, but gold is immediately oxydated and then diſſolved in oxymuriatic acid: or if nitric acid be added to the muriatic in certain proportions, the ſolution of gold in the mixture is readily effected: hence the nitro-muriatic acid was diſtinguiſhed by the name of "aqua regia," becauſe it diſſolved gold, which was regarded by the alchemiſts as the king of metals. The nature of the chemical action is thus explained. Gold is oxydated with great difficulty, but it is effected by oxymuriatic acid, which readily parts with its oxygen, or by the addition of the nitrous to the muriatic, the former of which is decompoſed, giving out its oxygen to the gold, which being now oxydated is diſſolved in the muriatic acid, forming with it a muriate of gold. This ſolution of the muriate of gold is of a deep yellow colour, extremely acrid and cauſtic; has an aſtringent metallic taſte, and ſtains the ſkin of a deep purple colour, which becomes darker by expoſure to the air and light. It produces a ſimilar effect on all vegetable and animal matters, and on marble and ſiliceous ſtones. By evaporating the ſolution to one half, nitric acid is diſengaged, and cryſtals are obtained. Theſe aſſume a red colour by the action of ſtrong light. They attract moiſture from the air, and ſpontaneouſly become liquid. When oxymuriatic acid is uſed, the oxygen of this acid being retained even by a weaker affinity than the nitric acid, the gold attracts it, and combines with the muriatic acid. In this caſe the ſolution is ſlow, and but a very ſmall quantity of gold can be diſſolved, partly from the oxymuriatic acid not being in a very concentrated ſtate, and partly, it is ſuppoſed, from the quantity of oxygen preſent not being ſuch as to form a ſufficient quantity of oxyd to ſaturate the acid. It ought, however, to be obſerved, that if the late diſcoveries of profeſſor Davy be eſtabliſhed, which make the oxy-muriatic acid a ſimple ſubſtance, and even poſſeſſing no oxygen whatever, then a new theory muſt be introduced to account for the facts above-ſtated. In oxy-muriatic gas, gold-leaf is inſtantly fuſed with inflammation, and diſſolved.

Gold cannot be diſſolved by the other acids when in its metallic ſtate, but its oxyds may be combined with them, and a number of the ſalts of gold be formed. The ſulphate and nitrate alſo, as we have ſeen, do not cryſtallize: the phoſphate of gold may be fuſed, and in this ſtate it forms a fine red glaſs. We ſhall now briefly notice ſome of the properties of the muriate of gold. In connection with this ſubject, we muſt not omit the experiments of Mrs. Fulhame, which ſhe announced in an "Eſſay on Combuſtion," with a view to a new art of dyeing and painting, &c. in the year 1794, and which were, at that period, expected to lead to ſome important practical reſults.

The muriate of gold is very ſoluble in water, and is decompoſed in hydrogen gas. If a piece of ſilk be moiſtened with a ſolution of muriate of gold, the ſalt is decompoſed, and the gold, reduced to the metallic ſtate, attaches itſelf to the ſilk. It is decompoſed alſo by phoſphorus. If a ſtick of phoſphorus be introduced into a ſaturated ſolution of muriate of gold, the ſalt is decompoſed, and the gold, being reduced to the metallic ſtate, forms a cylindrical covering to the phoſphorus, which may be ſeparated by diſſolving the latter in hot water. A ſimilar effect is produced by burning ſulphur, by ſulphurated and phoſphorated hydrogen gaſes, and by ſulphurous acid. If a ſolution of muriate of gold be cautiouſly added to ſulphurous acid, a fine pellicle of gold appears on the ſurface, which is inſtantly precipitated in the form of ſmall grains. Theſe, and many other experiments equally curious and intereſting, were firſt deſcribed by the lady above-mentioned, and the rationale of the ſubject is thus explained. All the ſubſtances which have been enumerated have a ſtronger affinity for oxygen than gold, ſo that the oxyd of gold, in combination with the acid, is decompoſed; the oxygen combining with the hydrogen, and forming water, or with the phoſphorus or ſulphur, and forming ſulphuric or phoſphoric acid.

The muriate of gold is ſoluble in ether, and forms with it a ſolution of a golden yellow colour, which floats on the top of the fluid. By the addition of ether to a ſolution of gold, and agitating the mixture, as ſoon as it is left at reſt, the two liquids ſeparate, the ether riſes to the top, and aſſumes a yellow colour, while the nitro-muriatic acid remains below and becomes white. By a proceſs of this kind a tincture of gold was prepared, called "potable gold." The ſolution of gold in ether is not permanent: it is quickly reduced to the metallic ſtate, and is ſometimes found cryſtallized on the ſurface. The etherial ſolution is uſed by Mr. Stodart for defending lancets, and other ſurgical inſtruments, from injury by a moiſt atmoſphere.

The muriate of gold is decompoſed by all the alkalies and earths, and is reduced to the ſtate of yellow oxyd.

Moſt of the metals decompoſe the muriate of gold: copper, iron, zinc throw down the gold in its metallic ſtate: other metals, as ſilver or lead, in the ſtate of purple oxyd. The precipitate obtained by means of tin is valued for the beauty of the colour which it gives to glaſs or enamel. This preparation is known to artiſts by the name of the "Purple powder of Caſſius," and it may be obtained by various proceſſes. That which is commonly reſorted to, is to diſſolve pure gold in a nitro-muriatic acid, which is compoſed of three parts of nitric and one of muriatic acid. A ſolution of tin is to be prepared by diſſolving the metal, in ſmall portions at a time, in an acid containing two parts of nitric and one of muriatic acid, previouſly diluted with an equal weight of water. This ſolution, after it is ſaturated, is largely diluted, perhaps with a hundred parts of diſtilled water: to this the ſolution of gold equal in quantity to half the quantity of ſolution of tin, is added, and the precipitate is obtained after it is allowed to ſubſide, which is to be waſhed and dried. This is the only known preparation capable of giving a red colour to glaſs; and if the experiment be performed with accuracy and judgment, the glaſs ſo treated ſerves as a capital imitation of the ruby. The proceſs is, however, attended with conſiderable difficulty, owing to the colour of the precipitate being various, from circumſtances not eaſily diſcovered. According to Pelletier, it is a compound of oxyds of tin and gold; and its formation is owing to the ſtrong attraction of the tin for the oxygen, with which it is diſpoſed to combine in large quantities. When the ſolutions, above deſcribed, are mixed, the oxyd of tin, which is nearly at the minimum of oxydizement, attracts part of the oxygen of the oxyd of gold: the two oxyds thus brought to ſtates of oxydizement, different from thoſe in which they exiſted in the ſeparate ſolutions, and probably likewiſe exerting mutual affinities, are no longer ſoluble, and are precipitated in combination. Muriate of gold is decompoſed by ſome other metallic ſalts, in conſequence of ſimilar actions; the oxygen of the oxyd of gold being attracted by the oxyd of the other metal, which hence paſſes to a higher ſtate of oxydizement. Thoſe which have a ſtrong tendency to exiſt in ſuch a ſtate, are capable even of completely de-oxydizing the oxyd of gold. Example.—If a ſolution of the green ſulphate of iron be added to the ſolution of muriate of gold, the gold is precipitated in very minute particles in the metallic ſtate, while the iron paſſes to the ſtate of a red ſulphate. A ſolution of muriate of gold, when concentrated by evaporation, yields beautiful yellow cryſtals, not unlike topazes.

Gold, as we have ſeen, does not combine with ſulphur by fuſion, and on this is founded a method of freeing it from ſilver or other metals, the alloy being fuſed with ſulphur, the ſilver, &c. unite with the ſulphur, leaving the gold ſeparate. But gold and ſulphur may be united by the medium of an alkali. Example.—Let a ſulphuret of potaſh be fuſed with one-eighth of its weight of gold-leaf, and the combination is even ſoluble in water, the ſolution being of a green colour.

Alloys of Gold.—Gold forms alloys with the greater number of the metals, which produce on the metal ſo alloyed a very particular change in its properties. An extenſive and accurate ſeries of experiments on theſe alloys was made by Mr. Hatchet, with the view of determining ſome important and intereſting facts relating to the uſe of gold as a coin. Of theſe we ſhall give a brief abſtract, referring our readers for a more particular account to the Tranſactions of the Royal Society for the year 1803.

The chief enquiry of Mr. Hatchet, as connected with the alloys of gold, was, whether ſoft and ductile gold, or gold made as hard as is compatible with the proceſs of coining, ſuffers moſt by wear. His experiments were intended to examine the effects which various metals produce upon gold, when combined with it in given proportions, beginning with $\frac{1}{12}$th, which is the ſtandard proportion of alloy, and gradually decreaſing to $\frac{1}{1920}$ part of maſs. The reſults drawn from the trials were, that fine gold, alloyed with ſilver, with copper, and with tin, did not ſuffer any loſs during the experiment. The gold alloyed with lead only loſt three grains, chiefly by vitrification; with iron it loſt 12 grains, which formed ſcoria; with biſmuth it loſt 12 grains, chiefly by vitrification; with zinc it loſt a pennyweight by volatilization; and with arſenic, it not only loſt the whole quantity of alloy, but alſo two grains of the gold which were carried off in conſequence of the rapid volatilization of the arſenic. Hence it was inferred that only two metals are proper for the alloy of gold coin, namely, ſilver and copper; as all the others either conſiderably alter the colour, or diminiſh the ductility of gold. In reſpect to the latter quality, the different alloys employed in this ſeries of experiments appear to affect gold nearly in the following decreaſing order: 1. Biſmuth. 2. Lead. 3. Antimony. 4. Arſenic. 5. Zinc. 6. Cobalt. 7. Manganeſe. 8. Nickel. 9. Tin. 10. Iron. 11. Platina. 12. Copper, and, 13. Silver. The three firſt have nearly the ſame effect on gold, and biſmuth is found to render gold brittle when the proportion of that metal is to gold only as 1 to 1920; even the vapour ariſing from biſmuth, lead, and antimony in fuſion, produces theſe changes.

The alloy with platina is of a yellowiſh white colour, very ductile, and of a conſiderable ſpecific gravity. The alloy with ſilver in the ſtandard proportion, or 1 to 12, approaches, as we have ſeen above, the neareſt to the ductility of fine gold of any alloy, and its ſpecific gravity differs but little from the mean ſpecific gravity of the two metals. When the ſilver amounts to $\frac{1}{5}$th, the colour of the alloy approaches to green, and forms the green gold of the goldſmiths. In combination with copper, gold has its colour rather heightened than impaired; its hardneſs is increaſed and its ductility very little leſſened, when the ſtandard proportion of 1 part in 12 is not exceeded. This alloy of 22 carats fine is generally uſed, when gold is fabricated into plate or ornaments, and likewiſe forms the gold coin of the country. With quickſilver, gold unites with great facility, making with it an amalgam which will be deſcribed hereafter. The alloy with iron is much harder than gold, very ductile and malleable; but the colour is debaſed to a dulliſh grey, inclining to white. Tin was formerly regarded as the metal which rendered the alloy with gold the moſt brittle of all the alloys, but the experiments of Mr. Bingley and Mr. Hatchet have ſhewn that this notion is to a certain extent erroneous, and that the effects produced by the mixture of tin with gold, ought probably to be aſcribed to other metals, with which the tin was contaminated, ſuch as biſmuth, antimony, lead, and zinc. The alloy, conſiſting of equal parts of zinc and gold, is very hard and ſuſceptible of a fine poliſh, and not being ſubject to much alteration from the air, it is recommended for the fabrication of the mirrors of teleſcopes. The alloy of gold with ſilver, in which there is only $\frac{1}{70}$th part of ſilver, changes the colour of the gold very ſenſibly; and the alloy is employed for ſoldering gold, being more fuſible than this metal.

Gold, *Phyſical properties of.* *Gold*, *aurum*, a yellow metal, heavy, pure, ductile, malleable, and ſhining; and on thoſe accounts, the moſt valuable of all metals. In fuſibility it ranks between ſilver and copper; it is not oxydable by fuſion in atmoſpheric air; nor is it acted upon by any of the acids, except the oxymuriatic and nitro-muriatic.

The yellow colour of gold is rendered paler by fuſion with borax; but this may be prevented or corrected by fuſion with nitre, or ſal ammoniac. The colour of gold is heightened by an alloy of copper, and this property of copper has given riſe to ſundry proceſſes for exalting the colour of this noble metal. Other metals render it paler. The alchemiſts call gold, *ſol*, the ſun; to denote its pre-eminence over the other metals, which are called by the names of the planets. Its ſymbol, or character, is ☉; which, in their hieroglyphical way of writing, denotes perfection, ſimplicity, ſolidity, &c.

The weight of gold is to that of water, according to ſome ſtatements, as 19.637 to 1000. Fine gold, immerſed in water, weighs nearly one nineteenth part leſs than in air, and conſequently it is upwards of nineteen times heavier than its own volume of water. However, the ſpecific gravity of gold, or its comparative weight with an equal volume of water, has been variouſly aſſigned: ſome have made it 19.637, others 19.640, and in the Swediſh Tranſactions it is made no leſs than 20.000; that of water being 1000. Others again have made it as low as 18.75. But from the experiments of Mr. Ellicot, it does not appear to have exceeded 19.207; and from thoſe of Dr. Lewis, on the pureſt gold, well hammered, its gravity is ſtated between 19.300 and 19.400. In all experiments of this kind, the reſult ſhould be ſpecified with an account of the ſenſibility of the balance, and the quality and warmth of the water. An increaſe of heat rarefying water more than it does gold, the gold muſt turn out proportionably heavier than an equal volume of the expanded fluid; and this difference is more conſiderable than it has generally been ſuppoſed. From freezing to boiling water, or by an augmentation of heat equivalent to 180° of Fahrenheit's thermometer, Dr. Lewis found that a rod of gold was lengthened about one part in 700, and conſequently its volume increaſed about one part in 233, while the volume of water is increaſed one twenty-ſixth or more; hence it appears, that by an augmentation of 40° of the thermometer, or from a little above freezing to the ſummer heat, the volume of gold, if its expanſion be uniform, is increaſed one part in 1048, and that of water one in 117; and the gravity of gold, weighed in the water ſo warmed and expanded, ſhould be greater than when the gold and water are 40° colder, in the proportion of about 19.265 to 19.400: and this calculation gives a difference, in the gravity, of 0.034 for every 10° of the thermometer; but ſome trials ſeemed to make it greater. It has been imagined, that the comparative gravity of gold to braſs weights, which are more than double in volume to an equal weight of gold, muſt be ſo far influenced by the variable gravity of the atmoſphere, that there muſt be an advantage in buying gold by weight when the air is lighteſt. But Dr. Lewis obſerves, that this difference appears too inconſiderable to be regarded in a commercial view. For the loſs of weight of the two metals in the air being as much leſs than their loſs in water, as air is lighter than water; and air, if we admit the accuracy of the concluſion deduced from an experiment of Mr. Hawkſbee, being in its lighteſt ſtate about a 937th, and in its heavieſt ſtate about an 848th part of the weight of water; it will be found, on calculation, that the gold preponderates above the braſs, in the heavieſt more than in the lighteſt air, only by one part in 145.000, or one grain in about 302 ounces; which is a difference too minute to be ſenſible in the niceſt balance. If the mean gravity of gold be reckoned 19.300, as a cubic inch of water weighs about 254 grains, a cubic inch of gold will conſequently weigh about 4902 grains, or 10 ounces, 102 grains. The pound weight, or twelve ounces Troy, of gold, is divided into twenty-four carats. Dr. Lewis ſtates the ſpecific gravity of fine gold at 53° Fahrenheit, to be 19.376. According to Briſſon the ſpecific gravity of fine gold in ingot is 19.258, and when hammered 19.361. The ſpecific gravity of gold made ſtandard by Britiſh copper, was found by Mr. Hatchett (ſee Phil. Tranſ. for 1803) to be 17.281, when caſt in an iron mould; but when the ſame was caſt in ſand, it was only 16.994. (See *Specific* Gravity.) The ſoftneſs of gold, for it is nearly as ſoft as tin, and its toughneſs, adapt it for receiving the impreſſions of dies, and of courſe to be reduced to the ſtate of coin, and for various other purpoſes in the arts. It is but ſlightly elaſtic and ſonorous. With regard to tenacity, it is inferior to iron, copper, platina, and ſilver, and therefore the aſſertions of former chemiſts and philoſophers have been contradicted by later experiments, for gold has been uſually repreſented as the moſt tenacious as well as the moſt ductile of all metals. Its malleability and ductility are ſufficiently evinced by the Gold-*leaf* and Gold-*wire*, which ſee. See alſo Ductility.

The value of gold to that of ſilver, was anciently only as twelve to one. Indeed, this proportion varies as gold is more or leſs plentiful: for Suetonius relates, that Cæſar brought ſuch a quantity of gold from Italy, that the pound of gold was only worth ſeven pounds and a half of ſilver. In our coinage, the value of fine gold to fine ſilver is nearly as 15$\frac{1}{5}$ to 1. (See Coin and Standard.) Sir Iſaac Newton obſerves, in a repreſentation to the lords of the treaſury in the year 1717, that in the mints of Spain and Portugal the value of gold is ſixteen times that of ſilver; but that in thoſe countries, payments in ſilver bearing generally a premium of ſix per cent. the proportion may be conſidered as fixed by commerce at $15\frac{1}{15}$ to 1; that in the other parts of Europe, the value of gold is at moſt fifteen, and in China and Japan but nine or ten times that of ſilver; ſo that gold is rated higher in England than in any other part of Europe, and higher in Europe than in the Eaſtern countries. Hence, in great meaſure, ariſe the profits of exchanging gold for ſilver in one place, and re-exchanging them in another; and hence the greater diſparity between the relative quantities of gold and ſilver in one commercial nation than in another; this metal being brought in moſt abundance which is rated higheſt in proportion to the other, and that which is rated loweſt being drained away. There are various ways of determining the fineneſs of gold; or the proportion of alloy which it contains. Thoſe who are uſed to this buſineſs can judge nearly the proportion of alloy from the colour of any given maſs, provided that the ſpecies of alloy be known. For the method of doing this, ſee Touch-*needles*. The great exceſs of the weight of gold, above that of the metals uſed for its alloy, affords another method of determining the quantity of alloy in any given maſs, where the ſpecies of alloy is known. Thus fine gold loſes in water one grain in every 19.3 nearly; and fine ſilver loſes one grain in about eleven; from whence it is eaſy to find the loſs of any number of grains of each, and conſequently of any aſſignable mixture of the two metals. Thus, fifty grains of gold will loſe above $2\frac{1}{2}$, and fifty grains of ſilver ſomewhat more than $4\frac{1}{2}$; ſo that a mixture of equal parts of the two will loſe above ſeven in a hundred, or one in fourteen. A mixture of gold with half its weight of ſilver will loſe one part in 15.4; with a third of ſilver, one in 16.2; with a fourth, one in 1.67; and with an eleventh of ſilver, which is the ſtandard proportion of alloy, one in 18.1. On this principle, the ſpecific gravity or proportional loſs in water, of gold alloyed with different quantities of ſilver, copper, and mixtures of both, may be computed and formed into tables for uſe. The accuracy of this method, it ſhould be obſerved, depends on the ſuppoſition that each of the two metals, that are melted together, retains its own proper gravity, which is the caſe in mixtures of gold and ſilver; but gold and copper, melted together, are ſpecifically lighter than if they were weighed ſeparately; or the ſpecific gravity of the alloy is leſs than that of the mean of its ingredients; the caſe is the ſame with the alloys of nickel and gold, of lead and gold, of iron and gold; but the reverſe happens in mixtures of gold with zinc, biſmuth, and tin. It appears, therefore, that the hydroſtatic balance cannot diſcover, with certainty, the exact fineneſs of gold, unleſs when ſilver is the metal mixed with it.

There are various methods of ſeparating gold from gilt works: it may be ſeparated from the ſurface of ſilver, either by ſpreading over the gilt ſilver a paſte made of powdered ſal ammoniac moiſtened with aquafortis, and heating it till the matter ſmokes, and is nearly dry; throw it into water, and the gold will eaſily come off by rubbing it with a ſcratch bruſh: or, by putting the gilt ſilver into common aqua regia, nearly boiling, and turning the metal frequently, till it becomes all over black; then waſh it with water, and rub it with the ſcratch bruſh, which will diſengage the gold left by the aqua regia. See Gilding.

Gold may be ſeparated from gilt copper, by applying a ſolution of borax to the gilt parts with a pencil, and ſprinkling over the place thus moiſtened a little powdered ſulphur; when the piece is made red-hot and quenched in water, the gold may be wiped off with a bruſh.

Gold may be recovered from wood, gilt on a water ſize, by ſteeping it for a quarter of an hour in a quantity of very hot water, ſufficient to cover it; then ſcrub the wood in a little warm water, with ſhort ſtiff briſtle bruſhes of different ſizes: boil the whole mixture of water, ſize, gold, &c. to dryneſs; make the dry matter red-hot in a crucible to burn off the ſize, and grind the remainder with mercury. The gold will be more eaſily laid hold of by the mercury, by the addition of ſome clean ſand.

Gold, *Alchemical Hiſtory of*. See Philosopher's *Stone*, and Transmutation.

Gold, *Amalgam of*, is a preparation of gold much uſed by the gilders (ſee Gilding); and it is made by heating ſome pure quickſilver in a clean crucible, and adding to it, when it is nearly boiling, about a ſixth of its weight of fine gold in thin plates that are hot; after this mixture has been kept hot for a few minutes, it becomes an homogeneous ſubſtance; and when cold, it is put into a piece of ſoft leather, and which is gradually preſſed till the fluid part of the amalgam, conſiſting almoſt wholly of mercury, is forced through the pores of the leather; while the gold, combined with about twice its weight of mercury, will remain in the ſtate of a yellow ſilvery maſs, of the conſiſtence of ſoft butter; when this maſs has been bruiſed in a mortar, or ſhaken in a phial, with repeated portions of ſalt and water, till the water receives no foulneſs from it, it is fit for uſe, and may be preſerved for any time in a corked phial. For the purpoſes of gilding it is of great importance, that this amalgam ſhould be formed of pure materials, as any portion of lead or biſmuth would deteriorate the colour of the gold, and tarniſh it with black ſpecks. The mercury ſhould therefore be previouſly diſtilled from the red precipitate (nitrous red oxyd of mercury), either alone or mixed with a little charcoal powder. See Amalgam and Mercury.

Gold-*beating*, and Gold-*beater's ſkin*. See Gold-*leaf*.

Gold, *Burniſhed*, is that which is poliſhed with a ſteel inſtrument, called a burniſher, if it be wrought gold, or gilding on metal; or with a wolf's tooth, if it be gilding in water. See Gilding.

Gold *Chain*. See Chain.

Gold *Coin*, or *ſpecies of gold*. See Coin and Coinage.

Gold-*coloured Glazing*. See Glazing.

Gold-*coloured Metal* is produced by melting zinc with copper. According to the purity of the zinc and copper, the proportions in which they are mixed, and the intimacy of their union, the compound metal proves more or leſs malleable, and approaches more or leſs to the colour of gold. Some direct the zinc to be taken only in a fifth or ſixth part of the weight of the copper, and others in an equal weight or more. Dr. Lewis obſerves, from the reſult of many experiments, that both with the ſmalleſt and largeſt of theſe quantities of zinc, the metal proves more like gold than with the intermediate proportions.

The colour of theſe compounds is improved by a ſmall mixture of ſome other metallic bodies. Cramer recommends the addition of a ſmall quantity of pure tin to copper, melted with a fourth or ſixth part of zinc, which forms a compound metal, that acquires, on being well cleaned, and laid in the air for ſome days, a ſuperficial colour of fine gold. Geoffroy ſays that iron has the beſt effect: with the proportions of ten parts of zinc, eight of copper, and one of iron-filings, he produced a metal of a fine ſmooth grain, compact, hard, and bright, and of a beautiful gold colour. By making the copper firſt into braſs, and then melting it with a ſuitable quantity of zinc, a metal may be obtained of ſuperior quality to that produced either by melting the copper and zinc, or by impregnating the copper with zinc, by cementation and fuſion with calamine; which is a method ſometimes practiſed. A very ingenious artiſt, ſays Dr. Lewis, who now prepares a gold-coloured metal in great perfection, has a fine kind of braſs made on purpoſe for this uſe. The union of the copper and zinc in fuſion, ſucceeds beſt and with leaſt loſs of the zinc, according to Dr. Lewis, by uſing a mixture of black flux and borax, or a compoſition of twelve parts of green glaſs powdered, ſix parts of potaſh, two of borax, and one of powdered charcoal: when this flux is fuſed in the crucible, the copper and zinc are dropped into it; and when they appear perfectly melted, they are to be well ſtirred together with an iron rod, and expeditiouſly poured out. The ſame flux will ſerve for melting ſeveral freſh quantities of the metal. Dr. Hooke gives the following receipt for making a gold-coloured metal: eight parts of diſtilled verdigris, *i. e.* of verdigris purified by ſolution in diſtilled vinegar and cryſtallization, and four parts of Alexandrian tutty, with two of nitre, and one of borax, are directed to be mixed with oil to the conſiſtence of pap; then melted in a crucible, and poured into a flat mould firſt well warmed. A compoſition of this kind is called *aurum ſophiſticum*.

The following method is recommended by Homberg for giving a gold colour to copper, without the addition of zinc; make an amalgam of one part pure copper, and three parts quickſilver; boil this in river-water for two hours, then diſtil off the quickſilver in a retort, and cohobate it once; take out the copper and fuſe it, and it will be found of a beautiful gold colour, more ductile than common copper, and extremely well fitted for watch-work, gilding, and the finer machines and utenſils. The celebrated Mr. Pott affirms that a gold-coloured metal may be made from a mixture of copper and tin, and directs it to be compounded in the following manner: Take one half ounce of tin aſhes, and four half ounces of copper; melt them well together in a cloſe luted crucible, with a ſtrong fire; or take one half ounce of the pureſt tin cut in pieces, and ſixteen half ounces of pure copper beaten into thin plates; lay the tin between the copper-plates, lute the crucible cloſe, and melt with a ſtrong fire. See *Prince's* METAL and TOMBAC.

Silver is tarniſhed ſuperficially, by certain vapours, as that of putrified urine, to a colour ſo like that of gold, that ſeveral edicts have been iſſued in France to prevent frauds of this kind with regard to wire and laces.

GOLD-*coloured Pigments.* See PIGMENTS.

GOLD-*coloured Varniſh.* See LACQUER.

GOLD, *Crown,* See COIN and STANDARD.

GOLD, *Dutch*, is a kind of leaf uſed in gilding, &c. which is copper gilt, or braſs beaten into leaves like the genuine gold-leaf. It is ſaid to be made from copper-plates, by cementation with calamine, without ſubſequent fuſion. The thickneſs, compared with that of leaf-gold, is as nineteen to four, and under equal ſurfaces it is conſiderably more than twice as heavy as the gold.

GOLD, *Farthing of.* See FARTHING.

GOLD, *Fine* or *Pure*, is that purged by the fire of all its impurities, and all alloy. The Latins call it *aurum purum, aurum primum, aurum obrizum, aurum coctum.*

The moderns frequently call it *gold of twenty-four carats*; but, in reality, there is no ſuch thing as gold ſo very pure; and there is always wanting at leaſt a quarter of a carat. Gold of twenty-two carats has one part of ſilver, and another of copper: that of twenty-three carats has half a part, *i. e.* half a twenty-fourth of each.

Bouteroue maintains, that the electrum of the ancients was gold of nineteen carats; or four parts gold, and a fifth ſilver.

From an ordinance of king John of France, it appears that the gold then ſtruck at Paris was of nineteen carats one-fifth; and yet it is added that it was the beſt and fineſt gold then known on earth. See STANDARD.

GOLD, *Fulminating*, *aurum fulminans*, a precipitate of gold from its nitro-muriatic ſolution by ammonia, which poſſeſſes a moſt remarkable exploſive property. See AURUM.

It is prepared by diluting a ſolution of muriated gold with ſix or eight times its bulk of diſtilled water, adding drop by drop liquid ammonia, till the precipitation ceaſes; then let the yellow powder thus obtained be ſeparated by a filter, well waſhed in hot water, and afterwards dried. The fulminating gold, thus procured, will exceed the weight of the original gold by about 33 parts in 100. If a ſmall quantity, *e. g.* half a grain, of this powder be held over a candle, in a ſpoon or on the blade of a knife, it preſently explodes with a very loud report. This powder ſhould be very cautiouſly uſed; the temperature requiſite for its exploſion is ſtated at above 250 of Fahrenheit. Before it explodes, its yellow colour changes to black, and at the moment of its decompoſition an inſtantaneous flaſh is obſerved. The principal energy in exploſion is directed downwards, inſomuch that two or three grains of it exploded on a moderately thick ſheet of copper will burſt a hole in it. This ſalt is decompoſed by an electrical ſhock, but it cannot be ignited by a ſpark from electricity or from flint and ſteel. It will vehemently explode by ſudden friction, and therefore, in order to avoid dangerous accidents of this kind, it ſhould never be kept in a ground-ſtoppered bottle. The facility of its exploſion is very much increaſed by high drying; ſo that if it be heated till it becomes black, and is immediately removed from the fire, it will frequently go off by a mere touch. If the fulminating gold be mixed with four or five times its weight of chalk, or ſulphat of potaſh, or with any pulverulent ſubſtance neither fuſible nor decompoſable at a moderate temperature, and expoſed gradually to a low heat, it will be quickly decompoſed, leaving merely the purple oxyd of gold. The ſame effect may be produced by very cautiouſly heating the fulminating gold without any addition, removing it from the fire when it has changed its colour, and when cold heating it again, and proceeding in this way till the powder becomes purple, in which ſtate it will have entirely loſt its exploſive faculty. A ſimilar change occurs by melting ſulphur at the loweſt poſſible heat, and dropping in the fulminating gold by half a grain at a time, well mixing it; the ſulphur may then be burnt off without danger, and minute grains of metallic gold will be left behind. “The true theory of the decompoſition of fulminating gold was partially diſcovered by Bergman, and has ſince been fully illuſtrated by Berthollet. The former of theſe able chemiſts ſhewed that this ſalt when decompoſed in cloſe veſſels was reduced to gold, partly in the metallic ſtate and partly in that of purple oxyd, and at the ſame time a gas was extricated in bulk about a thouſand times as great as that of the original fulminating ſalt, and which extinguiſhed flame and animal life, was not abſorbed by water, and gave no precipitate with lime-water. Berthollet, by decompoſing the ſame ſubſtance in a copper tube, connected with a jar inverted in mercury, obtained azotic gas and a few drops of water, and the gold was reduced to the metallic appearance. Now as ammonia is compoſed of hydrogen and azot, and as the affinity of gold for oxygen is very ſlight, it is manifeſt that the decompoſition and exploſion, under the circumſtances already mentioned, are occaſioned by the oxygen of the gold and the hydrogen of the ammonia combining to form water, and to the liberation of the azot and its ſudden aſſumption of the gaſeous ſtate." Aikin's Dict.

Gold, *Leaf*, or *beaten gold*, is gold beaten with a hammer into exceedingly thin leaves. It is aſtoniſhing to conſider the fineneſs to which a body of gold is thus reduced. In an experiment of Reaumur's, forty-two ſquare inches and three tenths of gold-leaf weighed one grain Troy; and Mr. Boyle found that fifty and ſeven tenths weighed but a grain. As a cubic inch of gold weighs 4902 grains, the thickneſs of the gold-leaf examined by the one was the 207355th, and of that by the other only the 248532nd part of an inch. See Ductility *of Gold*.

This gold is beat on a ſmooth block of black marble, from two hundred to ſix hundred pounds in weight, and about nine inches ſquare on the upper ſurface, fitted into the middle of a wooden frame, about two feet ſquare, ſo as that the ſurface of the marble and frame form one even plane. Three of the ſides are furniſhed with a high ledge, and the front, which is open, has a leather flap faſtened to it, which the gold beater uſes as an apron, for preſerving the fragments of gold that fall off. Three hammers are employed in this buſineſs, having two round and ſomewhat convex faces: the firſt, called the cutch hammer, is about four inches in diameter, and weighs fifteen or ſixteen pounds: the ſecond, called the ſhodering hammer, weighs about twelve pounds, and is about the ſame diameter: the third, called the gold or finiſhing hammer, weighs ten or eleven pounds, and is nearly of the ſame width. The French uſe four hammers, differing both in ſize and ſhape from thoſe of our workmen.

The gold beaters alſo uſe three kinds of animal membranes; ſome of which are laid between the leaves to prevent their uniting together, and others over them to defend them from injury by the action of the hammer. For the outſide cover, they uſe common parchment made of ſheep ſkin; for interlaying with the gold, firſt, the ſmootheſt and cloſeſt vellum made of calves ſkin; and afterwards, the much finer ſkins of ox-gut, ſtript off from the large ſtraight gut ſlit open, prepared on purpoſe for this uſe, and hence called *gold-beater's ſkin*. The general proceſs of their preparation, is ſaid to conſiſt in applying one upon another, by the ſmooth ſides, in a moiſt ſtate, in which they readily cohere and unite inſeparably, ſtretching them on a frame, and carefully ſcraping off the fat and rough matter, ſo as to leave only the fine exterior membrane of the gut; beating them between double leaves of paper, to force out the remaining unctuoſity; moiſtening them once or twice with an infuſion of warm ſpices, and laſtly, drying and preſſing them. It is ſaid, that ſome calcined gypſum, or plaſter of Paris, is rubbed with a hare's foot, both on the vellum, and ox-gut ſkins, which fill up their pores, and prevent the gold leaf from ſticking. Theſe ſkins, after ſeventy or eighty repetitions, become unfit for uſe; but their virtue may be reſtored by interlaying them with leaves of paper moiſtened with vinegar or white wine, beating them for a whole day, and afterwards rubbing them over with plaſter of Paris: and even holes in them may be repaired by the dextrous application of freſh ſkins.

Gold, *the manner of preparing and beating*. They firſt melt a quantity of the pureſt gold in a black-lead crucible, with ſome borax, in a wind furnace, and pour it into an iron ingot mould, ſix or eight inches long, and ¾ of an inch wide, previouſly greaſed and heated; the bar of gold is made red-hot and forged on an anvil into a long plate, which is farther extended, by being paſſed repeatedly between poliſhed ſteel rollers, till it becomes a ribband, as thin as paper. This ribband is divided by compaſſes, and cut with ſhears into equal pieces, which are forged on an anvil till they are an inch ſquare, and afterwards well annealed. Two ounces of gold, which is the quantity melted at a time, make a hundred and fifty of theſe ſquares, ſo that each of them weighs ſix grains and two fifths; and as 4902 grains of gold make a cubic inch, the thickneſs of the ſquare pieces is about the 766th part of an inch. All theſe ſquares are interlaid with leaves or vellum, three or four inches ſquare; one leaf being laid between every two of them, and about twenty more of the leaves are laid on the outſides: over theſe is drawn a parchment caſe open at both ends, and over this another, in a contrary direction, ſo that the vellum and gold leaves are kept tight and cloſe. The whole is then beaten with the heavieſt hammer, till the gold is ſtretched to the extent of the vellum: the pieces taken out of this caſe or mould, are cut in four with a ſteel knife; and the ſix hundred pieces thus produced are interlaid, in the ſame manner, with pieces of the ox-gut ſkins, five inches ſquare. The beating is repeated with a lighter hammer, till the golden plates have acquired the extent of the ſkin; when they are divided into four, by a piece of cane cut to an edge. The whole number of leaves is then divided into four parcels, which are interlaid, as before, and beaten ſeparately, till they are ſtretched for the third time to the ſize of the ſkins. The French repeat the diviſion and beating once more. After the laſt beating, the leaves are taken up by the end of a cane inſtrument, and being thrown flat on a leathern cuſhion, are cut to a ſize, one by one, with a ſquare frame of cane made of a proper ſharpneſs, or with a frame of wood edged with cane. They are then fitted into books of twenty-five leaves each, the paper of which is well ſmoothed, and rubbed with red bole to prevent their ſticking to it. The ſize of the French gold leaves is from ſomewhat leſs than three inches to 3¾ ſquare; that of our's from three inches to 3⅕. We ſhall here obſerve, that the gold uſed for the above purpoſe is never pure, becauſe pure gold is too ductile to be worked between the gold-beater's ſkins. The neweſt ſkins will work the fineſt gold, and make the thinneſt leaf, becauſe they are the ſmootheſt. Old ſkins, being rough or foul, require coarſer gold. The fineſt gold for this purpoſe has three grains of alloy in the ounce, and the coarſeſt 12 grains. In general the alloy is ſix grains, or one eightieth part. The alloy of leaf-gold is ſilver, or copper, or both, and the colour is produced of various tints accordingly. Two ounces and two pennyweights of gold are delivered by the maſter to the workman, who, if very ſkilful, returns 2000 leaves, or 80 books, of gold, together with one ounce and ſix pennyweights of waſte cuttings. Hence one book weighs 4.8 grains; and as the leaves meaſure 3.3 inches in the ſide, the thickneſs of the leaf is one two hundred and eighty-two thouſandth part of an inch.

The French prepare what is called green gold-leaf, from a compoſition of one part of copper and two of ſilver, with eighty of gold; but Dr. Lewis obſerves, that ſuch an admixture gives no greenneſs to gold, and that this kind of leaf is made from the ſame fine gold as the higheſt gold-coloured ſort, the greeniſh hue being a ſuperficial teint given to the gold in ſome part of the proceſs: this leaf is chiefly uſed for the gilding of books. A kind of leaf, called *party-gold*, is formed by laying a thick leaf of ſilver, and a thinner one of gold, flat on one another; they are then heated and preſſed together, ſo as to unite and cohere: and being beaten into fine leaves, as in the foregoing proceſs, the gold, though only in quantity a fourth of that of the ſilver, extends over it and every where covers it.

Gold, *Million of*, a phraſe often uſed to ſignify a million of crowns.

Gold *Money*. See MONEY and COIN.

Gold, *Moſaic*, is gold applied in pannels on proper ground, diſtributed into ſquares, lozenges, and other compartments; part of which is ſhadowed to raiſe or heighten the reſt. See MOSAIC.

Gold *Plates for Enamelling* are generally made of ducat gold, whoſe fineneſs is from $23\frac{1}{2}$ to $23\frac{3}{4}$ carats: and the fineſt gold is the beſt for this purpoſe, unleſs where ſome parts of the gold are left bare and unpoliſhed, as in watch-caſes, ſnuff-boxes, &c. for which purpoſe a mixture of alloy is neceſſary, and ſilver is preferred to copper, becauſe the latter diſpoſes the plates to tarniſh, and turn green. See ENAMELLING.

Gold, *Potable, aurum potabile.* See AURUM *Potabile*, and GOLD.

Gold *Powder*, for the purpoſes of gilding, may be made by grinding gold leaf with honey, or thick gum-water, (ſee *Shell*-GOLD): by diſtilling to dryneſs a ſolution of gold in aqua regia: by evaporating the mercury from an amalgam of gold, taking care well to ſtir the maſs near the end of the proceſs with a glaſs rod or tobacco pipe; or by precipitating gold from its ſolution in aqua regia by applying to it a ſolution of common green vitriol in water, or ſome copper, &c.

Gold *Precipitate with Tin*, called alſo, from its ſuppoſed diſcoverer, *calx Caſſii*, is prepared with great care both in diſſolving the tin, and diluting the ſolution. For this purpoſe, a mixture of two parts of aquafortis, and one of ſpirit of ſalt, is ſuppoſed to be the beſt menſtruum for the tin. Into this mixture ſome fine block tin, granulated, is to be let fall, grain by grain, waiting till one grain is diſſolved before another is dropped in, that the diſſolution may go on ſlowly, without any heat or diſcharge of fumes. The gold is diſſolved in common aqua regia; and a few drops of this ſolution being mixed with ſome ounces of pure water, as many drops of the ſolution of tin are added. If the mixture changes immediately to a clear bright purpliſh red colour, the due degree of dilution has been determined; if the colour appears dull, a greater quantity of water muſt be added for the reſt of the ſolutions. After the mixture has depoſited its red matter, and become clear, a little more of the tin ſolution is to be dropped in, for diſcovering and precipitating any gold that may ſtill remain in it; the liquor being then poured off, the precipitate is waſhed and dried. Lewis's Com. Phil. Techn. p. 176. See *Ruby* GLASS.

Gold, *Queen*. See QUEEN *gold*.

Gold, *Shell*, is that uſed by the gilders and illuminers, and with which gold letters are written. It is made by grinding gold leaves, or gold beater's fragments, with a little honey, and afterwards ſeparating the honey from the powdered gold by means of water. When the honey is waſhed away, the gold may be put on paper, or kept in ſhells; whence its name. When it is uſed, it is diluted with gum-water, or ſoap-ſuds. The German gold-powder, prepared from the Dutch gold leaf in the ſame manner, is generally uſed, and when it is well ſcoured with varniſh, anſwers the end in japanner's gilding, as well as the genuine. See GILDING.

Gold-*ſize* for burniſhed gilding, is prepared of one pound and a half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of ſweet oil, and three drams of pure tallow; grind the clay, chalk, and black-lead ſeparately, very fine in water; then mix them together; add the oil and tallow, and grind the mixture to a due conſiſtence; or it may be more ſimply prepared by grinding together ſome ſtrongly calcined red ochre with the thickeſt and oldeſt drying oil that can be procured; and, previouſly to uſe, mixing it with a little oil of turpentine for giving it a proper conſiſtence. See *Oil* GILDING.

Gold-*ſize of Japanners* may be made by pulverizing gum animi and aſphaltum, of each one ounce; red-lead, litharge of gold, and umbre, of each one ounce and a half, mixing them with a pound of linſeed oil, and boiling them, obſerving to ſtir them till the whole be incorporated, and appears, on growing cold, of the conſiſtence of tar; ſtrain the mixture through a flannel, and keep it ſtopped up in a bottle, for uſe. When it is uſed, it muſt be ground with as much vermilion as will give it an opaque body, and diluted with oil of turpentine, ſo that it may be worked freely with the pencil. A ſimple preparation conſiſts of one pound of linſeed oil, and four ounces of gum animi; powder the gum, and mix it gradually with the boiling oil: let it continue to boil, till it becomes of the conſiſtence of tar; ſtrain it through a coarſe cloth, keep and uſe it as the other.

Gold-*ſmith*, or as ſome chooſe to expreſs it, *ſilver-ſmith*, the artiſt who makes veſſels, utenſils, and ornaments in gold or ſilver. The goldſmith's work is either performed in the mould, or beat out with the hammer or other engine. All works that have raiſed figures are caſt in moulds, and afterwards poliſhed and finiſhed; plates or diſhes of ſilver or gold are beat out from thin flat plates, and tankards and other veſſels of that kind are formed of plates ſoldered together, and their mouldings are beat, not caſt. The buſineſs of the goldſmith formerly required much more labour than it does at preſent, for they were obliged to hammer the metal from the ingot to the thinneſs they wanted: but there are now invented flatting-mills, which reduce metal to the thinneſs that is required, at a very ſmall expence. The goldſmith is to make his own moulds, and for that reaſon ought to be a good deſigner, and have a taſte in ſculpture: he alſo ought to know enough of metallurgy to be able to aſſay mixed metals, and to mix the alloy.

The goldſmith in London employs ſeveral hands under him for the various articles of his trade. In this great city there are always hands that excel in every particular branch of the trade, and there is commonly employment enough for every one in his particular branch. The jeweller, the ſnuff-box and toy-maker, the ſilver turner, the gilder, the burniſher, the chaſer, the refiner, and the gold-beater, are all employed by and under the goldſmith.

Gold-*ſmith, Company of, in London.* See COMPANY.

Gold *Thread*, or *ſpun gold*, is a flatted gilt wire, wrapped or laid over a thread of yellow ſilk, by twiſting it with a wheel and iron bobbins. By means of a curious but complex machinery, a number of threads is thus twiſted at once by the turning of one wheel. The principal art conſiſts in ſo regulating the motion, that the ſeveral circumvolutions of the flatted wire, on each thread, may juſt touch one another, and form, as it were, one continued covering. At Milan, it is ſaid, they make a ſort of flatted wire, gilt only on one ſide, which is wound upon the thread, ſo that only the gilt ſide appears. There is alſo a gilt copper wire, made in the ſame manner as the gilt ſilver, chiefly at Nuremberg: and the ordinances of

France require it to be ſpun on flaxen or hempen threads. The Chineſe, inſtead of flatted gilt wire, uſe ſlips of gilt paper, which they interweave in their ſtuffs, and twiſt upon ſilk threads.

Gold, *Tun of*, is a kind of money of account, formerly uſed by the Dutch, and in ſome other countries, containing a hundred thouſand florins.

A hundred pounds of, or in, gold, is found to weigh two pounds ten ounces: the ſum in ſilver weighs twenty-ſix pounds four ounces. Twenty-two pence in copper farthings and half-pence, weigh one pound avoirdupois. A tun of gold, at 4*l.* the ounce, amounts to 96,000*l.* A tun of ſilver, at 5*s.* 2*d.* the ounce, to 6200*l.* A pound ſterling of gold to 48*l.* An ounce is worth 4*l.* The penny-weight 4*s.* One grain, 2*d.* A pound of ſterling ſilver amounts to 3*l.* 2*s.* An ounce is worth 5*s.* 2*d.* The penny-weight, 3*d.* and ſomething more; one grain a half-penny. A pound of ſilver avoirdupois comes to 3*l.* 5*s.* 3*d.* half-penny.

Gold, *Virgin*, is pure gold, juſt as it is taken out of the mines, before it has undergone any action or preparation of fire; whence the Greeks call it απυρος.

Such is the αμμοχρυσος, or gold-duſt, and that got by lotion in the lavaderos in Chili: it is added, that there are maſſes or lumps of pure gold found in the mines, particularly thoſe of Hungary. Accordingly, in the emperor's collection, are ſtill preſerved ſeveral plates of gold, ſaid to have been thus found.

Virgin gold is ſometimes very pale, and ſo ſoft, that it may be moulded into any figure with the hand; it even takes an impreſſion from a ſeal, like the ſofteſt wax. To harden it, as alſo to heighten its colour, they mix emery with it.

Gold, *White*. See Platina.

Gold *Wire* is a cylindrical ingot of ſilver, above an inch thick, two feet in length, and weighing about twenty pounds, ſuperficially gilt, or covered with gold at the fire, and afterwards drawn ſucceſſively through a great number of little round holes of a wire-drawing iron, each leſs than the other, till it be ſometimes no bigger than a hair of the head. There is very little wire made entirely of gold, and this chiefly for one particular purpoſe, that of filligree work.

It is amazing to what degree of fineneſs the gold is here drawn; and yet it ſtill keeps firm together, and never ſhews the leaſt ſigns of the ſilver underneath it. The reader may ſee a computation hereof, as alſo a more particular account of the manner of proceeding, under the article Ductility *of gold*.

Gold *Wire flatted*, is the former wire flatted between two rollers of poliſhed ſteel, to fit it to be ſpun in ſilk, or to be uſed flat as it is without ſpinning, in certain ſtuffs, laces, embroideries, &c.

Manner of forming Gold Wire and Gold thread, both round and flat.—The firſt object, which is of the utmoſt conſequence, is the choice of the pureſt gold; for on this chiefly depends the beauty and durability of the colour of the laces, brocades, and other commodities prepared from it. To a difference in this reſpect, the boaſted ſuperiority of the French laces to the generality of thoſe made in England, till of late, has been wholly owing. With regard to the ſilver that forms the body of the wire, it is ſaid that there is an advantage in its being alloyed. The French ſilver for gilding is ſaid to be alloyed with five or ſix penny-weight, and ours with twelve penny-weight of copper, in the pound Troy. The gold is employed in thick leaves, which are applied all over the ſilver rod, and preſſed down ſmooth with a ſteel burniſher. Several of theſe leaves are laid over one another, as the gilding is required to be more or leſs thick. The ſmalleſt proportion allowed by act of parliament, is 100 grains of gold to a pound, or 5760 grains of ſilver. The largeſt proportion for the beſt double gilt wire was formerly 120 grains to a pound; but the proportion of gold has been of late increaſed to about 140 grains. The firſt part of the drawing proceſs, as well as the preparation and gilding of the ſilver rod, is performed by the refiner, who uſes plates of hardened ſteel, with a piece of tough iron welded on the back, to prevent the ſteel from breaking. The holes in theſe plates are conical, being larger in the back part than in the ſteel, that the rod may not be ſcratched againſt the outer edge, and that they may contain bees-wax, which makes the rod paſs more freely, and preſerves the gold from being rubbed off. One end of the rod, made ſmaller than the reſt, is puſhed through a hole that will admit it, when the plate has been properly ſecured, and laid hold of by ſtrong pincers, called clamps, adapted to the purpoſe; to theſe pincers, which are ſo contrived, that the force which pulls them horizontally, ſerves at the ſame time to preſs them together, a rope is faſtened by one end, and the other end goes round a capſtan with croſs bars, which requires the ſtrength of ſeveral men to turn it. The rod, thus drawn through, is well annealed; it is then paſſed through the next hole; and the annealing and drawing are repeated, till, being reduced to about the ſize of a large quill, it is delivered in coils to the wire-drawers. The remainder of the proceſs requires plates of a different quality, which are brought from Lyons in France, and are formed of a metallic maſs, whoſe prevailing ingredient is iron: the holes are drilled in them here. Theſe plates are of two ſorts; ſome of conſiderable thickneſs, for the wire in its larger ſtate, and others about half as thick, for the finer wire. In the uſe of theſe plates, furniſhed with a variety of holes, the dexterity of the workman principally conſiſts in adapting the hole to the wire: for this purpoſe he uſes a braſs plate, called a ſize, on which is meaſured, by means of notches, like ſteps cut at one end, the increaſe which a certain length of wire ſhould gain in paſſing through a freſh hole; and if the wire is found to ſtretch too much or too little, the hole is widened or contracted. Slits of different widths, in thick poliſhed iron rings, ſerve alſo as gages for meaſuring the degree of fineneſs of the wire.

The wire-drawer's proceſs begins with annealing the large wire received from the refiner, which he does, by placing it, coiled up, on ſome lighted charcoal, in a cylindrical cavity, called the pit, under a chimney, and throwing more burning charcoal over it. When it is cooled by being quenched in water, one end is paſſed through the firſt hole in the thick plate, and faſtened to an upright wooden cylinder ſix or eight inches in diameter; in the top of which are two ſtaples, and through theſe is paſſed the long arm of a handle, by which the cylinder is turned on its axis by ſeveral men. By this proceſs, called *degroſſing*, the wire is frequently annealed and quenched, after paſſing through every hole, or every other hole, till it is brought to about the ſize of the ſmall end of a tobacco pipe, and then cut into portions for the fine wire-drawer. In this laſt part of the wire-drawing proceſs, annealing is not neceſſary, but the wire is waxed at every hole. The contrivance for drawing the wire through the plate in this caſe, when leſs force is needful, is a kind of a wooden wheel placed horizontally, having in its upper ſurface ſmall holes at different diſtances from the axis, into one or other of which, according to the force required, is inſerted the end of an upright handle, whoſe upper end is received in a hole made in a croſs bar above. From this the wire is wound off upon a ſmaller cylinder, called a rochett, placed on the ſpindle of a ſpinning-wheel; and this cylinder being placed behind the plate, the wire is again drawn through upon the firſt, and being brought to the proper fineneſs, it is annealed for the flatting-mill. In this annealing, the wire is wound on a large hollow copper bobbin, ſet upright, including ſmall-coal, and encompaſſed with lighted charcoal or ſmall-coal, communicating a gradual heat. The wire, in this ſtate, muſt be watched and removed from the heat, when it appears of the proper colour. The next operation is that of the flatting-mill, which conſiſts of two perfectly round and exquiſitely poliſhed rollers, formed internally of iron, and welted over with a plate of refined ſteel: theſe rollers are placed with their axes parallel, and their circumferences nearly in contact; they are both turned with one handle; the lowermoſt is about ten inches in diameter, the upper little more than two, and their width or thickneſs is about an inch and a quarter. Theſe rolls are ſometimes repoliſhed with putty, prepared by calcining a mixture of lead and tin. The wire, unwinding from a bobbin, and paſſing between the leaves of a book gently preſſed, and through a narrow ſlit in an upright piece of wood, called a ketch, is directed by a ſmall conical hole in a piece of iron, called a guide, to any particular part of the width of the rollers, ſome of the beſt of which are capable of receiving, by this contrivance, forty threads. When the wire is flatted between the rollers, it is wound again on a bobbin, which is turned by a wheel, fixed on the axis of one of the rolls, and ſo proportioned, that the motion of the bobbin juſt keeps pace with that of the rolls. Dr. Halley ſtates that ſix feet in length of the fineſt gilt wire before flatting will counterpoiſe no more than a grain; and as the gold is not quite 1-57th of the whole, a ſingle grain of gold thus extended will be 345.6 feet long. By flatting, the length of the wire is increaſed about one-ſeventh, and its weight is equal to 1-96th of an inch; hence the ſurface occupied by one grain is equal to 98.7 ſquare inches, with a thickneſs of 1-490444th of an inch. (See Ductility.) See on the ſubject of the preceding articles, Macquer's Dict. of Chemiſtry, Eng. edit. 1777. and particularly Dr. Lewis's Philoſophical Commerce of Arts, *paſſim.* See alſo Aikin's Dictionary.

Gold, in *Medicine* and *Chemiſtry*. The chemiſts make ſeveral preparations of gold for medicinal uſes; as ſalts, mercuries, and tinctures of gold; but it is a point not yet well agreed on, whether gold has any real property whereby it may be of uſe in medicine.

Some mechanical phyſicians have had a notion, that if the particles of gold could be rendered fine enough, ſo as to circulate with the blood, that it would prove more effectual in the cure of diſeaſes than mercury. But this is a mere hypotheſis. The *aurum fulminans* has been uſed, and other preparations of gold are to be met with in authors; but they ſeem to meet with little credit among modern practitioners.

Gold, in *Heraldry*, is one of the metals, more uſually called by the French name, Or.

Gold-*finch*, in *Ornithology*, is the Fringilla *carduelis* of Linnæus; which ſee.

Gold-*fiſh*, in *Ichthyology*, is the Cyprinus *auratus* of Linnæus; which ſee.

Gold-*fiſh* is alſo a name by which ſome authors have called the *alauſa*, *aloſa*, or *ſhad*, from the yellow colouring it frequently has on the covering of the gills. See Clupea *Aloſa.*

Gold *of Pleaſure*, in *Botany*. See Myagrum.

Gold *Coaſt*, or, as it is ſometimes called, *Guinea proper*, a country of Guinea, on the S.W. coaſt of Africa, bordering on that part of the Atlantic which is called the gulf of Guinea, and extending between three and four degrees from the river Ankobar, or, as others ſay, from the Coſta, or the Aſſinoe, to the Volta, and deriving its name from the quantity of gold which it produces. It is bounded on the north by Kongo or Congo, on the eaſt by the Slave coaſt, on the weſt by the Ivory coaſt, and on the ſouth by the gulf of Guinea. It comprehends a number of petty ſtates or kingdoms, *viz.* Adomir, called likewiſe Saku and Avena, Axim, Ankobar, Adom, likewiſe called Little Inkaſſan, or Warſher, Jabi or Jabo, Commendo or Guaſſo, Fetu, Sabo, Fantin, Acron, Agonna or Anguirra, Amra or Aquamboe, Lableade, and Ningo or Lambi. Each of theſe provinces or kingdoms contains one, two, or more towns or villages on the ſea-coaſt, between, or under the European forts and ſettlements. Eight of theſe are real monarchies, having their own proper kings; the reſt are republics, governed by magiſtrates, who are ſubject to the laws and periodical changes. Upon the river Ankobar, or Cobre, which ſome reckon the firſt proper county of the Gold Coaſt, there is a number of towns, which compoſe three different provinces of Ankobar or Ancober, Aborrel or Abocro, and Eguira, at which latter place the Dutch had formerly a fort, and carried on a conſiderable trade in gold. Eight leagues E. of cape Apollonia ſtands the town of Axim, called by ſome Achembone. (See Achembone and Axim.) See Acron, Adom, Adomir, Anta, Commendo, &c. &c. The country throughout the Gold Coaſt abounds in hills, adorned with high and beautiful trees, among which are the palm, the cocoa-nut, the papay, and the banana. The vallies between the hills are wide and extenſive, and fit for the plantation of all ſorts of fruit; and if they were as well cultivated as watered, they would ſupply half the coaſt with proviſions. The ſoil produces in great abundance very good rice, the richeſt ſort of millet with red grain, yams, potatoes, and other roots, all good in their kind. The ſugar-cane grows here plentifully, and larger than any where elſe on the Coaſt of Guinea. Palm-wine and oil are very good, and very abundant; the country alſo has plenty of tame cattle and wild beaſts. The domeſtic animals are bulls, cows, ſheep, and goats, the laſt of which are numerous and their fleſh is excellent; neither the mutton nor beef is good; but of all animal food dog's fleſh is moſt preferred by the negroes. The wild animals are elephants, tygers, jackalls, boars, deer of various ſizes, cats, porcupines, monkies, rats, mice, &c. &c. Among the birds are pheaſants, parrots, maccaws, turtle-doves, and ſeveral others. The reptiles are numerous; ſuch as ſnakes, ſerpents, vipers, lizards, ſcorpions, ſpiders, &c. The coaſts, lakes, and rivers abound with fiſh, and likewiſe with alligators and gunas, an amphibious animal, reſembling the crocodile, and four feet in length. The climate is very hot from October to March, but during the other months tolerable. The natives are generally healthy; but to Europeans the climate is inſalubrious, and often fatal, eſpecially in the months of July and Auguſt.

It is obſerved that of all the countries on the coaſt of Weſtern Africa, the Gold Coaſt experiences the moſt intenſe heat. Iſert, a modern traveller, near Rio Volta, has ſeen Fahrenheit's thermometer as high as 95½ in his chamber, and 134° in the open air; ſurpaſſing by 26° the greateſt heat obſerved by Adanſon on all the banks of the Senegal. Although this traveller advanced only 10 miles from Chriſtianburg on this coaſt, his journey is curious.

The countries he viſited during his ſhort excurſion in the interior, are repreſented as very beautiful, fertile, and populous; they are, in general, woody, but, nevertheleſs, more healthy than the ſhores; they are agreeably intermingled with mountains, vallies, and hills. Freſh water, which is ſcarce and bad on the coaſt, is here excellent and abundant. About five miles from Chriſtianburg Iſert obſerved a chain of mountains covered with tall trees, and compoſed of large grained granite, of gneiſs, and of quartz.

The native negroes of the Gold Coaſt are in general tall, ſtraight, and well-proportioned, with oval faces, ſparkling eyes, regular, white teeth, mouths of a moderate ſize, and lips tinged with a better colour and thinner than thoſe of the negroes of Angola. As to the qualities of the mind, they have a quick apprehenſion and ready memory, accompanied with an aſtoniſhing preſence of mind, and equanimity; but they are generally ſo indolent that mere neceſſity puts them upon exerting the faculties they poſſeſs. In general, they are crafty, fraudulent, and treacherous; thieves, gluttons, and drunkards, and equally incontinent and covetous. When they obtain a victory over their enemies, they return home dancing and ſinging, and when defeated do the ſame round the graves of their friends and fellow-ſoldiers. Alike inſenſible of grief or joy, they ſing till they die, and dance into the grave. The women are proportionably handſomer than the men, ſtraight, ſlender, and well-limbed; their cheſts high, their mouths ſmall, and their eyes indicating vivacity and ſpirit. They are quick, cheerful, and loquacious; gay in their diſpoſition, and looſe in their principles as to gallantry, but temperate in their diet. When the men and women overcome their natural indolence, they are laborious, induſtrious, and ingenious; and apply with activity and diligence to agriculture or fiſhing, ſo far as they are excited by poverty or avarice. Their dreſs is various according to their rank and circumſtances; but the rage of dreſs is chiefly prevalent among the women, who are fond of adorning all parts of their bodies with gold, coral, and ivory trinkets; and this rage they derived from the Portugueſe and Dutch; as before their arrival men and women went naked to the age of maturity. They are fond of frequent ablutions, and being accuſtomed to the uſe of water, they are excellent ſwimmers and divers from their youth. Beſide the natural inhabitants of the Gold Coaſt, there is a great number of Mulattoes, a mixed progeny, ariſing from the commerce of Europeans with the black women. This ſpurious race forms gangs of thieves and plunderers, void of decency, honour, honeſty, or principle in their dealings with each other, with the Negroes, or the Europeans. Theſe call themſelves Chriſtians, although they are the groſſeſt of all idolaters, and moſt of their women proſtitute their bodies publicly to Europeans, and privately to the Negroes. The towns and villages of this coaſt conſiſt of a multitude of little huts or cabins, diſperſed in groups, without order or deſign, and communicating with each other by narrow crooked roads, which terminate in the centre of the town or market place.

It is obſervable that the further you remove from the ſea-coaſt, the more civilized do the natives appear, at leaſt ſo far as relates to their mode of building and of living. The common food of the Negroes, in this part of Africa, is a pot of millet boiled to the conſiſtence of bread, yams, and potatoes, over which they pour ſome palm-oil, and garniſh the diſh with herbs and putrid fiſh. This is their meſs on common days; and on holidays they feaſt upon beef, mutton, and fowls. They begin the day with drinking brandy, and conclude the evening with palm-wine, mirth, riot, and tobacco, of which they are extravagantly fond. In eating they are temperate, but very profuſe in drinking. Their marriages are encumbered with few ceremonies, and without any previous courtſhip; and they are as eaſily diſſolved as contracted. Polygamy is allowed among them; and the women are generally doomed to the moſt laborious offices; they are obliged to cultivate the ground, ſow millet, plant yams, and provide ſubſiſtence for the huſband, who is idly ſpending his time in goſſiping, drinking, and ſmoaking. The rich, however, have two wives, who are exempted from labour and all ſervile employments; and to them the management of the houſe is intruſted, and a ſort of authority over all the other women is committed. It is ſaid to be no uncommon expedient among Negroes to marry, in order to obtain a livelihood by the proſtitution of their wives. As the wealth of the Negroes conſiſts chiefly in the number of their family, they are anxious for multiplying their children; and a pregnant woman is treated with great tenderneſs and reſpect. A child, as ſoon as it ſees the light, is conſecrated by the prieſt, and has three names given to it. Circumciſion, it is ſaid, though practiſed in other parts of Africa, is hardly known on the Gold Coaſt, except at Acra, where it is performed at the time of baptiſm or conſecration. Beſides their lawful wives, the Negroes often keep concubines, who are preferred to their wives, and more tenderly treated; nevertheleſs their children are reckoned illegitimate. But legitimate children never inherit any paternal fortune, in any kingdom on the Gold Coaſt, except at Acra. In the countries of Eguira, Axim, Ancobar, Anta, and Adom, there are certain women who never marry, but are dedicated by profeſſion to the public uſe, and initiated in their vocation in a formal manner. Among the Negroes there is a variety of mechanical arts, in which they are expert; ſuch as the making of wooden and earthen veſſels and plates, chair-mattings, copper ointment boxes, bracelets, necklaces, rings, and ear-rings of gold, ſilver, or ivory; and alſo all ſorts of weapons and inſtruments of war. Their tools, which are rude and ſimple, conſiſt only of a ſtone for an anvil, a pair of tongs, a pair of bellows, a file, a ſaw, and a hammer. They can finiſh with extraordinary exactneſs ſteel-wire, and materials of gold, braſs, and copper. In building canoes, which are of various ſizes, from 30 to 14 feet in length, and three or four feet in breadth, the Negroes are very ingenious, and they are no leſs dextrous in the uſe of them. With regard to the huſbandry of the Negroes, they ſow in the rainy ſeaſon, the ſoil at other times being unmanageably hard: and they adapt their ground to the nature of the grain; ſowing maize in elevated and dry ſituations, and rice or millet in low marſhy lands, ſubject to inundations. The natives of the coaſt, finding it eaſy to diſpoſe of all their grain, have eſtabliſhed corn markets in every village, and the price of grain, in gold-duſt, cowries, &c. is rated by certain officers of police, appointed by the king. Hither the men and women meet from conſiderable diſtances, bearing heavy burdens; and the women eſpecially ſubmit to great labour and fatigue in this way, that they may exchange their heavy loads for European commodities, ſuch as looking-glaſſes, bracelets, ear-rings, glaſs-beads, and other female trinkets, ſuited to their taſte for dreſs and finery. The markets are exempted from all duties and impoſts. Beſides theſe frequent markets, they have alſo fairs twice a year for European wares. All the diverſions among the Negroes conſiſt of dances, to which they are exceſſively addicted, muſic, and mock combats, which often terminate tragically. The principal muſical inſtruments among the Negroes are horns, made of ivory, trumpets, drums of different ſizes, and a kind of harp, with ſix or eight ſtrings.

The honour of the firſt diſcovery of the Gold Coaſt is conteſted between the French and Portugueſe; the French pretend that they were acquainted with Nigritia and Guinea above 100 years before the Portugueſe began their diſcoveries, or about the year 1346 or 1364, but little credit is attached to theſe accounts of French writers. The Portugueſe, it is ſaid, fitted out a ſhip at Liſbon, under the protection of Don Henry, for the ſole purpoſe of making diſcoveries along the coaſt of Africa. At this time Alphonſo I. reigned in Portugal. The navigators, it is further ſaid, were driven on an iſland in the gulf of Guinea, which they called St. Thomas, and where they made a long ſtay, laying the firſt foundation of a colony in this iſland. Having repaired their veſſel, they returned to Liſbon, and arrived there in 1454. The Portugueſe ſoon equipped a fleet, and puſhed their diſcoveries as far as Benin, and in proceſs of time arrived in the road of Acra, on the Gold Coaſt, where they procured a quantity of gold. A number of adventurers from the iſland of St. Thomas arrived at Elmina four years after the departure of the French. Purchas relates, that Alphonſo, having little leiſure for purſuing diſcoveries towards the latter end of his reign, gave an excluſive privilege for five years to Fernando Gomez, a citizen of Liſbon, to ſail to the coaſt of Africa: and a perſon, deputed by him, ſays Purchas, diſcovered Elmina; and during this period, were alſo diſcovered the iſlands of St. Thomas, St. Matthew, Annobon, and del' Principe. In 1481 John II. encouraged the commercial ſpirit of his ſubjects, and projected further diſcoveries; and it was probably upon this occaſion, notwithſtanding the aſſertions of French writers, that fort St. George de la Mina, or Elmina, had its firſt riſe. John, the ſucceſſor of Alphonſo, conferred many privileges on this new colony. A few years after, the ſame prince eſtabliſhed a Guinea company, with excluſive privileges. In the reign of Henry III. of France, after the termination of the civil wars, the French began to renew their voyages to the Grain and Gold Coaſt. From this period the credit of the Portugueſe began to decline, and other Europeans began to open a commerce with the Coaſt of Guinea. Among others the Dutch engaged in the warfare, which had been proſecuted between the Portugueſe and other Europeans; and by perſeverance they made themſelves maſters of the forts of Elmina and Axim; obtaining, by their courage, that ſecurity, which the Portugueſe had loſt by their inſolence and cruelty. The firſt Dutchman who led the way to Guinea, was one Bernard Erick, in 1595. Running along the Gold Coaſt, he eſtabliſhed a correſpondence with the natives, treated them with civility, and alienated their affections from the Portugueſe. At length, by their intrigues with the king of Sabo, the Dutch obtained permiſſion to build a fort, three leagues E. of Cabo Corſo, or Cape Coaſt. This fort was finiſhed in 1624, and the Dutch power founded in Guinea, at the time when the States were engaged in a war with Philip IV. of Spain. In the year 1637 they ſucceeded, after much reſiſtance, in taking the fort of St. George d'Elmina, and in the year 1642 the fort of Axim alſo fell into their hands. The Dutch, having thus far been ſucceſsful, proceeded to attack the Engliſh ſettlements. In tracing the firſt Britiſh eſtabliſhments on the Coaſt of Guinea, we may begin with obſerving, that a trade here had been carried on by ſome private adventurers, without the aid or protection of the government. In 1585 and 1588, queen Elizabeth granted two patents to certain rich merchants of England; one for an excluſive trade to the coaſt of Barbary, and another for that of Guinea. In 1592 a third patent was obtained by the ſame body of merchants. In 1651 the republic of England encouraged the African trade; and in 1662 Charles II. granted a charter to a body of merchants, under the name of the Royal Company of England trading to Africa, extending their limits from the mouth of the Straits to the Cape of Good Hope. The affairs of this company falling into diſorder, the king erected another corporation, called the "Royal African Company," which has ſubſiſted to this day. This charter bears date, Sept. 27, 1672. This company, with a ſmall capital, was diligent and ſucceſsful; Cape Coaſt was enlarged and beautified; the forts of Acra, Dixſcove, Winebaw, Sukkonda, Commendo, and Anamaboa, were built or repaired, all of them on the Gold Coaſt, and ſeveral within muſket-ſhot of the Dutch ſettlements. They bought Frederickſburg of the Danes, and built a new fort in Whidah. See *African* COMPANY.

GOLD *Cronach*, a town of Germany, in the principality of Bayreuth, which had formerly a gold mine; 5 miles N. of Bayreuth.

GOLDAPP, a town of Pruſſian Lithuania; 68 miles E. S. E. of Konigſberg.—Alſo, a river of Pruſſia, which runs into the Rominte; 6 miles N. of Goldapp.

GOLDAST, MELCHIOR HEIMENSFELD, in *Biography*, a learned writer of the 16th century, was a native of Switzerland. He ſtudied the civil law at Altdorf, but he is better known as a man of letters. His works, though not marked for originality, were highly eſteemed by the learned of the period in which he flouriſhed: the principal of theſe are, 1. "Monarchia Sancti Imperii Romani," in three volumes folio, publiſhed in 1611-14. Theſe volumes conſiſt of a collection of treatiſes on the civil and eccleſiaſtical juriſdiction of the empire. "Alemaniæ Scriptores," three volumes folio, 1730. "Commentarius de Bohemiæ Regno," 4to. "Informatio de ſtatu Bohemiæ quoad Jus," 4to. "Sybilla Francica," being a quarto collection of pieces relative to the maid of Orleans: "Scriptores Rerum Suevicarum." "Collectio Conſuetudinum et Legum Imperialium." "Politica Imperialia," and a collection of letters, written to him by ſeveral men of learning. This laſt work was printed at Frankfort in 1688. Mr. Goldaſt was of a capricious temper and of changeable habits, which prevented him from riſing in the world. He died in 1635, having long ſtruggled with poverty. Moreri. Bayle.

GOLDBERG, in *Geography*, a town of Sileſia, in the principality of Lignitz, deriving its name from a gold-mine in its vicinity, which was formerly very rich. The earth, called ſigillata terra, is dug near it; and the inhabitants are employed in the woollen and linen manufactures; 12 miles S.W. of Lignitz. N. lat. 51° 4'. E. long. 15° 53'.—Alſo, a town of the duchy of Mecklenburg; 15 miles E. of Wiſmar.

GOLDECK, a town of the archbiſhopric of Salzburg; 28 miles S. of Salzburg.

GOLDEN, ſomething that has a relation to gold, or conſiſts of gold, is valuable like gold, or the like.

GOLDEN *Bull*, *Bulla Aurea*. See BULL.

GOLDEN *Calf* was a figure of a calf, which the Iſraelites caſt in that metal, and ſet up in the wilderneſs to worſhip, during Moſes's abſence in the mount, and which that legiſlator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of, as related Exod. xxxii.

The commentators have been greatly divided on this article: the pulverizing of gold, and rendering it potable, is an operation in chemiſtry of the laſt difficulty; and it is hard to conceive how it ſhould be done at that time, before chemiſtry was ever heard of, and in a wilderneſs too! Many, therefore, ſuppoſe it done by a miracle; and the reſt, who allow of nothing ſupernatural in it, advance nothing but conjectures as to the manner of the proceſs.

Moſes could not have done it by a ſimple calcination, nor amalgamation, nor antimony, nor calcination: nor is there one of thoſe operations that quadrates with the text.

Mr. Stahl has endeavoured to remove this difficulty. The method Moſes made uſe of, in making his *aurum potabile*, according to this author, was the ſame with that which now obtains; only, inſtead of tartar, he made uſe of the Egyptian natron, which is common enough throughout the Eaſt.

Golden *Cape*, in *Geography*, a cape of England, on the W. coaſt of Dorſetſhire. N. lat. 50° 43′. W. long. 2° 50′.

Golden *Cups*, a name by which ſome call the ranunculus, or crow-foot.

Golden *Eye*, in *Ornithology*, the Anas *Clangula*. See Duck.

Golden *Eye*, a ſpecies of fly. See Chrysopis.

Golden *Fleece*, in the *Ancient Mythology*. See Argonautic.

Golden *Fleece*, *Order of the*, is a military order, inſtituted by Philip the Good, duke of Burgundy, in 1429.

It took its denomination from a repreſentation of the golden fleece, borne by the knights on their collars, which conſiſted of flints and ſteels. The king of Spain is now grand maſter of the order, in quality of duke of Burgundy: the number of knights is fixed to thirty-one.

It is uſually ſaid to have been inſtituted on occaſion of an immenſe profit which that prince made by wool; though others will have a chemical myſtery couched under it, as under that famous one of the ancients, which the adepti contend to be no other than the ſecret of the elixir, written on the fleece of a ſheep.

Golden *Flower*, in *Botany*. See Chrysanthemum.

Golden *Flower-gentle*, a name ſometimes given to ſeveral ſpecies of the amaranth.

Golden *Head*, in *Ornithology*, a water-fowl, otherwiſe called *anas arctica*. See Duck.

Golden *Iſland*, in *Geography*, a ſmall iſland at the entrance of the gulf of Darien, in Terra Firma, S. America. N. lat. 8° 20′. W. long. 72° 32′.

Golden *Lake*, a lake of the iſland of Borneo. N. lat. 3° 55′. E. long. 115° 45′.

Golden *Lung-wort*, in *Botany*. See Hieracium.

Golden *Maiden-hair*. See Adiantum *aureum*, and Polytrichum.

Golden *Mouſe-ear*. See Hieracium.

Golden *Number*, in *Chronology*. See Cycle *of the Moon*, and Number.

Golden *Prebendary of Hereford*. See Prebendary.

Golden *River*, in *Geography*, a river of America, which runs into the Miſſiſippi, N. lat. 43° 20′. W. long. 92° 2′.

Golden *River*, or *Rio del Oro*, a river of America, which runs into the Spaniſh Main, N. lat. 14° 44′. W. long. 82° 55′.

Golden *Rod*, or *Saracen's Wound-wort*, *virga aurea*, in *Botany*. See Solidago.

Golden *Rod Tree*. See Bosea.

Golden *Rule*, in *Arithmetic*, a rule or praxis of great uſe and extent in the art of numbers, whereby we find a fourth proportional to three quantities given. The Golden Rule is alſo called the Rule of Three and Rule of Proportion. See its nature and uſe under the article Rule *of Three*.

Golden *Samphire* is a ſpecies of the inula or elecampane. (See Inula.) It grows naturally on the ſea-coaſts in many parts of England, and is ſometimes ſold in the London market for the true ſamphire, though entirely deſtitute of its warm aromatic taſte. See Samphire.

Golden *Saxifrage*. See Chrysoplenium.

Golden *Stole*, *order of the*. See Stole.

Golden *Sulphur of Antimony*. See Antimony.

Golden *Thiſtle*, in *Botany*. See Scolymus.

GOLDENSTEIN, in *Geography*, a town of Moravia, in the circle of Olmutz; 32 miles from Olmutz.

GOLDENSTETT, a town of Germany, in the country of Diepholz; 11 miles N. of Diepholz.

GOLDENTRAUN, a town of Upper Luſatia; 16 miles S.E. of Gorlitz. N. lat. 50° 27′. E. long. 15° 26′.

GOLDINGEN, a town of the duchy of Courland, ſituated near the river Weta, defended by an old caſtle, and containing two churches; 48 miles W.N.W. of Mittaw. N. lat. 56° 51′. E. long. 21° 44′.

GOLDLAUTER, a town of Germany, in the county of Henneberg, 12 miles N.E. of Meinungen.

GOLDMAN, Nicholas, in *Biography*, a mathematician, was born at Breſlaw, in Sileſia, in the year 1623, and died at Leyden in 1665. The works by which he is generally known are "Elementa Architecturæ Militaris," 1643. "De Uſu Proportionarii Circuli." "De Stylometricis," 1662, and another treatiſe "On Architecture," publiſhed in 1696, with numerous engravings, and the life of the author. Moreri.

GOLDONI, Charles, was born at Venice in the year 1707. Almoſt from his infancy he gave indication of a humorous character, and a propenſity to dramatic performances. Before he could well read he became an author, and wrote the plan of a comedy by the time he was eight years old. This piece poſſeſſed ſo much merit, that it required the teſtimony of reſpectable witneſſes to verify its being the production of a child. He received the elements of education at Venice, from this city he went to the Jeſuits' college at Perugia to ſtudy rhetoric, and afterwards he ſtudied philoſophy at Rimini. His mind was, however, too deeply engaged in theatrical exhibitions to make the ſyſtem of Ariſtotle a predominant purſuit. Every leiſure moment he ſpent at the theatre, till at length he paſſed from the pit to the ſtage, and joined a company of players. This, by his own account, was an error, which drew after it many ſerious conſequences. He had been intended by his father for the profeſſion of phyſic, which he was unable to ſtudy: he was then ſolicited to prepare himſelf for the bar, and was engaged, after many changes, in practice at the courts of Venice. After this he was appointed ſecretary to the Venetian reſident at Milan, where he became acquainted with the manager of the theatre, and wrote a farce for him, entitled "The Venetian Gondolier," which was performed and printed: by degrees he became united to the company, and compoſed many pieces for them. He now turned his thoughts towards reforming the Italian ſtage, and ſo earneſt was he in his projects, that it is ſaid in a ſingle year he wrote ſixteen new comedies, beſides forty-two other pieces for the theatre, and among theſe are reckoned ſome of his beſt productions. The firſt edition of his works was publiſhed in 1753 in 10 vols. 8vo. After this he publiſhed many additional pieces under the title of the "New Comic Theatre." He had compoſed 59 other pieces ſo late as the year 1761, and here cloſes the literary life of Goldoni in Italy. He now repaired to Paris, and was as zealous in his endeavours to reform the Italian theatre there as he had been in his own country. His firſt attempt was in a piece called the "Father of Love," but the bad ſucceſs of this comedy was a ſufficient warning to him to deſiſt from his undertaking. He continued, during the remainder of his engagement, to produce pieces agreeable to the general taſte, and publiſhed twenty-four comedies. At the end of two years he was preparing to return to Italy, when he was ſuddenly urged to become Italian maſter to the princeſſes, aunts to the reigning monarch. During this engagement he loſt his ſight, which he never after completely recovered, and at the end of three years he received a very inadequate recompence for his labour and the time ſpent at court, namely, 100 louis in a gold box, and the grant of a penſion of four thouſand livres per ann. This, with what he was enabled to make by his works, was amply ſufficient for all his wants. When he had attained his 62d year he began to publiſh comedies in the French language, which were well received, and ſome of them became extremely popular. After the death of Lewis XV. Goldoni was appointed Italian teacher to the princeſs Clotilde, the preſent princeſs of Piedmont, and after her marriage, he attended the unfortunate princeſs Elizabeth in the ſame capacity. His laſt work was the "Volponi," written after he had retired from court. It was his misfortune to live to ſee his penſion taken away by the revolution, and, like thouſands in a ſimilar ſituation, he was obliged to paſs his old age in poverty and diſtreſs. He died in the beginning of the year 1793, at a period when the Briſſotines had the ſway in the national councils, and when Goldoni would, for a ſhort time at leaſt, have received every attention that a grateful country could have afforded. As a comic poet, Goldoni is reckoned among the beſt of the age in which he flouriſhed. His works were printed at Leghorn in 1788-91, in 31 vols. 8vo. He has been reckoned the Moliere of Italy, and he is ſtyled by Voltaire "The painter of Nature." "Goldoni," ſays his biographer, "is one of thoſe authors whoſe writings will be reliſhed in the moſt remote countries, and by the lateſt poſterity. His profound knowledge of the human heart, his extenſive deſcription of the vices and virtues of men, in all ages and ſtations, will juſtify my concluding this imperfect eulogy with applying to him the following lines of Horace from his firſt Epiſtle:

> "Æque pauperibus prodeſt, locupletibus æque
> Æque neglectum pueris, ſenibuſque nocebit."

Monthly Magazine. vol. v.

His principal works are comedies in proſe, for declamation, of which the exact number is not known; but they at leaſt amounted to 120 before he left Italy at the deſire of Louis XV. to write for the "Theatre Italien" at Paris, for which theatre he compoſed at leaſt 30.

This fertile, natural, and pleaſing writer, was ambitious at firſt of treating ſerious and tragic ſubjects; but finding, as he tells us himſelf in his life and prefaces, that Metaſtaſio was arrived at as high a point of perfection in his ſerious operas as that ſpecies of drama was capable of, he pointed his thoughts wholly to comedy, which had been long treated in ſuch a buffoon and farcical manner, as to ſtand in great need of reformation.

But though he had determined not to attempt ſerious pieces for muſic, yet Galuppi prevailed upon him, much againſt his inclination, to furniſh him with three ſerious operas for the theatre at Venice; theſe were, Orontes, king of Scythia; Guſtavus Adolphus; and Statira. But though they had great ſucceſs, Goldoni never thought them worthy of publication. He was not more vain of his comic operas. However, he produced at different times and places 40 or 50, which, without his conſent or knowledge, were collected and publiſhed in 6 vols. 12mo.; they are not very eſtimable works, being on the old burletta model, full of buffoonery, and a broad kind of Italian humour, taſted in no other country, though ſuffered for the ſake of the muſic, which is often ingenious, imitative, and ſometimes graceful, but more frequently groteſque.

Goldoni is, perhaps, the only author of comic operas in Italy, who has given them a little common ſenſe, by a natural plot, and natural characters; and his celebrated comic opera of the "Buona Figliuola," ſet by Piccini, and firſt performed in London Dec. 9th, 1766, rendered both the poet and compoſer, whoſe names had ſcarcely penetrated into this country before, dear to every lover of the Italian language and muſic, in the nation. This admirable production, before it was brought hither, had ſaved the *impreſario* of the opera at Rome from ruin, and been performed in the principal cities of Italy. In the year 1760, Piccini, paſſing through Rome, in his way to Milan, was entreated to compoſe a comic opera for the Teatro delle Dame in that city, which had lately been very unfortunate. No *libretto* was ready, and application having been made to the poet Goldoni, at this time in Rome, he furniſhed the muſical drama of "La Bouna Figliuola," from his comedy of "Pamela," in a few days. Several of the original performers were now in London, particularly the firſt buffo, Lovattini, and the ſerious man Savoi, with the *buffo caricato* Morigi. And though females are not allowed to appear on the ſtage at Rome, yet ſignora Guadagni had previouſly performed the part of Cecchina in ſeveral cities of Italy, with great and well-deſerved applauſe before his arrival here.

After the great ſucceſs of the "Buona Figliuola," the public was diſpoſed to hear with partiality any productions by the ſame authors; and when the "Buona Figliuola Maritata," (or Pamela in high life), was brought out, the crowd at the opera-houſe was prodigious; but expectation, as uſual, was ſo unreaſonable as to ſpoil the feaſt; to gratify it was impoſſible. Some aſcribed their diſappointment to the compoſer, ſome to the performers, but none to themſelves. The muſic was excellent, full of invention, fire, and new effects; but ſo difficult, particularly for the orcheſtra, that the performers forgot it was winter. The principal part of the Marcheſa was given to Zamparini, a very pretty woman, but an affected ſinger. Muſic ſo difficult to perform was not eaſy to hear; and this drama was never ſufficiently repeated for the public to be familiarly acquainted with it. They were glad, as well as the performers, to return to the "Buona Figliuola" for their own eaſe and relief from a too ſerious attention.

In France, Goldoni wrote ſeveral very ſucceſsful comedies for declamation in the French language, but we are not acquainted with any dramas which he produced for muſic in that country. Poor Goldoni was in ſuch favour with the royal family of France before the revolution, that he was never allowed to return to his own country; but died at Paris in the year of *terror*, 1793, at the age of 83.

GOLDSBOROUGH, in *Geography*, a poſt town of America, in Hancock county and ſtate of Maine, incorporated in 1789, and containing 379 inhabitants; 47 miles E. of Penobſcot. N. lat. 44° 19′.

GOLDSINNY, in *Ichthyology*, a fiſh diſcovered on the coaſt of Cornwall, in the whole form of the body, lips, teeth, and fins, reſembling the *wraſſe*, which is ſaid never to exceed a palm in length; near the tail is a remarkable black ſpot; the firſt rays of the dorſal fin are tinged with black. See LABRUS *Cornubius*.

GOLDSMITH, OLIVER, in *Biography*, was born in the county of Longford, Ireland, in 1731, though, according to other accounts, this event took place at Elphin, in 1729. He was the ſon of a clergyman, who gave him a literary education, and ſent him early to Dublin college. Being deſigned for the profeſſion of medicine, he was removed to Edinburgh in 1751, where he continued till 1754, when he left that place to avoid a proceſs againſt him for debts incurred, probably to adminiſter to his diſſipation. He was intercepted at Sunderland, and thrown into confinement, from which he was releaſed by the kindneſs of two fellow-collegians. After this, he determined to viſit the continent, embarked for Holland, travelled through Flanders and part of Germany, paſſed ſome time at the univerſities of Straſburg and Louvain; at the latter place he took his degree of bachelor of phyſic, and thence accompanied an Engliſh gentleman to Geneva. Here he engaged himſelf as travelling tutor to a young man who had become poſſeſſed of a large fortune, but whoſe mind was ill adapted to do credit to the gifts of Providence. They diſagreed in the ſouth of France, and Goldſmith was left to contend with the hardſhips of indigence in a foreign country. He returned in 1758, and had in moſt of his peregrinations truſted for his ſupport to his own caſual efforts. His learning enſured him a favourable reception at the monaſteries, and his German flute ſeldom failed to procure him a meal and a night's lodging from the peaſantry, who were delighted with ſtrains which a politer audience would have treated with diſdain. His arrival at London with a few pence in his pocket, was not likely to be the termination of his pecuniary diſtreſſes. He attempted to get into the employ of an apothecary, but his appearance being againſt him, his application was treated with diſdain. He at length was admitted as uſher to Dr. Milner, who kept an academy at Peckham. Here he remained but a ſhort time, and then reſolved to follow the profeſſion of an author in London. He obtained ſome employment in the Monthly Review, and furniſhed papers for the public Ledger. He publiſhed a weekly pamphlet, entitled "The Bee," and "An Enquiry into the ſtate of Polite Learning in Europe." After he had been ſome time exerciſing his pen in obſcurity, he became on a ſudden celebrated as a poet, by the publication of his "Traveller, or a Proſpect of Society." This work had lain by him in MS. ſome years, and it was at the inſtigation of Dr. Johnſon that he prepared it for the preſs. That great critic declared it as his opinion, that there had not been ſo fine a poem ſince the days of Pope. In this deciſion the public concurred, and the author was, almoſt immediately, introduced to the moſt eminent literary characters of the age. In the following year was publiſhed his novel of the "Vicar of Wakefield," which had been ſold to a bookſeller ſome years before, but had been kept back as the work of an unknown writer, and exciting no expectations of ſucceſs. It was, however, received with unbounded applauſe, and has ever ſince borne a diſtinguiſhed rank among ſimilar compoſitions. His next work was a "Hiſtory of England," in a ſeries of letters from a nobleman to his ſon, in two volumes 12mo. a work that ſtill continues to be read with great delight. His poetical fame reached its ſummit in 1770, by the publication of his "Deſerted Village," which was univerſally admired. For this he obtained of his bookſeller 100*l.* a ſum which appeared to the author ſo exorbitantly great, that he refuſed to take it; but the ſale of the work convinced him that he might fairly appropriate the ſum out of the profits. As an author of comedy, he produced in 1768 "The Good-natured Man," which was not very ſucceſsful; and in 1772 another play, entitled "She Stoops to Conquer, or the Miſtakes of a Night." From this Goldſmith cleared a large ſum, and it is ſtill occaſionally repreſented to applauding audiences. Notwithſtanding the ſucceſs of his pieces, by ſome of which it is aſſerted he cleared 1800*l.* in a ſingle year, his circumſtances were never very proſperous, which was partly owing to the liberality of his diſpoſition, and partly to an unfortunate habit which he had contracted of gaming; the arts of which he knew very little of, and conſequently became the prey of thoſe who were baſe enough to take advantage of his ſimplicity. Beſides the works already treated of, Dr. Goldſmith, as he was called, though he had only taken a bachelor's degree, compiled an Engliſh hiſtory in four volumes, and a Roman and Grecian hiſtory in two volumes each; and "A Hiſtory of the Earth and Animated Nature," in eight volumes 8vo. Such was the confidence which he acquired in his ſkill at compilation, that he formed a plan for a much greater work, *viz.* "A Dictionary of Arts and Sciences," but this and other ſchemes which he had planned were cut off by his untimely death. A deſpondence of mind, probably occaſioned by the conſciouſneſs of the bad ſtate of his affairs, had been ſecretly preying upon him, when in March 1774 he was attacked with the ſymptoms of a low fever, under which he ſunk on the 4th of April. He was buried in the Temple churchyard without much attendance, but a monument has ſince been erected to his memory in Weſtminſter abbey, with a Latin inſcription by Dr. Johnſon.

Goldſmith, as a man, was rather admired for his genius, and beloved for his benevolence, than ſolidly eſteemed. The beſt part of his moral character was a warmth of ſenſibility, which made him in all fortunes ready to ſhare his purſe with the indigent, and rendered him in his writings the conſtant advocate of the poor and oppreſſed. The worſt feature was a malignant envy and jealouſy of ſucceſsful rivals, which he ſometimes diſplayed in a manner not leſs ridiculous than offenſive.

As a writer, no one of his time was poſſeſſed of more true humour, or was capable of more poignancy in marking the foibles of individuals. This laſt talent he diſplayed in a very amuſing manner in his poem entitled "Retaliation," written as a retort to the jocular attacks made upon him in a club of which he was a member. His literary fame ſtands higheſt as a poet, in which character a place may be given him perhaps at the head of the minor claſs, the term minor being applied with relation to the quantity, rather than the excellence of compoſition. "It would not be eaſy," ſays his biographer, "to point out in the whole compaſs of Engliſh poetry, pieces that are read with more delight than "The Traveller;" and "The Deſerted Village." The elegance of the verſification, the force and ſplendour yet ſimplicity of the diction; the happy mixture of animated ſentiment with glowing deſcription, are calculated to pleaſe equally the refined and the uncultivated taſte. The moral and philoſophical views of ſociety they exhibit are, indeed, objectionable; yet upon the whole they exert a favourable influence over the heart. In addition to theſe capital works, his pleaſing ballad of "The Hermit," and ſome ſhort humorous and miſcellaneous pieces, complete the catalogue of his performances in verſe. As a proſe writer he deſerves high praiſe for ſtyle, which he adapts with great felicity to his ſubject, and which, whether elevated or plain, is always clear, pure, and unaffected. Life prefixed to his poems. Europ. Mag. Ann. Regis.

GOLDWIN, John, an eccleſiaſtical compoſer, was brought up under Dr. William Child, and, in 1697, ſucceeded him as organiſt at the free chapel of St. George at Windſor. In 1703 he was appointed maſter of the choiriſters there, in both which ſtations he continued to the time of his death in 1719. Dr. Boyce, out of a great number of anthems by this compoſer, ſelected one for four voices, "I have ſet God always before me," which he has inſerted in the ſecond volume of his "Collection of Cathedral Muſic," and well characterized it with reſpect to the modulation, by ſaying that "it is ſingular and agreeable."

GOLDYLOCKS, in *Botany*. See Chrysocoma and Gnaphalium.

GOLEEAH, in *Geography*, a town of Bengal; 18 miles E. of Rangur. N. lat. 22° 28′. E. long. 85° 51′.

GOLETTA, a fortreſs of Africa, ſituated on a canal, in the kingdom of Tunis; 25 miles N. of Tunis.—Alſo, a narrow channel between the lake of Tunis and the ſea, defended on each ſide by a caſtle.

GOLF, or Goff, the name of a diverſion or exerciſe, much uſed in Scotland, and played upon the lawns or links, as they are there called.

It conſiſts of driving a ball with clubs, between two goals or holes, half a mile or a mile aſunder. He who can do this with the feweſt ſtrokes of his club is the conqueror.

GOLFO Triste, in *Geography*, a bay on the coaſt of South America, in the government of Caraccas. N. lat. 10° 30′. W. long. 68° 20′.

GOLGAM, a town of Hindooſtan, in Dowlatabad; 15 miles N. of Beder.

GOLGOM, a town of the iſland of Ceylon; 48 miles N.W. of Candy.

GOLGOTHA. See Calvary.

GOLIATH, in *Scripture Hiſtory*, a famous giant of Gath, who defied the armies of Iſrael, and was ſlain by David. 1 Sam. xvii. 4, &c.

GOLICH, in *Geography*, a town of Ruſſia, in the government of Irkutſch, on the Lena; two miles S. of Orlenga.

GOLINDA, a ſmall iſland near the N. coaſt of Cuba. N. lat. 23° 20′. W. long. 80° 4′.

GOLISANO, a town of Sicily, in the valley of Demona; 9 miles S. of Cefalu.

GOLITZ, a town of Nubia, on the left ſide of the Nile; 45 miles W.N.W. of Dongola.

GOLIUS, James, in *Biography*, was born at the Hague in 1596; but he purſued his ſtudies at Leyden with the moſt unremitting diligence and ardour, and became diſtinguiſhed for his deep knowledge of the learned languages, antiquities, philoſophy, and mathematics. In 1622 he accompanied an embaſſador of the United Provinces to Morocco, where he excited the admiration of the emperor Muley Zeidan, with whom he had frequent interviews. After his return to his native country he ſucceeded to the Arabic profeſſorſhip on the death of Erpenius, under whom he had formerly ſtudied. In 1625 he obtained permiſſion to travel in the Levant, and paſſed more than a year at Aleppo, whence he made various excurſions into Arabia and Meſopotamia. On his return he viſited Conſtantinople, where he obtained very diſtinguiſhed notice from the learned in that capital, by whoſe means he had acceſs to the beſt libraries. During his abſence he was appointed profeſſor of mathematics, and returned to Leyden in 1629, and applied himſelf to the duties of his office. He died in 1667, having occupied with much credit the arduous ſituation of profeſſor for more than forty years, and paſſed through all the academical honours. As an author he publiſhed the "Saracen Hiſtory of Elmacin," which had been begun by Erpenius: alſo a life of the great Tamerlane, written by an eminent Arabian author: "The aſtronomical Elements of Alfergan," with a new verſion and learned commentaries: "An Arabic Lexicon;" a "Perſian Dictionary," which was printed in London. Bayle. Moreri.

Golius, Peter, brother of the preceding, entered when very young among the Carmelites; like his brother he excelled in the knowledge of the Arabic language, and taught it in the ſeminary belonging to his order at Rome, where thoſe monks were educated who were intended to be ſent on miſſions into the Eaſt. Golius was deſtined to this ſervice, and having viſited every part of Syria and Paleſtine, founded a monaſtery of his order on mount Libanus, over which he preſided till he was recalled to Rome. Here he was employed as one of the principal aſſiſtants of Sergius Riſius, archbiſhop of Damaſcus, in preparing his edition of the Arabic bible, which was publiſhed in 1671 by the direction of the college "De Propaganda." After it was completed, Golius was appointed viſitor of the miſſions of the Eaſt Indies. He died in this employment at Surat about the year 1673. He was author of tranſlations into Arabic of Thomas à Kempis' imitation of Jeſus Chriſt: of ſermons on the Evangeliſts: an "Hiſtoric diſcourſe of St. Gregory of Decapolis:" ſeveral ſmall devotional pieces, and a tranſlation from Arabic into Latin of a "Collection of Parables and Proverbs." Moreri.

GOLLI, or Colli, in *Geography*, a town of Africa, near the river Grande, the inhabitants of which trade in ſlaves, ivory, and cotton.

GOLLING, a town of the archbiſhopric of Salzburg, on the Sulza; 14 miles S.S.E. of Salzburg.

GOLLOSING, a town of Bengal; 70 miles W. of Midnapour.

GOLNITZ, a town of Hungary, on a river of the ſame name; 14 miles S.E. of Kapſdorff.

GOLNOW, a town of Anterior Pomerania, formerly Hanſeatic, ſituated on the Ihna; 12 miles N. of Stargard. N. lat. 53° 37′. E. long. 24° 57′.

GOLO, a river of Corſica, which riſes nearly in the centre of the iſland, and purſuing a N.E. courſe, runs into the ſea; 12 miles S.S.E. of Baſtia. It gives name to one of the two departments into which the iſland is divided; the other being Liamone. Golo comprehends the northern diviſion of Corſica, in N. lat. 42° 30′, and containing 165 ſquare leagues, and 103,466 inhabitants, is ſubdivided into three circles, *viz.* Baſtia, whoſe inhabitants are 47,842; Calvi, having 20,282 inhabitants; and Corte containing 35,342 inhabitants. There are ſeveral lofty mountains near the centre of a chain that traverſes the iſland longitudinally. The moſt conſiderable lakes are Ino and Creno, the former of which is of unknown depth. The ſoil is tolerably fertile, yielding barley, millet, olives, cheſnuts, wine, fruits, &c. On the hills are foreſts and excellent paſtures. See Corsica.

GOLOBGUNGE, a town of Bengal; 10 miles E. of Silhet.

GOLPHINGTON, the chief town of Waſhington county and ſtate of Georgia, in America, ſituated near the head of Ogeechee river, about 26 miles E.S.E. of Oconee town.

GOLPS, in *Heraldry*, are roundles, or torteaux, of a purple colour.

GOLTBERGENSIS Terra, in the *Materia Medica*, a whitiſh earth, uſed in the ſhops of Germany and Italy as an aſtringent, a cordial, and a ſudorific, but little known among the Engliſh apothecaries. It is dug in many parts of Germany, as Goldberg and Strigaw, and Lignitz in Sileſia; but particularly at this time in the neighbourhood of Haſſelt, in the biſhopric of Liege, in the circle of Weſtphalia. It is taken up there in conſiderable quantities, and uſually is ſealed with the impreſſion of an eagle, and with its old name Goltbergenſis terra under it. It was imagined to contain ſome particles of ſilver, and thence to derive ſome of its virtues: on this account Montanus called it *axungia lunæ;* but experience ſhews that it doth not contain a particle of that metal. It is a denſe compact earth of a dull greyiſh white, ſoft and friable, and adheres firmly to the tongue; and makes no efferveſcence with acids.

GOLTIAVINA, in *Geography*, a town of Ruſſia, in the government of Tobolſk; 188 miles E. of Eniſeik. N. lat. 58° 20′. E. long. 98° 14′.

GOLTPACH, a town of Pruſſia, in the palatinate of Culm; 8 miles N.E. of Thorn.

GOLTVA, a town of Ruſſia, in the government of Kiev; 112 miles S.E. of Kiev. N. lat. 49° 15′. E. long. 33° 14′.

GOLTZEN, a town of Lower Luſatia; 10 miles W. of Lubben. N. lat. 51° 58′. E. long. 13° 30′.

GOLTZIUS, Hubert, in *Biography*, a painter, who was born at Venlo in 1520, and ſtudied under Lambert Lombard. Becoming enamoured of the antique by having copied ſeveral works of that claſs, he reſolved to cultivate his taſte by viſiting the more important Greek works preſerved at Rome; and therefore travelled to that city, where he reſided ſome time, and thence drew an ample ſtock of materials for his future progreſs in the art he profeſſed.

He lived principally at Antwerp, where he painted the hiſtory of Jaſon; but as he was engaged in a variety of ſtudies, his pictures are rare. Among other things he inveſtigated coins and medals, and publiſhed a collection of them with critical annotations. He died at the age of 63.

Goltzius, Henry, an artiſt of conſiderable talent, who practiſed both painting and engraving. As a painter, he drew his reſources from the ſtudy of the antique, of Raphael, Polidoro, and Michael Angelo; the laſt of whom appears to have been his favoured Apollo in the art, but whoſe faults he exaggerated in an outrageous manner, ſeldom attaining any of his beauties. Hence his ſtyle of deſign is inflated and caricature; and his expreſſions participate of the ſame taſte; but his ſenſe of hue in colour is rich, vigorous, and tranſparent. He died in 1617, aged 59.

GOLUB, in *Geography*, a town of Pruſſia, in the territory of Culm; 24 miles S.E. of Culm.

GOLUBENSKA, a town of Ruſſia, in the country of the Coſſacks, on the Don; 200 miles E.N.E. of Azoph.

GOMAHNY, a town of Hindooſtan, in the circar of Mohurgunge; 45 miles N.W. of Harriopour.—Alſo, a town of Bengal; 8 miles S.S.E. of Goragot.

GOMAR, Francis, in *Biography*, celebrated as the great opponent of Arminius, and from whom the Calviniſtic party in Holland received the name of "Gomariſts," was born about the year 1563 at Bruges. His parents had been brought up in the Roman Catholic religion, but having embraced the Proteſtant doctrines, they retired into the palatinate in 1578, for the ſake of profeſſing their principles in peace and ſecurity. Their ſon Francis was ſent to Straſburg for his education, and purſued his ſtudies there under the celebrated John Sturm, after which he went to Newſtadt, whither the profeſſors of Heidelberg had been obliged to retire by the elector Lewis, becauſe they were the opponents of the Lutheran faith. In 1582 he took a journey to England, and attended the divinity lectures at the univerſities of Oxford and Cambridge. He was admitted to the degree of B.D. in the year 1584. By great aſſiduity he became very deeply learned in the Greek and Hebrew languages, and in 1587 he ſettled with a Dutch congregation at Frankfort, and continued to diſcharge his miniſterial functions, in that connection, until the year 1593, when his flock was entirely diſperſed by perſecution. In the following year he was invited to accept the theological profeſſorſhip at Leyden, and having taken his degree of D.D. he entered upon the duties of his new ſtation. In 1603 Arminius was appointed his colleague, and openly and zealouſly oppoſed the gloomy doctrines maintained by John Calvin, and made many converts in the univerſity. This rouſed the attention of Gomar, who declared himſelf his opponent, diſputed with him in the ſchools of Leyden, and publiſhed treatiſes to excite the orthodox to make a firm ſtand againſt his doctrines, which he repreſented to be profane and impious; he went much farther, and endeavoured to provoke againſt him the indignation of the States of Holland, before whom the two combatants diſputed twice in the year 1608. On one occaſion, when Barnevelt exclaimed that he was grateful to God that their controverſies did not affect the fundamental articles of the Chriſtian religion, Gomar proteſted "that he could not appear before the throne of God with Arminius's errors," thus vainly ſetting limits to the mercy of the moſt high and moſt merciful God. In 1611, ſeeing that his opponents increaſed in numbers and in ſtrength, Gomar reſigned his office, and retired to Middleburg. After this, he accepted the profeſſorſhip of divinity, firſt at the academy of Saumur, and then at the univerſity of Groningen, and at the latter place he was employed as the Hebrew profeſſor, in addition to that of theology. He was preſent at the ſynod of Dort, and took an active part in procuring the infamous decrees by which the Arminians were condemned and proſcribed as corrupters of the true faith, and enemies to their country. He died at Groningen in 1641, leaving a diſtinguiſhed character for ſound learning, particularly in the Oriental languages, but it cannot, and it ought not to be concealed, that he diſgraced the character of a Chriſtian miniſter by his bigotry and intolerance. As an author, he publiſhed many treatiſes, but chiefly on controverſial ſubjects, which were collected and printed at Amſterdam in the year 1645. He was alſo concerned in reviſing the tranſlation of the Old Teſtament, printed at Leyden with notes in the year 1637. Moreri. Bayle.

GOMASTAHPOUR, in *Geography*, a town of Bengal, 42 miles N.W. of Nattore.

GOMAUN, or Kemaoon, the name of mountains of Aſia, called alſo thoſe of Sewalic; an extenſive ridge, which ſeems to form the exterior barrier of the Thibetian Alps in Sirinagur, &c.

GOMBAULD, John Ogier De, in *Biography*, a French poet of the ſeventeenth century, was the younger ſon of a gentleman of the Proteſtant religion, to which he adhered. He was educated at Bourdeaux, and came to Paris about the time of the death of Henry IV., and frequented the court of Mary de Medicis. Of her he obtained a penſion of 1200 crowns, which was but ill-paid, and which was ſoon reduced nominally to one-third of that ſum, ſo that, notwithſtanding his high patrons, he paſſed much of his life in a ſtate little above indigence. He was elected one of the firſt members of the French Academy, and was ſo extremely zealous for its great object, the purity of the language, that he once propoſed to the academicians that they ſhould bind themſelves by oath to uſe no words but ſuch as were approved by the majority of the ſociety. He lived to a good old age, and died in 1666. He was author of many tragedies, tragi-comedies, paſtorals and romances, ſonnets, epigrams, &c. He alſo engaged in theological controverſy, and wrote "Treatiſes and Letters concerning Religion," in favour of the Proteſtants. Gombauld was very ready at repartee, and his wit did not leave him even in old age, for his lateſt publication was a collection of epigrams. Moreri. Bayle.

GOMBERT, Nicolas, a diſciple of Juſquin, who publiſhed two books of motets for many voices in 1552. He ſet to muſic a Latin epitaph on his maſter Juſquin;

quin; and at this time compoſers being ſcarce, he gained ſome reputation among thoſe of Flanders, with very little genius. For after performing the tedious taſk of ſcoring the muſic of the nænia on Juſquin, we found its chief merit to conſiſt in imitations of his admirable maſter. This compoſition was in the third eccleſiaſtical mode of E, with a minor ſecond, as well as third; which M. Blainville ſome years ago wiſhed to paſs on the public for a third or new key, different from the major and minor, which compriſe all ſecular muſic at preſent. And it is extraordinary, that this pretenſion ſhould have had any abettors in a Roman Catholic country, where old compoſitions in this mode are daily performed in cathedrals and collegiate churches. However, it was a matter of wonder and debate, during ſome time, in France. See Mercure de France, 1751, and Dict. de Muſ. par Rouſſeau, art. *Mode*.

GOMBERVILLE, MARIN LE ROI, *Sieur de*, a man of letters, was born at Chevreuſe, in the dioceſe of Paris. He became diſtinguiſhed at the age of fourteen by a collection of quatrains in honour of old age. In 1635 he was ſo much diſtinguiſhed for a literary reputation, that he was of the number aſſembled by cardinal Richlieu for the purpoſe of founding the French academy. He had publiſhed romances and works of a light nature, of which he afterwards ſeemed to be aſhamed, for at the age of forty-five he formed the reſolution of conſecrating his pen to religion. He even adopted a penitentiary courſe of life, and is mentioned by ſome of his contemporaries as having joined the Chriſtian virtues to thoſe of morality. He died in 1674, leaving behind him many works, of which perhaps the beſt is a "Diſcours ſur les Vertus et les Vices de l'Hiſtoire et de la Maniere de bien écrire." This is deemed a ſenſible and very judicious performance. Moreri.

GOMBEY, in *Geography*, a town of Africa, in Botonga, on the Zambeze. S. lat. 18°. E. long. 36° 3'.

GOMBEZCALA, a town of Perſia, in the province of Farſiſtan; 100 miles N.N.W. of Schiras.

GOMBIN, GAMBIN, or *Gabin*, a town of Poland, in the duchy of Warſaw, ſituated on the river Bſura; 34 miles N.N.E. of Rawa.

GOMBRON. See GAMBRON.

GOMER, in *Scripture Hiſtory*, the ſon of Japheth (Gen. x. 2.) and, according to Joſephus, father to the people of Galatia. The ancient inhabitants of that country were called Gomares before the Galatians ſeized poſſeſſion of it. The Chaldee places Gomer in Africa; Bochart in Phrygia, becauſe Phrygia, in Greek, has the ſame ſignification (a coal) as Gomer, in Hebrew and Syriac. Others are of opinion that the ancient Cimbri, or Cimmerians, ſprung from Gomer, and probably from them the Welſh, called Cymri. It is not improbable, that Gomer, or the Gomerites, his deſcendants, peopled likewiſe Germany and Gaul; the name German not differing much from Gomerim. Cluvier (Germ. Antiq. l. i. c. 5. 6.) conjecturing that the ancient Celtica comprehended Illyria, Germany, Gaul, Spain, and the Britiſh iſles, as all theſe people anciently ſpoke the ſame language, farther ſuppoſes, that Gomer, or his family, peopled the countries in Aſia, between the Paropamiſus and mount Imaus, and between the confluence of the Oxus and Oby; whence theſe people are called Gomares by Ptolemy (l. vi. c. 17.) and Mela (l. i. c. 2.).

GOMER, or *Omer*, an Hebrew meaſure. See CORUS.

GOMERA, or VELEZ DE PEGNON, in *Geography*, a caſtle of Africa, in the country of Fez, built on a rock near the coaſt of the Mediterranean. Before this fortreſs there was anciently a city, called "Bedis," ſuppoſed to have been founded by the Carthaginians. The Arabs called it Belis and Velis, whence Veles. Theſe two places, ſurrounded by mountains and foreſts, were ſupported by the building of ſhips for fiſhing and piracy, before they were taken by the Spaniards.—Alſo, a river of Fez, which runs into the ſtraits of Gibraltar, near the above-mentioned fortreſs.

GOMERA, or *Gomara*, one of the Canary iſlands, about 20 miles long and 10 broad, having a capital of the ſame name, ſituated on the eaſt coaſt, with a good harbour. The iſland is fertile and well cultivated, and produces ſugar-canes and vines in abundance, as well as ſilk, together with ſufficient corn for the ſupply of the inhabitants, who amount to about 7000; 18 miles S.W. of Teneriffe. N. lat. 28° 6'. W. long. 17° 8'.

GOMETRA, one of the weſtern iſlands of Scotland. This is a ſmall iſland at the weſt end of Ulva, tolerably fertile, but without wood.

GOMEZ DE CIVIDAD REAL, ALVAREZ, in *Biography*, a modern Latin poet, was born in 1488 at Guadalaxara in Spain. He was page of honour to archduke Charles, afterwards emperor. As an author, which entitles him to a place in this work, he poſſeſſed a great facility in writing Latin verſe, which is ſeen by his "Thalia Chriſtiana," or the triumph of Jeſus Chriſt, in twenty-five books: "Muſa Paulina," or the epiſtles of St. Paul, in elegiac verſe: the Proverbs of Solomon, and other works of a ſimilar kind. His work on the order of the Golden Fleece, entitled "De Principis Burgundi Militia quam Velleris aurei vocant," is reckoned his maſter-piece. The ſubject which he choſe in this inſtance was more favourable to poetry than the others. Moreri.

GOMEZ DE CASTRO, ALVAREZ, a native of St. Eulalia, near Toledo, was educated at Alcala, where he obtained a high character for diligence and real learning. He was patronized by Philip II., who engaged him to prepare an edition of the works of Iſidore, which death prevented him from completing. He was author of many works; but the chief, and that which is moſt eſteemed, is a "Life of Cardinal Ximenes," inſerted in a collection of the writers on Spaniſh hiſtory. Gomez died in 1580, at the age of 65. Moreri.

GOMEZ, MAGDALEN-ANGELICA POISSON, born at Paris in 1684, was the daughter of Paul Poiſſon, an actor. Her fertile pen produced a great variety of romances and other works of the entertaining kind. The principal are, "Les Journées Amuſantes," in eight volumes. "Anecdotes Perſanes," two vols. "Hiſt. Secrete de la Conquête de Grenade." "Hiſtoire du Comte d'Oxford avec celle d'Euſtache de St. Pierre." "Les cent Nouvelles." She died in 1770, at the age of 86.

GOMEZ, SEBASTIANO, a Mulatto ſlave of the Spaniſh painter Murillio, who employed his leiſure hours in painting, and obtained conſiderable ſucceſs. The city of Seville is, or was, adorned with many of his works: the moſt conſpicuous among them were a "Madonna with the Infant," in the portico of Los. Mercenarios Deſcalxos, and the "Flagellation of Chriſt," at the Capuchins. It is not known at what period he died; but he is ſaid to have ſurvived his maſter, whoſe deceaſe happened in the year 1685.

GOMGAH, in *Geography*, a town of Hindooſtan, in the circar of Surgooja; 22 miles S.W. of Surgooja.

GOMI, a town of the province of Guriel, on the Black ſea.

GOMMERN, a town of Saxony, on the Elbe; 8 miles E. of Magdeburg.

GOMNIALPAR, a town of Hindooſtan, in the circar of Guntoor; 15 miles E. of Innaconda.

GOMORA, a ſmall iſland in the Eaſt Indian ſea, near the weſt coaſt of Oby. S. lat. 1° 52′. E. long. 128°.

GOMORRHA, in *Ancient Geography*, a town of Paleſtine, and one of the principal cities of the Pentapolis, conſumed by fire from heaven. It was probably the moſt northern of the five cities. Gen. xix. 24.

GOMOZIA, or GOMEZIA, in *Botany*. See NERTERIA.

GOMPHIA, from γομφος, *a nail* or *knob*, alluding to the form of the receptacle of the fruit. Schreb. 291. Willd. Sp. Pl. v. 2. 569. Mart. Mill. Dict. v. 2. (Jabotapita; Plum. Gen. 41. t. 32. Ochna; Gærtn. t. 70. Juſſ. 282.) Claſs and order, *Decandria Monogynia*. Nat. Ord. *Magnoliæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, ſharpiſh, ribbed, coloured, deciduous leaves, two of which have a membranous margin at each ſide, one on one ſide only, and two are deſtitute of any. *Cor.* Petals five, ſpreading, longer than the calyx, rather unequal; the claws are ſhorter than the calyx, each gradually widening into a roundiſh, flat, entire border. *Stam.* Filaments ten, very ſhort, thick and angular; anthers erect, ſhorter than the calyx, ſquare, tapering upwards, burſting at the top, on the outſide, by two pores. *Piſt.* Germen placed on a ſhort fleſhy angular receptacle, with five angles and five diviſions; ſtyle longer than the ſtamens, marked with five furrows; ſtigma acute. *Peric.* Drupas from one to five, moſt generally two, ovate, obliquely attenuated at the baſe, ſomewhat compreſſed, obtuſe, erect, ſtanding on a very large globoſe receptacle, which is undivided, if the berry be ſolitary, lobed if there be more, one lobe being appropriated to each berry. *Seeds* ſolitary, ovate.

Eſſ. Ch. Calyx five-leaved, inferior. Petals five, with claws rather unequal. Anthers nearly ſeſſile, ſquare, opening by two pores. Drupas ſtanding on a rounded fleſhy receptacle.

Vahl and Swartz deſcribe five ſpecies, all trees, natives of tropical climates. The chief and original one is G. *Jabotapita*, (Ochna Jabotapita; Linn. Sp. Pl. 732. Jabotapita pyramidato flore luteo, fructu rubro; Plum. Ic. 147. t. 153.) This is a native of South America, flowering in December and January. The *wood* is ſoft and tough. *Leaves* ſimple, as in the whole genus, alternate, ſtalked, ovate, acute, ſerrated. *Flowers* in terminal cluſters, yellow, fragrant, compared by Marcgrave to thoſe of a Wall-flower in figure, or rather colour, but he ſays their ſcent is ſweeter. The *fruit* and its receptacle are black, juicy, aſtringent.

This genus is certainly very nearly related to *Ochna*, both in habit and character.

GOMPHIASIS, from γομφος, *a nail*, a diſorder of the teeth, in which they become looſe and painful. The connection of the derivative with the Greek is imputable to the circumſtance of the teeth being fixed in their ſockets, like nails in a piece of wood.

GOMPHOCARPUS, in *Botany*, from γομφος, any thing ſwelling upwards from a narrow baſe, as a nail, wedge, or club, and καρπος, *fruit*, alluding to the tumid follicles. Brown Aſclepiad. (from the Wernerian Society's Tranſactions) 26. The genus is confounded by Linnæus under his *Aſclepias*. Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ. *Aſclepiadeæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, ſmall, in five acute, permanent ſegments. *Cor.* of one petal, regular, in five deep, reflexed ſegments, deciduous. Nectary of five hooded leaves, ſimple within, furniſhed with a tooth at each ſide, placed on the top of the united filaments. *Stam.* Filaments five, cohering; anthers of two cells, terminated by a membrane, and producing two compreſſed maſſes of pollen, which attach themſelves by a taper point to the ſtigma, and remain pendulous there. *Piſt.* Germens two, ſuperior, ovate, ſtyles two, very ſhort, ſtanding cloſe together; ſtigma common to the two, dilated, horizontal, flat, with five angles to receive the maſſes of pollen. *Peric.* Follicles two, inflated, ovate, pointed, clothed with ſoft ſpines. Receptacles membranous, longitudinal, linear, at length ſeparate. *Seeds* numerous, imbricated, pendulous, crowned with ſilky down.

Eſſ. Ch. Corolla in five deep reflexed ſegments. Nectary of five hooded leaves, ſimple, with a ſingle tooth on each ſide, crowning the filaments. Anthers terminated by a membrane. Stigma depreſſed, pointleſs. Follicles inflated, prickly. Seeds hairy.

This genus is ſeparated from *Aſclepias* by Mr. Brown, (whoſe eſſay on the whole order, and whoſe diſcovery of the mode in which the pollen is projected by the anthers upon the ſtigma, do him the higheſt honour,) on account of the inflated prickly fruit, and the ſingular horns which in *Aſclepias* grow out from the bottom of the nectaries. It conſiſts of *Aſclepias arboreſcens*, Linn. Mant. 216; *fruticoſa*, Linn. Sp. Pl. 315; and *ſetoſa*, Vahl. Symb. v. 1. t. 8; and, as Mr. Brown ſuſpects, of *criſpa*, Linn. Mant. 215. Suppl. 170. A. *pubeſcens*, Linn. Mant. 215, is, as he juſtly obſerves, on the authority of the late excellent Mr. Dryander, borrowed from the Linnæan herbarium, the ſame plant as *arboreſcens*, with a ſynonym from Plukenet (t. 139. f. 1.) and Moriſon, which is preſumed to be *criſpa*.

GOMPHOLOLIUM, ſo named by the writer of the preſent article, from γομφος, *a wedge*, *club*, or any thing ſwelling upwards from a narrow baſe, and λοβος, *a pod*, or *legume*, expreſſive of its tumid fruit. Sm. Tr. of Linn. Soc. v. 4. 220. Ann. of Bot. v. 1. 505.—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coriaceous, ſhort, bell-ſhaped, in five deep, oblong, pointed, unequal ſegments. *Cor.* papilionaceous. Standard very large, inverſely heart-ſhaped, carinated at the back, recurved, with a ſhort claw. Wings ſhorter than the ſtandard, parallel, horizontal, with a prominent lobe on one ſide near the baſe. Keel the length of the wings, of two half-ovate, tumid, clawed petals, with a reverſed tooth at the upper edge of each. *Stam.* Filaments ten, concealed in the keel, awl-ſhaped, diſtinct, aſcending, rather unequal in length; anthers vertical, roundiſh, two-lobed. *Piſt.* Germen ſtalked, oblong, ſomewhat cylindrical; ſtyle awl-ſhaped, aſcending, as long as the ſtamens; ſtigma ſimple, acute. *Peric.* Legume on a ſtalk, nearly globular, inflated, of one cell, crowned with the ſtyle. *Seeds* ſeveral, roundiſh, ranged along the upper ſuture on ſhort ſtalks.

Eſſ. Ch. Calyx bell-ſhaped, ſimple, in five deep ſegments. Corolla papilionaceous. Stigma ſimple. Legume inflated, globoſe, of one cell, with many ſeeds.

Five ſpecies of this genus are defined in the Tranſactions of the Linnæan Society, v. 9. 249, G. *grandiflorum*, Exot. Bot. t. 5:—*latifolium*, (*fimbriatum*; Exot. Bot. t. 58:) *ſcabrum*, a ſpecies communicated by Mr. Menzies: *minus*, very near the laſt, except in the acute recurved points of the leaves: and *pinnatum*, a ſmall ſpecies from Port Jackſon, remarkable for its pinnate leaves, and zig-zag herbaceous ſtem. Probably the ſubſequent volume of Mr. Brown's Prodromus will add more to this number.

The habit of *Gompholobium* is marked by the compound (ternate or pinnate) leaves, and a certain aſpect of rigidity and ſmoothneſs. The ſtipulas are not intrafoliaceous as in

Pultenæa, but ſtand on each ſide of the baſe of the common footſtalk, being a pair of acute flat cloſe-preſſed leaves, extremely minute, and often altogether wanting. The flowers are yellow, generally numerous, large and handſome; in G. *ſcabrum* they are purple when dried, but this is ſuſpected to be an alteration of their original hue, and they are judged, from the analogy of *Davieſia*, to be yellow, with crimſon keel and wings, when freſh.

All the ſpecies, as far as hitherto known, are natives of New Holland. S.

GOMPHOSIS, in *Anatomy*, from γομφος, *a nail*, denotes the manner in which the fangs of the teeth are fixed in their ſockets.

GOMPHRENA, in *Botany*, a name adopted by Linnæus from Dalechamp, and which is perverted from the *Gromphena* of Pliny. Linnæus made it claſſical by an alluſion to γομφος, *a nail*, *wedge*, or *club*, which can but obſcurely apply to the round head of flowers. See Gromphena.—Linn. Gen. 123. Schreb. 172. Willd. Sp. Pl. v. 1. 1321. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 1. 318. Juſſ. 88. Lamarck. Illuſtr. t. 180. Gærtn. t. 128. (Amaranthoides; Tournef. t. 429.)—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Holeraceæ*, Linn. *Amaranthi*, Juſſ.

Gen. Ch. reformed. *Cal.* Perianth inferior, coloured, membranous, permanent, double; the outer of two large, compreſſed, keeled leaves, cohering by their inner margins, and one ſmaller; inner in five deep, awl-ſhaped, upright, downy ſegments. *Cor.* of one petal, tubular, cylindrical, the length of the inner calyx; its margin equally five-cleft, ſpreading. *Stam.* Filaments five, very ſhort, inſerted into the orifice of the corolla, betwixt its ſegments; anthers erect, roundiſh, cloſing the mouth of the corolla. *Piſt.* Germen ovate, pointed, ſuperior; ſtyles ſhort, cohering at their bottom part; ſtigmas ſimple, obtuſe, ſcarcely reaching to the ſtamens. *Peric.* Capſule roundiſh, membranous, of one cell, burſting all round. *Seed* ſolitary, large, roundiſh, with an oblique point.

Eſſ. Ch. Calyx coloured, the outer of three unequal leaves; inner in five deep ſegments. Corolla cylindrical, five-toothed, bearing the ſtamens at its orifice. Capſule burſting all round. Seed ſolitary.

The ſpecies of *Gomphrena* come under the denomination of Everlaſtings, or Amaranths, on account of the permanent nature of their calyx when dried, which retains its original colour and ſplendour.

G. *globoſa*, Globe Amaranth, a native of India, is commonly raiſed on a hot-bed, and planted out in our borders, like other tropical annuals. It is alſo frequently kept in pots to decorate the ſtove or green-houſe. The original crimſon ſort is much more handſome than the paler variegated variety.

G. *perennis*, figured in Dill. Hort. Elth. t. 20, a native of Buenos Ayres, is ſcarcely cultivated but in curious gardens, having ſmall heads of yellowiſh flowers of no remarkable beauty.

There are eight ſpecies beſides in Willdenow, of which the *arboreſcens*, Linn. Suppl. 173, is by far the moſt remarkable. This was not ſent to Linnæus by Mutis from New Granada, as erroneouſly aſſerted by the younger Linnæus in the *Supplementum*, but by Vandelli, who received it from Brazil, and who has deſcribed it under the name of *Bragantia*, in his Faſc. Plant. p. 6. The *ſtem* is woody, round, leafy, clothed with rigid, prominent, brown hairs, as are alſo the *leaves*, which are oppoſite, obovate, obtuſe, entire, about three inches long, and half as broad. *Heads* terminal, ſolitary, the ſize of an African Marigold or *Tagetes*, pale red or whitiſh, compoſed of innumerable flowers, the ſegments of whoſe calyxes are above an inch long, linear, acute and chaffy, clothed in their lower part with long denſe ſilky hairs. We know of no figure of this fine plant.

Mr. Brown, Prodr. Fl. Nov. Holl. v. 1. 416, adds four new ſpecies to *Gomphrena*, while he removes from it the *braſilienſis* and *vermicularis*, which, with two new ones from the tropical part of New Holland, he forms into a new genus, *Philoxerus*. He conſiders what we term corolla in *Gomphrena*, as the tube of the united filaments

Gomphrena, in *Gardening*, contains a plant of the flowery annual kind, of which the ſpecies cultivated is, the annual globe amaranth (G. globoſa.)

It is a fine flowering plant, the heads of which at their firſt appearance are globular, but as they increaſe in ſize become oval, and, according to Martyn, the flowering heads are extremely beautiful, and, if gathered before they are too far advanced, retain their beauty ſeveral years.

There are varieties with fine bright purple heads, with white or ſilvery heads, which never alter from ſeeds, with mixed colours, with purple and with white heads, which two laſt are much ſmaller and rounder than the others; the plants alſo grow much larger and ſpread more into branches, and are later before they flower; theſe are called batchelor's buttons in America.

Method of Culture.—It may be increaſed by ſowing the ſeeds annually, in pots of light freſh mould, in the early ſpring months, and plunging them in the bark hot-bed. When the plants are up, they ſhould be watered often with care; and, after they have attained ſome growth, be removed with balls about their roots into other pots, and replunged in the hot-bed. When they have had ſome growth in this ſituation, they ſhould be removed into a deep frame, being placed in a freſh hot-bed, to bring them up tall and handſome. Afterwards they ſhould be often refreſhed with water, and have air admitted freely as the ſummer advances, till they are capable of bearing it without injury; when about Auguſt they may be ſet out during the daytime, being protected in the night, and from wet weather. At this period they ſhould be watered three or four times a week at leaſt, in a rather ſparing manner.

They afford a good effect when ſet out in the principal ſituations about the houſe, in aſſemblage with other plants of the potted kinds.

GOMRAPENDY, in *Geography*, a town of Hindooſtan, in the Carnatic; 25 miles N. of Madras.

GOMS, one of the ſeven independent dixains or commonwealths of the Upper Vallais, in Switzerland; called *dixain*, becauſe the Upper and Lower Vallais comprehend 10 diſtricts, each being a dixain or tenth of the whole. Goms is ſituated at the foot of mount Grimſel, and extends along the bank of the Rhône; and is ſo called from a town, 33 miles E. of Sion. See Vallais.

GOMUT, a river of Bengal, which runs into the Magna, near Chandpour.

Gomut *Peperee*, a town of Hindooſtan, in Dowlatabad; ſix miles N. of Amednagur.

GOMUTTRA Selagitta, in *Natural Hiſtory*, the name given by the Indians to a kind of foſſil, found in great plenty on the mount Vindy in the Eaſt Indies, in places, as they obſerve, where the cows frequently urine. It is a bituminous ſubſtance, and after calcination the reſiduum is given in caſes of internal ulcers and in gonorrhœas. The Indians ſuppoſed it formed by the drying up of the cow's urine.

GONAGRA, compoſed of γονυ, *knee*, and αγρα, *captura*, *ſeizing*, in *Medicine*, the gout in the knee. See Gout.

GONAMBOUCH, in *Ornithology.* See Emberiza *Griſea.*

GONANPILLY, in *Geography*, a town of Hindooſtan, in the circar of Ellore; 18 miles N.E. of Ellore.

GONAPI, one of the ſmaller Banda iſlands, in the centre of which is a volcano. The only inhabitants are wild hogs, cows and ſerpents. S. lat. 4° 10′. E. long. 130° 34′.

GONARCHA, a term in the ancient dialling. Mr. Perrault, in his notes on Vitruvius, lib. ix. cap. 9. takes the gonarcha to have been a dial drawn on divers ſurfaces or planes; ſome of which being horizontal, others vertical, oblique, &c. formed divers angles.

Whence the appellation, from γονυ, *knee*, or γωνια, *angle.*

GONARY, in *Geography*, a town of Hindooſtan, in the Myſore; 12 miles S. of Rydroog.

GONAVE, La, an iſland ſituated on the weſt ſide of St. Domingo, about 14½ leagues in length, and about three in breadth. This is called Grand Gonave by way of diſtinction from Petit Gonave, another ſmall iſland about two miles in each direction, ſeparated from the S.E. corner of the former, by a channel three miles wide. Gonave is 13½ leagues W. by N.W. from Port au Prince. N. lat. 18° 51′. W. long. 73° 40′. See St. Domingo.

GONAVES, a ſea-port in the above-mentioned iſland, at the head of a bay of its own name, on the N. ſide of a bay of Leogane. The harbour is excellent; the town has a medicinal ſpring, and in 1772 both were erected with lodging-houſes for the accommodation of thoſe who reſort to it, and an hoſpital for ſoldiers and ſailors. It lies on the great road from Port de Paix to St. Mark, 16 leagues S.E. of the former. N. lat. 19° 22′. W. long. 73° 20′.

GONCANAMA, a town of S. America, in the audience of Quito; 20 miles S.W. of Loxa.

GONCELIN, a town of France, in the department of the Iſere, and chief place of a canton, in the diſtrict of Grenoble; 13 miles N.N.W. of Grenoble. The place contains 1558, and the canton 10,259 inhabitants, on a territory of 197½ kiliometres, in 14 communes.

GONDAR, the metropolis of Abyſſinia, is ſituated upon a hill, elevated 8440 feet above the ocean, and conſiſts of about 10,000 families in times of peace. The houſes are chiefly conſtructed with clay, and the roofs are thatched in a conical form, which is the mode of building within the tropical rains. On the weſt end of the town is the king's houſe, formerly a ſtructure of conſiderable importance; it was a ſquare edifice, flanked with ſquare towers; formerly four ſtories high, and the top of it afforded a magnificent view of the whole country S. of the lake Tzana. Although the greateſt part has been burnt at different times, there is ample lodging in the two loweſt floors of it; the audience chambers being above 120 feet long. Annexed to this ruined palace are apartments, conſtructed by ſucceeding kings, alſo of clay, according to the faſhion of their own country; for the palace itſelf, ſays Bruce (Travels, vol. iii.) was built by maſons from India in the time of Facilidas, and by ſuch Abyſſinians as had been inſtructed in architecture by the Jeſuits, without embracing their religion, and afterwards remained in the country, unconnected with the expulſion of the Portugueſe, during this prince's reign. The palace and its contiguous buildings are ſurrounded by a ſtone wall, 30 feet high, with battlements upon the outer wall, and a parapet roof between the outer and inner, by which you may paſs along the whole and have a view of the ſtreet. There never appear to have been any embraſures for cannon; the four ſides of this wall are above 1½ Engliſh mile in length. The mountain, on which the town is ſituated, is encompaſſed on every ſide by a deep valley, which has three outlets; the one to the ſouth, to Dembea, Maitſhaw, and the Agows, the ſecond to the N.W., towards Sennaar over the high mountain Debra Tzai, or the mountain of the Sun, at the foot of which Koſcam, the palace of the Iteghé, is ſituated, as are alſo the low countries of Walkayt and Waldubba; the third is to the N. to Woggora, over the high mountain Lamalmon, and ſo on through Tigré to the Red ſea. The river Kahha, coming from the mountain of the Sun, runs through the valley, and covers all the ſouth of the town; the Angrab, falling from Woggora, ſurrounds it on the N.N.E.: theſe rivers join at the bottom of the hill, about a quarter of a mile S. of the town. On an eminence oppoſite to Gondar, on the other ſide of the river, is a large town of Mahometans, conſiſting of about 1000 houſes. They are all active and laborious, and are employed in taking care of the baggage and field-equipage of the king and nobility, when they take the field and return from it; but they never fight on either ſide. N. lat. 12° 34′ 30″. E. long. 37° 53′.

GONDEBAUD, in *Biography*, third king of the Burgundians, celebrated as a legiſlator among the barbarians over whom he reigned as ſovereign. He obtained the crown in 491, and almoſt immediately, under pretence of aſſiſting Odoacer againſt Theodoric, entered Italy, carrying fire and ſword through Æmilia and Liguria, and made a great number of captives, many of whom he liberated without ranſom, at the requeſt of Epiphanius biſhop of Pavia. He aſſembled, in 499, a council at Lyons, in order to effect a reconciliation between the Catholics and Arians. He was himſelf an Arian, from habit and education; but he was unable to effect ſo laudable a purpoſe. About this time he was attacked and defeated by Clovis king of the Franks; who made the Burgundian monarch his tributary. Clovis returned to his own country, and Gondebaud revenged himſelf upon his brother Godegeſil, who had joined Clovis, ſurpriſed him, and put him to death. From this period he reigned in peace over his people, whom he rendered flouriſhing by the arts of civilization, and by a regular ſyſtem of laws. Theſe, ſays the hiſtorian, were in general founded on equity, and diſplay much ſagacity in preventing all cauſes of diſpute; nevertheleſs, they enjoin the barbariſm of judicial combats, which the legiſlator juſtified as an inference from the admitted doctrine of the interference of a particular providence in human affairs. The Burgundian code, called "La loi Gombrette," has been publiſhed in ſeveral collections of ancient laws. This prince died in 516, leaving behind him, as memorials, letters upon theological ſubjects to Avitus, biſhop of Vienne. Univer. Hiſt.

GONDEGAMA, or Gondlacomma, in *Geography*, a river of Hindooſtan, which forms the nominal boundary of the Carnatic, and diſcharges itſelf into the ſea at Medipelly. Combam, or Commum, is near its ſource. It is ſometimes called Gilligama, and Gunta-camma.

GONDICOTTA, a town of Hindooſtan, in Marawar; 33 miles N. of Trumian.

GONDOLA, a little flat boat, very long and narrow, chiefly uſed at Venice to row on the canals.

The word is Italian, *gondola.* Du Cange derives it from the vulgar Greek κουνδελας, *a bark*, or *little ſhip*; Lancelot deduces it from κονδυ, a term in Athenæus for a ſort of vaſe.

The middle-ſized gondolas are upwards of thirty feet long, and four broad; they always terminate at each end in a very ſharp point, which is raiſed perpendicularly to the full height of a man.

The addreſs of the Venetian gondoliers, in paſſing along their narrow canals, is very remarkable; there are uſually two to each gondola, and they row by puſhing before them. The fore-man reſts his oar on the left ſide of the gondola: the hind-man is placed on the ſtern, that he may ſee the head over the tilt or covering of the gondola, and reſts his oar, which is very long, on the right ſide of the gondola.

GONDOLA is alſo the name of a paſſage-boat of ſix or eight oars, uſed in other parts of the coaſt of Italy.

GONDOLA-*ſhell*, in *Natural Hiſtory*, a name given by authors to a peculiar kind of *concha globoſa*, ſuppoſed, in ſome degree, to repreſent the ſhape of a Venetian boat. It is of the genus of the *dolium*, and there are ſeven ſpecies of it. See DOLIUM and CONCHOLOGY.

GONDOMAR, in *Geography*, a town of Spain, in Galicia; 6 miles E. of Bayona.

GONDRECOURT, a town of France, in the department of the Meuſe, and chief place of a canton, in the diſtrict of Commercy. The place contains 1113, and the canton 8973 inhabitants, on a territory of 340 kiliometres, in 24 communes.

GONDUFEE, a town of Africa, in the kingdom of Kong; 100 miles S E. of Kong.

GONDWARRAH, a town of Bengal; 15 miles S.S.W. of Purneah.

GONESSE, a town of France, in the department of the Seine and Oiſe, and chief place of a canton, in the diſtrict of Pontoiſe, nine miles N. of Paris. The place contains 2400, and the canton 14,811 inhabitants, on a territory of 182½ kiliometres, in 22 communes.

GONET, JOHN BAPTIST, in *Biography*, was born at Beziers in the year 1616. He embraced the eccleſiaſtical life when he was young, and was admitted to the degree of doctor of divinity by the univerſity of Bourdeaux in the year 1640. He was at the ſame time elected to the profeſſorſhip of theology in that univerſity, an office which he held with great dignity till the year 1671, when he was appointed provincial among the Dominican friars. In 1675 he reſumed his labours as profeſſor, which he continued about two years, and then retired to his native place, where he died in 1681. He was author of a ſyſtem of divinity, entitled "Clypæus Theologiæ Thomiſticæ, contra novos ejus impugnatores," firſt publiſhed at Bourdeaux in 1666, in eighteen volumes 12mo., but it was afterwards enlarged, and printed in five volumes folio. He was likewiſe author of a "Manuale Thomiſtarum, ſeu brevis Theologiæ Curſus," which has paſſed through different editions, of which the beſt was publiſhed at Lyons in 1681: and "Diſſertatio Theologica de Probabilitate." Moreri.

GONFALON, or GONFANON, a kind of round tent, borne as a canopy, at the head of the proceſſions of the principal churches at Rome, in caſe of rain; its verge or banner ſerving for a ſhelter, where there is not a great deal of attendance.

GONG, a Chineſe metalline, muſical inſtrument of percuſſion, in the form of a flat baſon, with a ridge round it, and beaten by a mallet covered with ſeveral folds of woollen cloth. It is carried on a pole by two men, and beaten by the hindmoſt. In the march of an army, it is uſed as a military inſtrument to regulate the ſteps of the ſoldiers; when ſtruck with great force, it is ſufficiently loud to be heard at a mile's diſtance; but ſo confuſed is the ſound, that no diſtinct tone can be aſcertained. Yet by reiterated gentle ſtrokes on the ſame part of the bottom of the baſon a muſical tone may be produced; but different parts of the circle produce tones of different gravity and acuteneſs

It is uſed in proceſſions, and at court on days of ceremony and feſtivals, in concert with other inſtruments, as a double drum. On the water, in veſſels that are rowed, this inſtrument regulates the ſtrokes of the oars.

It is formed of braſs or bronze, and called Lu by the Chineſe, who, from hearing it only on great occaſions, regard it with reverence.

GONGA, in *Geography*, a town of European Turkey, in Romania, near the ſea of Marmora; 36 miles N.E. of Gallipoli.

GONGA, or *Bain Gonga*, a river of Hindooſtan, which falls into the Godavery about 90 miles from the ſea. See BAIN *Gonga*, and GODAVERY.

GONGACA, a town of Bengal; 30 miles S.W. of Calcutta.

GONGADEE, a town of Bengal; 50 miles S.W. of Rogonautpour.

GONGOLARA, in *Botany*, a name by which Imperatus has called a very beautiful ſea plant, known among botanical writers by the name of *fucus ericæ foliis*, or *erica marina*, the ſea heath.

GONGONG, is an inſtrument uſed by the Hottentots, and all the negroes on the weſtern coaſt of Africa. Of this kind there are two ſorts, the large gongong and the ſmall. In the ſupplement to the firſt edition of the French Encyclopédie, a deſcription of this inſtrument has been attempted, that ſeems totally unintelligible.

"The ſmall gongon (ſay the editors) is an iron or holly bow, of which the ſtring is the ſinew of a ſheep dried in the ſun, or a bowel ſtring; at the extremity of the bow is placed, on one ſide, the pipe of a ſplit quill, in the hollow of which the ſtring of the bow is lodged. The performer holds this quill in his mouth when he is playing, and the different tones of the gongon proceed from the different modulations of his breath.

"The great gongon only differs from the ſmall by the ſhell of a cocoa-nut, of which the upper part has been cut off, and the ſtring of the bow, before its tenſion, paſſed through it on each ſide. In touching the inſtrument the cocoa-ſhell is moved to and from the quill according to the tone which is to be produced."

We hope our readers will comprehend this deſcription, by which we frankly own ourſelves not to be much enlightened; nor can we well conceive how the motion of the ſplit quill, or the ſection of the cocoa-nut, can produce different tones. Nothing that anſwers to this deſcription is to be found on the plate referred to (fig. 3. Pl. II.) but in Pl. III. fig. 9. Muſ. Inſt. there is, we think, a very unſatisfactory repreſentation of it. And in the rude ſtate in which the European arts in general have been found in ſuch parts of Africa as have already been explored, we have little reaſon to lament our ignorance of the conſtruction and uſe of the gongong.

GONGOO, in *Geography*, an iſland in the Neel Abud or Guin river of Africa, in its courſe between Caſhna or Kaſſina, and Mekzara. N. lat. 16. E. long. 11°.

GONGOOPOUR, a town of Hindooſtan, in Oude, 12 miles S. of Kairabad.

GONGORA, LEWIS, in *Biography*, a celebrated Spaniſh poet, was born at Cordova in 1562. He ſtudied at Salamanca, and being brought up to the church, was made chaplain to the king, from whom he received conſiderable eccleſiaſtical preferment. He died at Cordova, of the cathedral of which he was prebend. His reputation is built on a volume of poems, under the title of "Obras de Dom. Louis de Gongora-y-Argore," 4to. The poems conſiſt of a variety of compoſitions, chiefly of the ſhorter kind, eſpecially lyrical, in which ſtyle he ſo much excelled, as to be termed by his countrymen "the prince of lyric poets." Gongora poſſeſſes, in the eſtimation of his countrymen, a very high rank among the Spaniſh poets for an artificial elevation of language, and uncommon turn of thought, which were formerly the characteriſtics of the poetry of that nation. So much, indeed, did he ſurpaſs in theſe qualities, that he had many cenſurers in his own country, though he alſo met with as many warm defenders. He is ſaid to have enriched his native language by the introduction of many Latin words happily employed. Moreri.

GONGRONA, in *Surgery*, a hard tumour; but eſpecially a bronchocele, or ſwelling of the thyroid gland. The word is ſaid to be derived from γογγρος, a round tubercle on the trunk of a tree.

GONHARY, in *Geography*, a town of Hindooſtan, in Oude; 40 miles W. of Lucknow.

GONIA, a town of Aſiatic Turkey, in Natolia; 16 miles W. of Aphiom-Karahiſar.

GONJAH, or KONG, ſuppoſed to be the *Conche* of D'Anville, and the *Gonge* of Deliſle, a kingdom of Africa, ſituated to the N. of Guinea, between the meridian of Greenwich, and 5° W. long., and between the 10th and 12th degrees of N. lat. It is about 870 miles weſtward from Caſhna or Kaſſina, and between 530 and 600 miles from the Gold Coaſt. Some ſay, there is no communication between this coaſt and the country of Gonjah; the king of Aſſentoi, who poſſeſſes the intervening ſpace, prohibiting his inland neighbours from paſſing through his country. Others report, that other ſtates (*e. g.* the Fantees, and their confederates) lie between Aſſentoi and the ſea; and that the Aſſentois have often unſucceſsfully attempted to open a communication with the coaſt.—Alſo, the name of a town, which is the capital of the kingdom of Gonjah or Kong. N. lat. 11° 30′. W. long. 3° 30′.—Alſo, the name of part of a chain of mountains, extending from almoſt the mouth of the river Gambia, in the Atlantic, to Nigritia, towards Abyſſinia.

GONIAH, a decayed town and large caſtle of Aſiatic Turkey, belonging to the province of Guriel, at the mouth of a river which runs into the Black ſea. It is garriſoned by a few Janiſſaries, and inhabited chiefly by ſeamen; 80 miles E.N.E. of Trebiſond. N. lat. 41° 25′. E. long. 41° 10′.

GONJENPILLY, a town of Hindooſtan, in the Carnatic; 18 miles N.E. of Nellore.

GONIOCARPUS, in *Botany*, ſo called from γωνια, *an angle*, and καρπος, *fruit*, expreſſive of one of its eſſential characters. The name, originally contrived by Thunberg, was *Gonocarpus*, which being incorrectly conſtructed, and too near *Conocarpus*, was judiciouſly changed by Mr. Konig. Schreber, Willdenow, and others, have made it *Gonatocarpus*, for want of attending to its meaning and application, which has no reference to γονυ, γονατος, *a knee*, but to the very peculiar angles of the fruit.—Konig in Ann. of Bot. v. 1. 546. t. 12. f. 5, 6. (Gonocarpus; Thunb. Nov. Gen. 55. Fl. Jap. 5. Murr. in Linn. Syſt. Veg. ed. 14. 164. Juſſ. 442. Lamarck. Illuſtr. t. 73. Gonatocarpus; Schreb. 86. Willd. Sp. Pl. v. 1. 690. Mart. Mill. Dict. v. 2.)—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Onagræ*, or *Onagrariæ*, Juſſ. Konig.

Gen. Ch. *Cal.* Perianth ſuperior, in four deep, acute, equal, upright ſegments. *Cor.* Petals four, equal, oblong, concave, inſerted into the rim of the calyx, and twice as long as its teeth. *Stam.* Filaments four or eight, very ſhort, inſerted into the calyx, oppoſite to the petals if four, to the petals and calyx-teeth if eight; anthers oblong, large, ſhorter than the corolla. *Piſt.* Germen inferior, turbinate, with eight furrows and as many angles, crowned with the permanent calyx; ſtyle extremely ſhort; ſtigmas four, obtuſe, downy.

Eſſ. Ch. Calyx ſuperior, in four deep equal ſegments. Petals four. Drupa dry, with eight angles. Nut ſolitary, of one cell.

Three ſpecies of this inconſpicuous though curious genus are at preſent known.

1. G. *micranthus.* Thunb. Jap. 69. t. 15.—Leaves ovate, obtuſely crenate, ſmooth, as well as the ſtem.—Gathered by Thunberg in Japan. *Root* fibrous, annual. *Stems* three or four inches high, aſcending, quadrangular, ſmooth, leafy, ſimple below, panicled above. *Leaves* oppoſite, on ſhort ſtalks, ovate, rather acute, half an inch long, bluntly crenate and cartilaginous in the margin, ſmooth on both ſides, minutely dotted, furniſhed with a rib, but no veins; the upper ones gradually ſmaller and more entire. *Stipulas* none. *Flowers* very ſmall, purpliſh, drooping, in ſeveral ſlender, lax, upright ſpikes, forming a ſort of panicle. The *petals* as well as *calyx* are ſufficiently evident in Thunberg's own ſpecimens before us. The *fruit* is no bigger than the ſmalleſt pin's head, and the petals ſcarcely longer.

2. G. *rotundifolius.*—Leaves rounded, ſomewhat heart-ſhaped, obtuſely crenate, ſmooth. Angles of the ſtem rough. Spikes in a compound panicle.—Gathered near Port Jackſon, New South Wales, by John White, M. D.—We are by no means certain that this is more than a variety of the former, but its different country, much more rounded *leaves*, heart-ſhaped at the baſe, and the briſtly angles of the *ſtem*, induce us to propoſe it as a ſpecies. Poſſibly the panicled *ſpikes* may be owing to the greater luxuriance of the ſpecimens. The *fructification* appears preciſely like that of the firſt ſpecies.

3. G. *ſcaber.* Konig Ann. of Bot. v. 1. 547. t. 12. f. 6.—Leaves elliptic-lanceolate, ſharply ſerrated, briſtly as well as the ſtem.—Gathered by Mr. David Nelſon, in cultivated ground in the iſland of China, near Macao. This appears to differ from the two former very materially, being all over rough, with depreſſed briſtles, and having longer and narrower ſharply ſerrated *leaves.* The *flowers*, moreover, have eight ſtamens, and the angles of the *fruit* are wavy or criſped, not ſmooth and even.

We have a plant gathered by Dr. White, near Port Jackſon, which ſeems to anſwer in every point to Mr. Konig's deſcription and figure of the laſt, except that its petals have a briſtly keel, and the ſtigmas are ſingularly branched and plumoſe, making a large tuft in the centre of each flower after the petals are fallen. Perhaps Mr. Konig's ſpecimens had loſt all their ſtigmas. We remark, however, a further difference in the fruit, whoſe alternate angles are leſs diſtinct, or rather more criſped and interrupted than the reſt. Not having examined authentic ſpecimens of *G. ſcaber*, we muſt leave this matter in doubt.—Poſſibly this may be *G. tetragynus.* Billard. Nov. Holl. t. 53.

GONIOMETER, an inſtrument uſed for the purpoſe of meaſuring ſolid angles (particularly of cryſtals), or the inclination which one plane ſurface makes with another. The ſmall goniometers, as uſually ſold at the ſhops, are of a conſtruction ſo ſimple, as to require but little deſcription. They generally conſiſt of a ſmall pair of compaſſes or nippers, deſtined to receive the angle of the cryſtal; and the legs of theſe being continued in the oppoſite direction, beyond the angular point or joint, the angle is meaſured by applying them to a protractor or ſemicircular ſcale of degrees.

But notwithſtanding much ingenuity has been beſtowed on inſtruments conſtructed on this principle, none of them have been found nearly accurate enough for the purpoſes for which they are required, many intereſting queſtions in the modern ſcience of cryſtallography requiring a much more exact determination of the angle than can poſſibly be obtained by inſtruments of this conſtruction.

We are indebted to Dr. Wollaſton for having removed all theſe difficulties, by the invention of an inſtrument which accompliſhes all that the moſt ſcrupulous naturaliſt can poſſibly deſire. The principle of this invention is entirely optical, and (*Plate* XIX. *Miſcellany*, *fig.* 2.) repreſents the inſtrument as made and ſold by Mr. Carey, in the Strand; but the reader, when acquainted with the nature of it, will readily ſee that any perſon poſſeſſed of a graduated inſtrument, ſuch as a theodolite, tranſit, &c. may, without great difficulty, apply it to the meaſurement of angles, though in a much leſs commodious manner than on an inſtrument made expreſsly for the purpoſe.

Dr. Wollaſton's method conſiſts in employing a ray of light reflected from the ſurface, inſtead of the ſurface itſelf; and thus, for a radius of 1-50th of an inch, we may ſubſtitute either the diſtance of the eye from the cryſtal, which would naturally be twelve or fifteen inches, or for greater accuracy we may, by a ſecond mode, ſubſtitute the diſtance of objects ſeen at a hundred yards or more from us. The inſtrument deſcribed by Dr. Wollaſton, in the Tranſactions for 1809, conſiſts of a circle, *fig.* 3, graduated on its edge, and mounted on an horizontal axle ſupported by an upright pillar. This axle, being perforated, admits the paſſage of a ſmaller axle through it, to which any cryſtal of moderate ſize may be attached by a piece of wax, with its edge, or interſection of the ſurfaces, horizontal and parallel to the axis of motion. This poſition of the cryſtal is firſt adjuſted, ſo that by turning the ſmaller axle, each of the two ſurfaces, whoſe inclination is to be meaſured, will reflect the ſame light to the eye. The circle is then ſet to zero, or 180 , by an index attached to the pillar that ſupports it.

The ſmall axle is then turned till the further ſurface reflects the light of the candle, or other definite object, to the eye; and laſtly, (the eye being kept ſteadily in the ſame place,) the circle is turned by its larger axle, till the ſecond ſurface reflects the ſame light. This ſecond ſurface is thus aſcertained to be in the ſame poſition as the former ſurface had been: the angle through which the circle has moved, is, in fact, the ſupplement to the inclination of the ſurfaces; but as the graduations on its margin are numbered accordingly in the inverted order, the angle is correctly ſhewn by the index, without requiring any computation.

It may be here obſerved, that it is by no means neceſſary to have a clean uniform fracture for this application of the inſtrument to the ſtructure of laminated ſubſtances; for ſince all thoſe ſmall portions of a ſhattered ſurface that are parallel to one another, (though not in the ſame plane,) gliſten at once with the ſame light, the angle of an irregular ſurface may be determined nearly as well as when the reflecting ſurfaces are actually in the ſame plane. In this method of taking the meaſure of an angle, when the eye and candle are only ten or twelve inches diſtant, a ſmall error may ariſe from parallax, if the interſection of the planes or edge of the cryſtal be not accurately in a line with the axis of motion. But ſuch an error may be rendered inſenſible, even in that mode of uſing the inſtrument, by due care in placing the cryſtal; and when the ſurfaces are ſufficiently ſmooth to reflect a diſtinct image of objects, all errors from the ſame ſource may be entirely obviated by another mode of uſing it.

For this purpoſe, if the eye be brought within an inch of the reflecting ſurface, the reflected image of ſome diſtant chimney may be ſeen inverted beneath its true place, and, by turning the ſmall axis, may be brought to correſpond apparently with the bottom of the houſe, or ſome other diſtant horizontal line. In this poſition the ſurface accurately biſects the angle which the height of that houſe ſubtends at the eye, or rather at the reflecting ſurface: then, by turning the whole circle and cryſtal together, the other ſurface, however ſmall, may be brought exactly into the ſame poſition; and the angle of the ſurfaces may thus be meaſured, with a degree of preciſion that has not hitherto been expected in goniometry.

The accuracy, indeed, of this inſtrument is ſuch, that a circle of moderate dimenſions, with a vernier adapted to it, will probably afford corrections to many former obſervations. Dr. Wollaſton has remarked one inſtance of a miſtake that prevails, reſpecting the common carbonate of lime, which he mentions, becauſe this ſubſtance is very likely to be employed as a teſt of the correctneſs of ſuch a goniometer, by any one who is not convinced of its accuracy, from a diſtinct conception of the principles of its conſtruction.

The inclination of the ſurfaces of a primitive cryſtal of carbonate of lime, is ſtated with great appearance of preciſion to be 104 28′ 40′: a reſult deduced from the ſuppoſed poſition of its axis, at an angle of 45°, with each of the ſurfaces, and from other ſeducing circumſtances of apparent harmony by ſimple ratios.

But however ſtrong the preſumption might be, that this angle, which by meaſurement approached to 45′, is actually ſo, it muſt nevertheleſs be, in fact, about 45° 20′; for the inclination of the ſurfaces to each other is found to be very nearly, if not accurately, 105″, as it was formerly determined to be by Huygens; and ſince the meaſure of the ſuperficial angle, given by ſir Iſaac Newton, correſponds with this determination of Huygens, his evidence may be conſidered as a further confirmation of the ſame reſult; for it may be preſumed, that he would not adopt the meaſures of others without a careful examination.

Explanation of the Figure.

a b, Is the principal circle of the goniometer, graduated on its edge.

c c, The axle of the circle.

d, A milled head, by which the circle is turned.

e e, The ſmall axle for turning the cryſtal, without moving the circle.

f, A milled head on the ſmall axle.

g, A braſs plate ſupported by the pillar, and graduated as a vernier to every five minutes.

h, The extremity of a ſmall ſpring, by which the circle is ſtopped at 180 , without the trouble of reading off.

i i and *k k*, Are two centres of motion, the one horizontal, the other vertical, for adjuſting the poſition of a cryſtal; one turned by the handle *l*, the other by the milled head *m*.

The cryſtal being attached to a ſcrew head at the point *n*, in the centre of all the motions, with one of its ſurfaces as nearly parallel as may be to the milled head *m*, is next rendered truly parallel to the axis, by turning the handle *l* till the reflected image of a horizontal line is ſeen to be truly horizontal. By means of the milled head *f*, the ſecond ſurface is then brought into the poſition of the firſt, and if the reflected image from this ſurface is found not to be horizontal, it is rendered ſo by turning the milled head *m*, and ſince this motion is parallel to the firſt ſurface, it does not derange the preceding adjuſtment.

GONIOMETRICAL Lines, derived from γωνια, *angle*, and μετρω, *I meaſure*, in *Geometry*, lines uſed for meaſuring or determining the quantity of angles. Such are ſines, tangents, ſecants, verſed ſines, &c.

We have a paper by Mr. Jones, in the Philoſophical Tranſactions, containing a commodious diſpoſition of equations for exhibiting the relations of goniometrical lines, from whence a multitude of curious theorems may be derived. See Phil. Tranſ. N°. 483. ſect. 26.

GONIUM, in *Zoology*, a genus of Vermes, characterized only by their very ſimple, flat, and angular form, and being inviſible to the naked eye. The ſpecies at preſent known are few, amounting to no more than five in number; and for the exiſtence of theſe we rely chiefly on the microſcopical reſearches of Muller and Schranck, the former of whom deſcribes four of theſe minute creatures with great accuracy in his "Zoologia Danica." They are moſtly inhabitants of freſh or pure water, though ſome of them occur in ſtagnant water or in dunghills.

Species.

Polysphærium. Orbicular, pellucid, with innumerable ſpherical molecules. Schranck.

Found in ſtagnant water; the colour greeniſh-yellow, and general appearance that of a thin membrane filled with innumerable lucid globules. Very common in the month of July.

Pectorale. Quadrangular, pellucid, with ſixteen ſpherical molecules. Müll. Goeze, &c.

The molecules are oval and nearly of an equal ſize, their colour greeniſh, pellucid, and diſpoſed in a quadrangular manner within the membrane, like diamonds in a ring; or rather, as Müller compares them, to the jewels in the breaſtplate of the high prieſt among the Jews, and reflecting light on both ſides. Its progreſs is by an advancement alternately towards the right and left, at which time all the molecules are in motion, and aſſume their oval form, theſe molecules being round when the animal is in a quieſcent ſtate.

Truncatum. Angles obtuſe; poſterior part arched. Müll.

This occurs in freſh or pure water, and is rarely met with; its ſize is rather conſiderable; the fore-part is a ſtraight line, the ſides forming therewith obtuſe angles, the extremity of the ſides being united by a curved line; the internal organs, perceptible to the eye by the aſſiſtance of the microſcope, conſiſt of a number of molecules of a dark green colour, and two veſicles of peculiar brightneſs in the middle. Its motion is languid.

Lunatum. Rectangular, the poſterior part arched. Müll. Gmel. *G. Rectangulum*, Adams.

The projection at the baſe of the body in this ſpecies is placed in a right angle; the inteſtines green, with the larger veſicle tranſparent.

Pulvinatum. Quadrangular, opaque, with four cylindrical protuberances. Müller.

This ſpecies, according to Müller, appears under a ſlight magnifier like a quadrangular membrane, plain on both ſides, but, when a deeper lens is applied, reſembles the figure of a bolſter, formed of three or four cylindrical pillows, flattened or ſunk in various places: this was the appearance it aſſumed when firſt examined; ſome days after all the ſides were plain without convexity and decuſſated, or divided into little ſquares by the interſection of ſtraight lines. It is found in puddles under dunghills.

GONKEER, in *Geography*, a town of Chineſe Tartary. N. lat. 44° 50'. E. long. 117° 51'.

GONKOFEN, or Gankofen, a town of Bavaria; 14 miles E. of Landſhut.

GONNA, a town of Hindooſtan, in Lahore; 12 miles W. of Nugoreote.

GONNI, or Gonno, in *Ancient Geography*, a town of Greece, in the Perrhæbia, ſituated near Pateus, towards the ſtrait where the Olympus and Oſſa approached each other.

GONNOCONDYLUM, a town of Greece, in Macedonia, in the Perrhæbia.

GONOESSA, a town of Greece, in the Peloponneſus. In the time of Pauſanias it belonged to the Sicyonians.

GONOLOBUS, in *Botany*, from γωνια, *an angle*, and λοβος, *a pod*, alluding to the angles or ribs of the fruit. Michaux Boreali-Amer. v. 1. 119. Brown Aſclep. 24.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ. *Aſclepiadeæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, acute, ſpreading ſegments, permanent. *Cor.* of one petal, wheel-ſhaped, in five deep ſpreading ſegments. Nectary like a ſhield, crowning the ſtamens, lobed. *Stam.* Filaments five, thickiſh, united into a ſhort tube; anthers burſting tranſverſely, terminated by a membrane, their maſſes of pollen attached to the outer extremity, with reſpect to the cell, and covered by the ſtigma. *Piſt.* Germens two, ovate-oblong; ſtyles two, very ſhort, cloſe together; ſtigma common to both, flattiſh and depreſſed, with five angles. *Peric.* Pouches inflated, more or leſs angular or ribbed. *Seeds* numerous, imbricated, oblong, crowned with down.

Eſſ. Ch. Corolla wheel-ſhaped, in five deep ſegments. Nectary a lobed ſhield-like crown. Anthers burſting tranſverſely, terminated by a membrane. Stigma five-angled, depreſſed. Pouches inflated, ribbed. Seeds with a hairy crown.

This appears to be a numerous genus, properly ſeparated from *Cynanchum*, and conſiſting of climbing ſhrubs, with oppoſite broadiſh leaves, and flowers growing in umbels between the inſertion of the foot-ſtalks. They are natives of America, chiefly within the tropics. Examples of it are *Cynanchum maritimum*, Linn. Mant. 54. Jacq. Amer. 83. t. 56, a hairy plant, with dark-purple bloſſoms: *ſuberoſum*, Linn. Sp. Pl. 310, figured in Dill. Hort. Elth. t. 229. f. 296, likewiſe a downy ſpecies, with purpliſh-green flowers; and *criſpiflorum*, Ait. Hort. Kew. v. 1. 302. Plum. Ic. t. 216. f. 1: as well as many others preſumed to have the ſame generic characters, but which, according to Mr. Brown, require to be thoroughly examined, as does the whole genus.—Michaux enumerates three ſpecies, natives of the warmer parts of North America, and which he calls G. *macrophyllus*, *hirſutus*, and *lævis*.

GONON Besar, in *Geography*, a mountain on the E. ſide of the iſland of Java, famous for the quantity of pepper which its trees produce.

GONONG, or Ganapez, one of the group of Aſiatic iſles, called *Banda*, in which there is a remarkable volcano.

GONOR, a town of Hindooſtan, in the circar of Gohud.

GONORHYNCHUS, in *Ichthyology*, a ſpecies of *Cyprinus*, which ſee.

GONORRHŒA denotes, in *Surgery*, a diſeaſe in which a kind of matter, which is either actually pus, or a fluid of very ſimilar qualities, is diſcharged from the urethra of the male ſubject, and from the ſurfaces of the labia, nymphæ, clitoris, and vagina of the female, attended with more or leſs heat, pain, and difficulty in making water. The diſcharge is infectious, and capable of communicating the complaint from one perſon to another, whenever it comes into contact with any of thoſe ſurfaces, which are ſuſceptible of contamination by it, and which, we believe, muſt be ſuch as are naturally deſtined to ſecrete mucus. On the foregoing account, the diſorder is almoſt always caught, or communicated, in the venereal connection, when ſome of the diſcharge of the diſeaſed perſon is applied to the parts, which are liable to be affected in the healthy one. However, a gonorrhœa may be produced in any manner, which brings the infectious diſcharge into contact with the mouth of the urethra, the ſurfaces of the labia, &c. In the article OPHTHALMY, we ſhall have occaſion to notice a particular inflammation of the eyes, attended with a copious diſcharge of matter from beneath the eye-lids, which is repreſented, by ſurgical writers, as originating from the inadvertent application of gonorrhœal matter to the eye-lids, the inner ſurfaces of which are well known to be mucous ones.

The Hunterian doctrines go ſo far as to aſſert, on the authority of experiments, that the poiſon of the lues venerea, and that of gonorrhœa, are in fact the ſame, though uſually productive of oppoſite effects, by reaſon of the parts affected in a chancre, and thoſe concerned in gonorrhœa having quite different ſtructures. Theſe things, if true, tend to prove, that the matter of a clap may, under certain circumſtances, impart the venereal diſeaſe to the conſtitution. However, it ſhould be underſtood, that the ſtatement juſt now made can only refer to the gonorrhœa virulenta; for it is certain, that a ſimple diſcharge from the urethra, and a ſcalding ſenſation in making water, which would conſtitute a gonorrhœa, may be the conſequence of any thing which produces mere irritation in the paſſage without the poſſibility of the venereal or common gonorrhœal virus being at all concerned. Thus, a man may have a ſtricture, and begin the employment of bougies for its cure; their irritation may bring on a ſoreneſs in the urethra, and excite a diſcharge. Here we have an inſtance of the complaint ariſing from the operation of no virus whatever; but altogether from the unequivocal, mechanical, irritation of the bougies. Doubtleſs, alſo, there are ſometimes diſcharges both from the male and female parts of generation, which, when applied to other perſons, are capable of bringing on certain kinds of gonorrhœa by the entire effect of their irritation. So were a man, with a gonorrhœa, excited by the irritation of bougies to have connection with a woman, there is no doubt that the latter would be very likely to become troubled with a diſcharge and ſcalding in making water, merely in conſequence of the application of ſome of the matter from the male urethra to the ſurfaces of the labiæ, nymphæ, &c.

The arguments which have been adduced to ſhew that the poiſon of one form of gonorrhœa, and that of the venereal diſeaſe are the ſame, will more properly come under conſideration hereafter. In the meanwhile, it is our part to enter a little more particularly into the hiſtory of gonorrhœa.

The etymological meaning of *gonorrhœa* is a running of the ſemen, the term being derived from γονη, ſignifying the ſeminal fluid, and ρεω, *to flow*. The ancients are ſaid to have entertained the very erroneous notion that the diſeaſe conſiſted of an oozing of the ſemen in a morbid and altered ſtate. As it is long ſince ſo abſurd a ſuppoſition has had any partiſans, a refutation becomes ſuperfluous, and every one now knows, that in the preſent, as in many other examples, truth and etymology are not coupled together. Dr. Swediaur, who has found fault with the term *gonorrhœa*, as conveying an untrue idea, has not been happy in a ſubſtitute. He remarks, that if a Greek name is to be retained, he would call the complaint *blennorrhagia*, from βλεννα, *mucus*, and ρεω, *to flow*. Now this laſt expreſſion is objectionable, on the identical principle which makes Dr. Swediaur wiſh for the relinquiſhment of gonorrhœa; for it is generally thought by all the moſt eminent modern ſurgeons, that the diſcharge is pus, and not mucus. Beſides, we do not ſee much utility in abandoning the ancient appellation. The knowledge of ſurgery is now ſo highly cultivated, that there is not the leaſt danger of any man imbibing an abſurd opinion reſpecting this common complaint, from the etymological import of its name. Every juvenile apprentice knows that a clap is a running of matter from the urethra. Few common practitioners trouble themſelves about Greek derivations; and where is the object of changing the name of one diſeaſe, while many hundred other ſurgical terms ſtand in equal, and often greater, need of alteration?

The firſt perceptible ſymptom of a gonorrhœa is generally a kind of itching about the orifice of the urethra, attended with a ſlight ſwelling of its edges, and ſometimes extending over the whole of the glans penis. Very ſhortly afterwards the running commences, and the itching ſenſation changes into pain, which is ſeverely felt at the time of making water. In ſome few inſtances, no conſiderable pain is experienced, till a long while after the acceſs of the diſcharge and other ſymptoms. It is ſaid that there are certain caſes which are attended with no pain whatſoever, while other inſtances occur, in which patients ſuffer ſeverely, even before the diſcharge makes its appearance.

When the inflammatory ſymptoms have come on, the penis ſeems ſwollen, and as if it were in a ſtate of half-erection. The glans appears red, ſmooth, and enlarged, with a kind of tranſparency about it. Sometimes it is affected with a ſlight excoriation, which makes it exceedingly tender, and is the ſource of ſome trivial quantity of matter. The canal of the urethra becomes narrower than natural, if we may form a judgment from the diminution which takes place in the ſtream of urine. Indeed, very frequently, this fluid can only be diſcharged in a broken ſcattered current, or by drops. We have often ſeen ſevere retentions of urine attendant on the inflammatory ſtage of a gonorrhœa.

Small tumours may frequently be noticed along the inferior ſurface of the penis, in the courſe of the urethra. Theſe ſwellings have been conſidered as the mucous gland of that canal in a ſwollen ſtate. Sometimes they acquire a very large ſize, and ultimately ſuppurate and form abſceſſes, which, in ſome inſtances, burſt externally, while, in others, they break into the urethra itſelf. In the latter event, the ſwelling all on a ſudden ſubſides, as ſoon as the contained matter has eſcaped. Sometimes, after a certain interval, the tumour is ſeen to re-appear, which circumſtance is ſaid to be owing to a premature cloſure of the opening. Abſceſſes of the preceding kind are often met with in the ſituation of Cowper's glands. Here they alſo ſometimes burſt outwardly, ſometimes inwardly, ſometimes in both ways in the ſame patient. In this laſt caſe a new paſſage is made for the urine, termed a fiſtula in perinæo. See FISTULA.

A painful ſenſation is frequently felt by the patient along the lower ſurface of the penis, extending as far as the anus, and depending on the inflamed ſtate of the urethra. In moſt caſes the erections are frequent, and generally productive of infinite pain, particularly when a ſoreneſs exiſts along the track of the urethra towards the anus, or when the complaint is complicated with chordee. See CHORDEE.

The viſcid tranſparent fluid which is naturally ſecreted by the glands of the urethra changes into a whitiſh aqueous liquor, and the ſecretion which takes place from the lining of this canal, and is intended for its lubrication, alſo becomes leſs tranſparent. At length both theſe fluids, becoming thicker and thicker, gradually aſſume more and more the qualities of pus. The diſcharge often undergoes an alteration in its colour and conſiſtence, a circumſtance which Mr. Hunter imputed to the diſpoſition of the parts by which the matter is formed. Sometimes it is white, ſometimes yellow, ſometimes of a greeniſh colour. Such varieties depend upon the diminution, or increaſe of the inflammation, and not upon the poiſonous quality of the matter; for the ſame appearances happen whenever the parts are irritated in a certain degree by any cauſe whatſoever, as ſeveral facts confirm. Dr. Swediaur injected into his urethra ſome cauſtic volatile alkali mixed with water, by way of experiment. The uſual ſymptoms of a gonorrhœa enſued, together with a diſcharge which had the ſame appearances and alterations of colour, as the matter of the gonorrhœa virulenta. We have already ſtated that the ſame circumſtances moſt frequently attend the employment of bougies.

In the generality of inſtances, the diſcharge does not proceed from any great extent of the urethra, not from more than an inch, or an inch and a half of that part of the paſſage, which is neareſt the orifice in the glans penis. This diſtance was what Mr. Hunter uſed to name the ſpecific extent of the inflammation. Before this celebrated ſurgeon flouriſhed, it was commonly ſuppoſed, that the matter came from the whole of the urethra, and even from Cowper's glands, the proſtate, and the veſiculæ ſeminales. Due attention to the ſymptoms, however, makes this idea ſeem quite improbable. If, for example, every part of the urethra, beyond the bulb, or if the bulb itſelf contributed to the diſcharge, the matter would be propelled out of the paſſage in the ſame manner as the ſemen, that is to ſay, by a ſudden convulſive kind of action. It is well known that nothing can lodge in the bulb of the urethra, without immediately putting that part of the canal into action, particularly when in a ſtate of irritation and inflammation. A drop of urine is not allowed to remain there, and if ſimple warm water be injected thus far, it is inſtantly forced out by the action of the acceleratores urinæ muſcles. Therefore it ſeems rational to conclude, that if the membranous and bulbous parts of the urethra, Cowper's glands, the proſtate, and the veſiculæ ſeminales, all had a ſhare in forming the matter, no ſooner would a certain quantity have collected in the bulb, than an immediate expulſion would be occaſioned by the muſcles of the part. No ſymptom of this kind, however, is uſually obſerved, although it occaſionally happens, that the acceleratores urinæ are affected with ſpaſmodic contractions, which are particularly diſpoſed to occur juſt after the patient has been making water, and do not ſeem to have any dependance on the diſcharge.

Mr. Hunter has taken notice that when the inflammation is violent, ſome of the veſſels of the urethra often give way. Hence a hemorrhage ariſes, which is moſt profuſe, juſt after the patient makes water, though it alſo continues at other times. Sometimes the blood is inconſiderable in quantity, and only juſt ſufficient to give a red colour to the matter. The erections, which are ſo frequent in this complaint, are apt to occaſion an extravaſation of blood, a ſymptom which is always attended with an increaſe of the pain felt at the time of making water; but the bleeding always in the end leſſens the inflammation, and tends to the relief of the patient.

The inflammation, accompanying a gonorrhœa, is attended with ſeveral of the characters of common inflammation; but yet it differs alſo from the latter affection in many reſpects. It does not excite any pulſatory ſenſation; it cauſes little pain, except what ariſes from the irritation of the urine and the tenſion of the parts; and the inflammatory irritation ſeldom extends beyond the affected ſurfaces. The reaſon of ſo large a quantity of pus being ſecreted, in conſequence of ſo moderate an inflammation, has been attributed to the parts being ſuch as naturally ſecrete, ſo that they readily alter the natural into a morbid ſecretion.

Although the inflammation of a gonorrhœa is commonly moderate, there are inſtances in which it is exceedingly ſevere, and extends into the reticular texture of the ſurrounding corpus ſpongioſum urethræ, particularly of that which is near the glans penis. Sometimes the inflammation advances further along the corpus ſpongioſum, and occaſions a ſwelling, or extravaſation of coagulating lymph, which is the cauſe of chordee. We have already ſtated that the inflammation occaſionally gives riſe to abſceſſes of the glands of the urethra, particularly of thoſe in the perinæum.

It is not decidedly known in what manner the diſeaſe communicates itſelf to the urethra. Some ſuppoſe that the inflammation creeps from the glans penis to the edges of the orifice of the urethra, and thence further into the paſſage. Theſe reaſoners will not allow the probability of a common opinion, that ſome of the infectious matter gets into the urethra at the time of coition. At all events it ſeems clear, that none of the contaminating fluid can get as far as the diſeaſe extends in ordinary inſtances, much leſs in others, where the affection reaches a great way towards the bladder. There are ſome facts which tend to prove that the ſimple application of the infectious matter to the end of the penis may give riſe to a gonorrhœa. A caſe related by Mr. Hunter in his treatiſe on the venereal diſeaſe, ſeems to confirm the truth of what we have mentioned.

As we have already obſerved, the complaint ſeldom extends further along the urethra, than about an inch and a half, or two inches. Mr. Hunter thought, that this part of the canal appeared to be moſt ſuſceptible of the particular kind of inflammation brought on by the infection, and it conſtituted, what he uſed to term, the ſpecific diſtance of the diſorder. However, neither the ſenſations of which the patient complains, nor the irritation of the parts, are confined to the real ſeat of the diſeaſe. The neighbouring parts are often affected with a variety of ſymptoms, of a nature more or leſs ſevere, ſuch as uneaſineſs, and even pains every where about the pubes, ſcrotum, perinæum, anus, and hips. It is often neceſſary to ſuſpend the teſticles, which become ſo irritable, that the leaſt accident, or exertion, which, in other circumſtances, would have no effect, makes them ſwell. It frequently happens that the glands in the groin are ſympathetically affected; they ſwell and inflame, though they do not commonly ſuppurate. Caſes alſo occur in which the irritation extends to the buttocks, thighs, and abdominal muſcles, occaſioning acute pain, ſwelling, and extreme ſoreneſs of the parts, and putting the patient under the neceſſity of always continuing in an horizontal poſture. Theſe ſymptoms, however, are not ſtrictly inflammatory: if the patient be bled, his blood does not exhibit the inflammatory cruſt, and the conſtitution is little or not at all affected.

When the caſe, independently of the affections ariſing from ſympathy, is not more violent than what has been deſcribed, it is called a common gonorrhœa; but the violence of the eſſential ſymptoms of the diſeaſe will be more or leſs conſiderable, according as the patient is more or leſs ſuſceptible of ſuch complaints as depend upon irritation. Thus, in particular habits, the inflammation does not confine itſelf to the ſpecific diſtance, but reaches all along the urethra. Severe pain is alſo frequently experienced in the perinæum. Sometimes the acceleratores urinæ muſcles are affected with the ſpaſmodic contractions, of which ſome mention has already been made. Such ſpaſm is particularly apt to come on when the patient has juſt finiſhed making water; it ſhews itſelf by the manner in which the laſt drops of urine are expelled; and it is generally attended with contractions of the erectores muſcles. Sometimes the inflammation is ſo great as to occaſion a ſwelling, and even an abſceſs in the cellular membrane. It has already been obſerved, that the moſt common ſituation of ſuch ſuppuration is in Cowper's glands; but the ſmall glands of the bulb may alſo be affected in a ſimilar manner, and the irritation, in certain inſtances, is found to extend even to the bladder itſelf.

When the latter organ is once affected, it becomes more ſuſceptible of every kind of irritation, ſo that very diſtreſſing complaints are apt to be produced. It is no longer capable of bearing the degree of diſtention of which it is capable in the healthy ſtate. Hence the patient cannot hold his water in the uſual way; but no ſooner does the inclination to diſcharge it ariſe, than he is immediately compelled to make the evacuation, notwithſtanding the ſevere pain, which, while the urine is eſcaping, is felt in the bladder, and eſpecially about the glans penis. This pain has been compared with what is experienced in a fit of the ſtone, and it laſts for ſome time after the evacuation is completed.

The ureters, and even the kidnies, are ſometimes ſympathetically affected, when the bladder is conſiderably inflamed or irritated. Such an occurrence, however, is exceedingly uncommon. Mr. Hunter mentions his having ſeen an inflammation of the peritonæum brought on by a ſevere affection of the bladder in gonorrhœa; and others have obſerved a violent inflammation of the kidnies from the ſame cauſe. (See Encyclopédie Méthodique partie Chirurgicale, tom. 1. p. 584.) It has already been mentioned that a chordee is one of the occaſional effects of a gonorrhœa. It ariſes in general from inflammation; but in ſome caſes it appears to be entirely of a ſpaſmodic nature.

When the inflammation is not confined to the urethra and its glands, but ſpreads further, it attacks the ſubſtance of the corpus ſpongioſum, where it occaſions an extravaſation of coagulating lymph, which, uniting the cells together, makes the urethra incapable of yielding and being ſtretched in the ſame degree as the corpora cavernoſa. Hence, during an erection, the penis becomes bent forward. The adheſion of the cells of the corpus ſpongioſum urethræ together, which is the cauſe of chordee, in general, comes on in conſequence of mere inflammation of the canal; but occaſionally it is the effect of a ſpecies of inflammation, which is ſeen accompanying certain ill-conditioned chancres. A chordee often continues after all the other ſymptoms of a gonorrhœa have quite ceaſed.

A chordee is ſometimes altogether ſpaſmodic, in which caſe it is ſeen to diſappear and re-appear alternately, at indeterminate intervals. At one time the erections, which are ſo common in caſes of gonorrhœa, happen without being attended with any curvature of the part; while at other periods the chordee takes place in a great degree; the intervals of time between theſe changes being ſometimes remarkably ſhort.

A ſwelling of the teſticles is a frequent conſequence of a gonorrhœa. It may happen in any ſtage of the diſeaſe; but, perhaps, it takes place moſt frequently when the complaint is on the decline. It was conſidered by Mr. Hunter as an affection ariſing from ſympathy. It is ſeen attending any kind of irritation in the urethra, whether occaſioned by injections, bougies, or any other circumſtance. In many caſes, the ſwelling comes on and diſappears very ſuddenly, or ſeems to leave one teſticle to attack the other.

The ſwelling of the teſticle generally begins with a ſoft, pulpy tumefaction of its glandular part, which becomes rather painful when handled. The tumour afterwards increaſes in ſize and firmneſs, and produces conſiderable pain. The inflammation ſeldom ends in ſuppuration, though ſome inſtances of this kind are met with. The epididymis (eſpecially its lower end) is uſually the hardeſt part; but, frequently, the induration and ſwelling attack the whole of the epididymis, and form a ſort of knob at its upper part. The ſpermatic chord alſo is often affected, eſpecially the vas deferens, which is thickened, and exceedingly tender. Sometimes the veins of the teſticles are varicoſe.

The inflammation of the teſticle, as well as that of the urethra, is frequently attended with ſympathetic ſymptoms of irritation in other parts; for inſtance, pain at the lower end of the ſpine, a ſenſe of weakneſs in the loins, colic pains, nauſea, flatulence, diſorder of the digeſtive organs, &c.

The ſwelling of the teſticle is noticed to take place remarkably often juſt when the pain in the urethra has ſubſided, and the diſcharge has ſtopped; or elſe the truth is, that on the teſticle becoming affected, the ſymptoms of irritation in the urethra immediately ceaſe. Here it is ſomewhat difficult to determine which is the cauſe, and which the effect. However, it is worthy of remark, that it is not uncommon for the teſticle to begin to ſwell at the very moment when the inflammation of the urethra, and the diſcharge, are becoming worſe. Sometimes the epididymis alone is affected; ſometimes only the vas deferens; and, on other occaſions, only the ſpermatic chord. No reaſon can be aſſigned, why one of theſe parts ſhould be affected rather than the reſt. The inflammation of theſe organs is frequently attended with a ſtrangury, eſpecially when the diſcharge is ſuppreſſed; and, indeed, it is remarked, that the ſtoppage of the running generally brings on a tendency of that diſtreſſing complaint.

Another occaſional effect of a gonorrhœa is a ſwelling of the lymphatic glands in the groin, a ſymptom, which is of the ſame nature as the inflammation of the teſticle, but much more common. It has been ſuppoſed that the tumefaction of the glands depends on the abſorption of ſome of the matter from the urethra; but Mr. Hunter contended againſt this opinion. He thought that, in gonorrhœa, the matter was ſeldom abſorbed, and he derived this ſentiment partly from ſeeing that a lues venerea was ſeldom the conſequence of this diſeaſe. However, this argument will have no weight with thoſe practitioners, who diſbelieve in the doctrine that the poiſons of gonorrhœa and the venereal diſeaſe are of the ſame nature. Another conſideration, which influenced Mr. Hunter, will meet with more general approbation. It was the fact, that any ſimple mechanical irritation of irritable organs is capable of exciting an inflammation of their abſorbents, and of the glands to which ſuch veſſels run. Now, ſince the lymphatics and their glands uſually inflame before ſuppuration has taken place in the part originally affected, and their inflammation often ſubſides as ſoon as this laſt occurrence begins, we muſt conclude, that the ſwelling of the inguinal glands, in gonorrhœa, ariſes altogether from the irritation in the urethra. It is obſerved alſo, that ſuch ſwellings almoſt always admit of reſolution, while thoſe which originate from the abſorption of venereal matter from chancres very frequently ſuppurate, burſt, and turn into ſyphilitic ulcers. It is true, however, that ſwellings of the inguinal glands, induced by the irritation of gonorrhœa, do ſometimes end in abſceſſes and ſores; but no lues venerea follows, nor is mercury requiſite for the cure.

Another ſympathetic affection, ſometimes attendant on a clap, is a ſwelling of the abſorbent veſſels themſelves. In ſome inſtances, this ſymptom accompanies the ſwelling of the glands. It makes its appearance in the form of a hard, painful cord, which, proceeding from the prepuce, extends along the dorſum of the penis, ſometimes as far as the groins. This effect is not the conſequence of the abſorption of matter; for it is ſeen attending other irritations in the urethra, where no ſuſpicion of any irritating or poiſonous matter being taking up by the lymphatics can be entertained by any kind of reaſoning whatſoever. The ſymptom is ſometimes brought on by the employment of bougies, in the treatment of ſtrictures. It was for a long while ſuppoſed, that the matter which is diſcharged from the urethra, in caſes of gonorrhœa, was furniſhed from ulcers in this canal; but obſervation at length detected, that the opinion was deſtitute of all foundation. Dr. William Hunter is reputed to have been the firſt who aſſerted, that in gonorrhœa no ulcers exiſted in the urethra, and he is ſaid to have begun to inculcate the fact in his lectures about the year 1750. This celebrated phyſician had derived his ſentiment from ſome particular caſes which he had ſeen, where a large quantity of pus had been formed upon the ſurface of the viſcera, without any ulceration of theſe parts whatſoever. In 1753, his brother, Mr. John Hunter, had an opportunity of diſſecting the bodies of two malefactors, who were executed, while it was known that they were affected with a ſevere gonorrhœa. After a moſt careful examination, no ulceration could be diſcovered: the urethra of each was merely found to be rather redder than natural, particularly near the glans penis. Mr. Hunter afterwards opened the urethra of many patients who had died with gonorrhœa upon them, and he never could find any veſtiges of ulceration. It conſtantly appeared, that the membranous lining of the canal, near the glans penis, was redder than uſual, and that the lacunæ were frequently filled with pus. Morgagni is ſaid to have remarked the ſame fact. (De Sedibus et Cauſis Morborum. Epiſt. 44. § 7.)

As an attempt has been made by a late writer, Dr. Swediaur, to transfer the honour of the diſcovery from the Hunters to Morgagni, we deem it our duty to obſerve, that we cannot diſcover any accuracy, or juſtice, in the doctor's ſtatement, ſince Morgagni's work was not publiſhed till 1761.

Although there can now remain no doubt, that in gonorrhœa there are no ulcers eſſentially, or commonly preſent in the urethra, to furniſh the matter which is diſcharged, yet Mr. Hunter himſelf has explained, that a ſore, occaſioned by the burſting of an abſceſs in one of the glands of this paſſage, is ſometimes produced. This kind of ulceration, however, never takes place till long after the commencement of the running, and it is quite of a different nature from ſuch ſores as were fancied to be the cauſe of gonorrhœa.

We ſhall now conſider the identity of the gonorrhœa and venereal poiſons. It has been repreſented by ſome ſurgical authors, that the eſſential difference between gonorrhœa and the venereal diſeaſe depends upon the circumſtance of the firſt complaint being an affection of a ſecreting ſurface. Many other writers, and we may add, the generality of enlightened practitioners in this country, contend, that the two diſeaſes originate from different poiſons, a ſentiment which is ſupported by the ſtriking diſſimilarity of the two affections, and the wide difference of their modes of cure.

Such authors, as maintain the doctrine of the two complaints being the conſequence of different diſtinct poiſons, found their arguments upon various circumſtances. Firſt, the hiſtory of theſe diſeaſes, and of their progreſs in different countries. Secondly, the phenomena peculiar to each diſorder. Thirdly, the remedies neceſſary for the cure.

It is aſſerted, that the venereal diſeaſe and gonorrhœa did not make their appearance in Europe at the ſame period; but that the former was many years antecedent to the latter. The ſame thing is ſtated to have happened in other parts of the world, whither Europeans have conveyed the venereal virus. For inſtance, the venereal diſeaſe was known in China almoſt immediately after it had made its appearance in Europe; yet it is remarked by Aſtruc, that at the time when he wrote, gonorrhœa was a malady which had only been very recently obſerved among the Chineſe. Alſo, in the South-ſea iſlands, diſcovered in modern times, where both the venereal diſeaſe and gonorrhœa were unknown before the landing of European navigators, but where theſe maladies were afterwards diffuſed, gonorrhœa was not noticed till ſeveral years after ſyphilitic diſorders had begun to ſhew themſelves. Claps are ſaid to have been yet unknown to the natives of the South-ſea iſlands, at the period when captain Cook was performing his ſecond voyage. (Duncan's Medical Caſes and Obſervations.) All theſe circumſtances have been adduced to prove the difference between that virus which gives riſe to the venereal diſeaſe, and that from which gonorrhœa has its origin.

On the other hand, the circumſtances attending the commencement of the venereal diſeaſe in theſe remote countries, led Mr. Hunter to draw a concluſion diametrically oppoſite to the one deduced by the foregoing claſs of reaſoners; for, he obſerves, that it is almoſt impoſſible for a man to have a chancre during a voyage of ſeveral months, without the whole of the penis being deſtroyed, while it is well known, that a gonorrhœa may laſt an immenſe time, without loſing the character of being virulent. It is related in the account of captain Cook's voyage, that the inhabitants of Otaheite, who were infected with the gonorrhœa, went up the country and got well; but that when the conſequence of the malady was the venereal diſeaſe, the latter was incurable. Hence it is inferred, that the complaint which the Otaheiteans contracted was the gonorrhœa, ſince chancres and venereal affections would never have yielded to the ſimple means which were adopted. Beſides, if the diſorder had conſiſted of chancres, and the natives of Otaheite had been acquainted with the mode of curing ſuch ſores, it is contended, that they would likewiſe have underſtood how to cure other venereal ſymptoms. We find, alſo, from the peruſal of captain Cook's third voyage, that the venereal diſeaſe afterwards raged in all its forms in the iſland of Otaheite. Now, ſince there is no document to ſhew, that the gonorrhœa was again introduced into that country, ſubſequently to Cook's ſecond viſit, it is concluded, that every form of the venereal diſeaſe which has been obſerved there has been derived from one ſource, which, in all probability, was a gonorrhœa.

Mr. Hunter mentions a gentleman who had a gonorrhœa thrice, of which he was cured without mercury. About two months after each infection, he had ſymptoms of lues venerea. The firſt were ulcers in the throat; the ſecond were blotches on the ſkin; both which forms of the diſeaſe yielded to mercury. Thirdly, two punctures were made on the penis, with a lancet dipped in the matter of a gonorrhœa. One of theſe produced, on the part of the prepuce where it was made, a red, thickened ſpeck, which increaſed and diſcharged ſome matter. This ſuppoſed chancre healed on having its ſurface repeatedly deſtroyed by cauſtic. The other puncture was made on the glans, where it was followed by a pimple, full of yellowiſh matter. This pimple was touched with cauſtic, and healed in the ſame way as the ſore on the prepuce. Four months afterwards the chancre on the prepuce broke out again; then it healed, and returned. This it did ſeveral times; but always healed without any application to it. While the ſores remained on the prepuce and glans, a bubo formed in the groin. A ſufficient quantity of mercury was given to cure the gland locally, but not to prevent the conſtitution from being affected. Two months after the cure of the bubo, a venereal ulcer, according to Mr. Hunter, formed on one of the tonſils. This was cured by mercury; but the medicine was purpoſely left off as ſoon as the ſore was ſkinned over, in order to ſee what parts would next be affected.

About three months afterwards, copper-coloured blotches made their appearance in the ſkin, and the ulcer on the tonſil recurred. This diſeaſe was again only palliated by mercury; but the complaints returned in the ſame ſituation as before; and were ultimately cured by a proper quantity of mercury.

On the other hand, doubts muſt exiſt, concerning this account of the matter of gonorrhœa, when the following circumſtances are taken into conſideration:

1ſt. It is impoſſible to ſay what time may elapſe between the application of venereal poiſon to the penis, and the commencement of ulceration. Therefore, Bougainville's ſailors, alluded to by Mr. Hunter, might have contracted the infection at Rio de la Plata; but actual ulcers on the penis might not have formed till about five months afterwards, when the ſhip arrived at Otaheite. 2dly. The ſecond argument adduced by Mr. Hunter is certainly inconcluſive. Every ulcer in the throat is not regularly venereal. A common ulcer may heal while the patient is uſing mercury. Hence the cure, apparently accompliſhed by this medicine, is no proof that the complaint was ſyphilitic. 3dly. The laſt fact of inoculation is undoubtedly very ſtrong. But, though the inſertion of gonorrhœal matter, or any other morbid matter, beneath the cuticle, will undoubtedly produce troubleſome local complaints, may we not doubt that the ſores, in the above caſe, were actually venereal ones? Can we implicitly depend on the continence of the ſubject of the above remarkable experiments, during the long ſpace of four months, between the healing of the ſore on the prepuce, and its recurrence? If we cannot, the inference, in regard to the power of gonorrhœal matter to communicate the venereal diſeaſe remains uneſtabliſhed. How much more concluſive in this reſpect, the experiments would have been, had the inoculation been practiſed on any other part but the penis. If the matter of gonorrhœa be capable of communicating the venereal diſeaſe, why does not the diſcharge commonly produce chancres on the glands and prepuce, with which parts it muſt lie in contact a very conſiderable time in every caſe? Why alſo does not the preſence of a chancre frequently cauſe a gonorrhœa? If the infection of gonorrhœa, and the venereal diſeaſe, be really of the ſame identical nature, certainly, it ſeems very extraordinary, that the former complaint ſhould receive no benefit from mercury, and the latter diſeaſe invariably require this ſpecific remedy.

With reſpect to the venereal diſeaſe and gonorrhœa having ariſen in Europe and elſewhere at different periods, it has been obſerved by ſuch writers, as incline to the belief in the identity of the virus of the two affections, that every kind of contagious diſeaſe appears with greater violence in new-infected countries, than in other ſituations where it has been a conſiderable time endemial. In this manner, an endeavour, which, in our opinion, is quite unſucceſsful, is made to explain the cauſe why the gonorrhœa generally did not make its appearance till a long while after the venereal diſeaſe had ſhewn itſelf in much worſe ſhapes. The ſame claſs of reaſoners alſo aſſert, that, notwithſtanding the diligent enquiries of many able men, there is ſtill a degree of doubt concerning the exact time when theſe diſeaſes originated, and, of courſe, concerning the point, whether one of them actually exiſted a long while before the other. As we ſhall have occaſion to treat of the origin of the venereal diſeaſe hereafter (ſee Lues Venerea), we ſhall not enter into this diſquiſition in the preſent article. We may be permitted, however, to expreſs our ſuſpicions, that diſcharges from the urethra muſt have been occaſional diſeaſes from time immemorial. Whether there be a ſpecies of gonorrhœa truly venereal, that is to ſay, one which depends upon the ſame virus, as ſyphilis, there may for ever remain doubts; but, that there are claps or diſcharges which ariſe from no poiſonous or infectious matter whatſoever, but altogether from mere irritation in the urethra, as, in certain caſes of ſtrictures, is certain and undiſputed. Theſe gonorrhœas muſt have prevailed as long as that canal has been liable to various kinds of irritation.

One argument adduced againſt the identity of the virus, is derived from the ſtriking difference obſervable in the progreſs and ſymptoms of the two diſeaſes. When the venereal diſeaſe is neglected, it always grows worſe and worſe, and ſooner or later brings on the patient's diſſolution. On the contrary, a gonorrhœa tends to a natural cure, and, though left to itſelf, commonly ends in a favourable way.

The advocates for the identity of the poiſon, however, contend, that, in order to account for this laſt fact (which they ſtate is not without exceptions), it is by no means neceſſary to ſuppoſe a different virus. They bring into conſideration the circumſtance of gonorrhœa depending upon an inflammation of the ſurface of the urethra, and not ulceration; and they maintain, that the abſorption of the venereal poiſon generally happens much more eaſily from ulcerated ſurfaces, than from ſuch as are ſimply inflamed. This mode of reaſoning is brought forward as explanatory of the cauſe why, in the majority of caſes, a gonorrhœa remains entirely a local complaint, and admits of a ſpontaneous cure, while the venereal diſeaſe is always prone to extend itſelf, and ſpread from one part of the body to another.

An argument againſt the identity of the virus is alſo founded on the reflection, that the venereal diſeaſe is only capable of communicating the venereal diſeaſe, and gonorrhœa of imparting gonorrhœa. The partizans of the doctrine which imputes this latter affection to the venereal virus, acknowledge, that things do uſually correſpond with the ſtatement juſt now given; but they aſſert that the contrary caſe is alſo frequently obſerved. They remark, that we may eaſily convince ourſelves of this circumſtance, by a fact which is well known to practitioners, namely, that when perſons, who have a gonorrhœa, are not particularly careful to keep the glans and prepuce clean, chancres are very apt to form upon theſe parts, and by one ſuch ſore the whole ſyſtem may become infected. It is alſo aſſerted, that, independently of the formation of any chancre, there are caſes proving, that the venereal diſeaſe may be the conſequence of a gonorrhœa, and that every ſurgeon of extenſive practice muſt meet with inſtances of this kind. One of the moſt remarkable on record, is that related by Mr. Hunter; and it having been already noticed by us in the preſent article, we need not dwell upon it again.

With reſpect to chancres ariſing from the matter of gonorrhœa being in contact with the glans and prepuce, we do, undoubtedly, ſee both men and women who have claps and chancres together; but, in our opinion, it is moſt rational to impute the ſores to the application of venereal pus from chancres, together with the gonorrhœal matter, at the time of coition. We have no doubt that this act is often performed, when, between the two parties, both kinds of infection are preſent.

Certainly it ſeems extraordinary, that if the virus be of the ſame nature in both caſes, the two effects ſhould not always occur in the ſame patient. We ought naturally to expect, that when a gonorrhœa makes its appearance firſt, it would always be the cauſe of a chancre; and that when a chancre is the firſt ſymptom, it would invariably be the occaſion of gonorrhœa. We diſmiſs from preſent conſideration the aſſertion of ſuch writers as defend the identity of the virus, that, in ſome few inſtances, one malady does become the cauſe of the other. Mr. Hunter ſuſpected, that the irritation of one of the parts, forming the ſeats of the two diſeaſes, became the preſervative of the other. He thought, that when the urethra inflames and diſcharges matter, the adjacent external parts might, on that very account, be exempt from a diſeaſe which they would otherwiſe inevitably contract, by reaſon of the effect of the very virus which gave riſe to the gonorrhœa. The ſame celebrated writer alſo entertained a ſuſpicion, that when a chancre attacks the glans, or prepuce, the urethra might become inſuſceptible of the irritation, which, without the external diſeaſe, would certainly lead to a diſcharge from that canal.

This mode of explanation appears to us ſomewhat theoretical. We are of opinion, alſo, that in arguing in this way, the advocates for the identity of the virus only bring forward the ſhadow, inſtead of the ſubſtance of reaſon. In fact, they ſay nothing more than that ſuppoſed venereal matter cannot make the external parts of the penis ulcerate, becauſe there is an irritation in the urethra; and that the urethra cannot be affected with gonorrhœa, becauſe a chancre already occupies the external parts. If this reaſoning be not hypothetical and fanciful, we cannot conceive what arguments can ever be conſidered ſo. They who talk in this manner, inadvertently fall into difficulties, and make one opinion inconſiſtent with another. Thus, they have already told us, that, occaſionally, a chancre is apt to occur, when patients with gonorrhœa neglect to keep the glans and prepuce clean; yet, according to their principles, a clap renders the external parts inſuſceptible of infection, and, of courſe, there would be no need of cleanlineſs as a preſervative. We think that the weakneſs of the argument muſt be obvious to the youngeſt ſtudent, who, on his entrance into any venereal ward of an hoſpital, is almoſt ſure of immediately finding a patient who has at the ſame time both chancres and gonorrhœa.

The different treatment required by gonorrhœa and the venereal diſeaſe, is another argument againſt the identity of the virus, mercury being unneceſſary in claps, and the ſole ſpecific in the other complaint. The partiſans of the oppoſite opinion endeavour to diminiſh the force of this fact, by adverting to the different ways in which the two diſeaſes affect the parts which are attacked, and by maintaining that no juſt inference can be drawn from the difference of treatment, while the particular action of mercury, on various parts affected with the venereal poiſon, is not underſtood. They alſo contend that, though mercury may have no effect in gonorrhœa, when uſed in the ſame way as for other venereal affections, yet, when applied to the urethra itſelf, it ſerves to moderate the ſymptoms, and accelerate the cure.

Having ſeen the calomel injection employed in ſome hundreds of caſes, with leſs benefit than the common vitriolic one, we cannot aſſert to the laſt obſervation. The other remarks, being bare opinions, may be received or not, as the judgment of the reader may incline him; but, for our own part, we have no heſitation in refuſing them a place among ſuch information as is founded on rational evidence.

We ſhall now ſay a few words, reſpecting the time, between the application of the infection and the beginning of its effects.

In the greater number of diſeaſes, a certain ſpace of time always elapſes between the application of the cauſe and the firſt appearance of the effect. The time when a gonorrhœa begins, after contamination, varies conſiderably in different caſes. In ſome examples, the poiſon takes effect in a few hours, as Mr. Hunter has ſeen two or three times; while, in other inſtances, the complaint does not ſhew itſelf till the end of five or ſix weeks. There are alſo caſes to be met with, in which the diſorder begins at all the intermediate periods. It is calculated, that the moſt common time of its origin is in the ſpace between the ſixth and twelfth day. In one inſtance, in which the malady did not commence till the end of ſix weeks, it was noticed by Mr. Hunter, that the affection was preceded by various ſymptoms of irritation, and uncommon ſenſation, in the parts. Hence, this celebrated author concluded, that the virus ſeldom, or never, remains ſo long inactive; but that the inflammatory ſtate may exiſt a good while before ſuppuration takes place. The delay in the commencement of the diſcharge, however, may be owing to cauſes which are not underſtood, and this is very likely to be true, if we conſider that ſome caſes of gonorrhœa do not begin for five or ſix weeks after infection, and yet are not preceded by any remarkable ſymptom whatſoever.

The obſervations already made in a preceding part of this article, muſt have apprized the reader, that diſcharges from the urethra may originate from more cauſes than one, and from more irritations than that which is produced by one particular kind of virus. There are ſometimes ſpontaneous diſcharges from this paſſage, while no immediate cauſe whatever is aſſignable. Such inſtances as occur independently of a ſpecific gonorrhœal, or, according to the Hunterian doctrine, the venereal virus, have been termed *ſimple* or *benign*. Some aſſert, that theſe caſes may be known by their coming on immediately after coition, and it is violent from the very beginning; while the virulent gonorrhœa does not commence till after ſome days, and grows gradually worſe. However, this criterion is inſufficient: ſimple gonorrhœas are not always owing to coition, nor are they always ſudden in their appearance.

Mr. Hunter has ſeen the urethra ſympathize with the gums in dentition, and all the ſymptoms of gonorrhœa affect the ſame infant ſeveral times. The author of the article *Gonorrhée*, in the Encyclopédie Méthodique, alſo mentions his having ſeen two female children, who were affected during dentition with a diſcharge from the pudenda, attended by a certain degree of inflammation, and pain in making water.

We ſhall next introduce a few remarks on the effect of the diſcharge on the parts producing it.

It was formerly not an uncommon opinion, that the diſcharge was a means employed by nature for carrying off the virus occaſioning the complaint, and thus bringing about a cure. However, it is impoſſible for this to be true, with reſpect to inflammations, which ariſe from a ſpecific virus; for, ſuppoſing the ſuppuration could waſh away all the poiſon, cauſing the original irritation, yet, as all the matter afterwards ſecreted is equally virulent, no good would be done; the irritation, according to the preceding idea, would be perpetuated, and, of courſe, the diſcharge. This laſt occurrence, however, we need hardly remark, is not the caſe. The affection of the urethra in gonorrhœa is not kept up by the matter, but by the ſpecific quality of the inflammation itſelf, which, in all probability, can never continue beyond a limited time, ſince the ſymptoms at length ſpontaneouſly ſubſide. Had the infectious matter, which is formed in the courſe of the diſeaſe, the power of protracting the original irritation, the diſorder would have no termination.

In gonorrhœa, as in many other diſeaſes, the morbid action of the parts affected cannot go on for a long while in the ſame way. After having increaſed in violence to a certain degree, it naturally tends to become weaker; and the ſymptoms of the diſorder which depend upon ſuch action, at length, entirely ceaſe. The time of this ceſſation will vary according to circumſtances; for if the irritated parts be very ſuſceptible of the ſpecific irritation, the diſeaſed action muſt be more violent and laſting; but, in all caſes, this difference is always owing to ſome particularity of conſtitution, and not to any peculiarity of the virus.

The reader is aware that Mr. John Hunter regarded the gonorrhœa as one form of the venereal diſeaſe. It was the opinion of this diſtinguiſhed man, that the venereal diſeaſe was only capable of a natural ceſſation, when it occupied a ſecreting ſurface, from which it produced pus. He believed that when the part attacked was not a ſecreting one, and an ulcer was formed, the diſeaſe would of itſelf go on for ever. He referred this difference between gonorrhœa and a chancre, however, more to the difference in the mode of action, than to that of the affected ſurfaces; for when the venereal virus produces an ulcer upon a ſecreting ſurface, as it ſometimes does upon the tonſils, and even the urethra itſelf, ſuch ſores are not more diſpoſed to heal, than if they were ſituated any where elſe in the body.

It is ſometimes obſerved, in caſes of gonorrhœa, that the parts which were firſt irritated get well, while the irritation is communicated to another part of the ſame ſurface, as happens, when it leaves the urethra near the glans, and affects that part of the canal which is further on towards the bladder.

Admitting that every gonorrhœa is capable of getting well, without ſurgical aſſiſtance, it may be doubted whether a perſon, who already has a gonorrhœa, is ſuſceptible of the irritation of freſh gonorrhœal matter, or that the clap which exiſts could be augmented by its application. Mr. Hunter extended the ſame obſervation to every form of the venereal diſeaſe; and he ſtates, that the matter of gonorrhœa, or of a chancre, put on an ulcerated bubo, does not in the leaſt retard the cure, although, if venereal matter be applied to a common ſore, the venereal irritation will frequently be excited. Such facts are ſtrongly in favour of the opinion, that the matter of gonorrhœa has no effect in keeping up the complaint. The urethra is neither irritated by the infectious matter which it ſecretes, nor can the irritation already exiſting laſt beyond a certain period. Even were freſh matter applied to the urethra, the complaint would probably get well with equal quickneſs.

Mr. Hunter extended the idea further, and even conceived that a freſh gonorrhœa could not be contracted, were freſh virus applied to the parts affected, at the period when the cure was juſt on the point of being completed. He thought that, in time, the parts might be ſo habituated to the impreſſion of the virus, as to become inſenſible of it, and they muſt have regained their natural and original ſtate, ere the infection can again have ſuch effect upon them as to reproduce the complaint.

The foregoing opinions do not reſt altogether upon theory: they are alſo founded on experience and obſervation. Men, who have juſt had a gonorrhœa, have frequently been known to expoſe themſelves to be infected again without any recurrence of the complaint taking place, while other healthy perſons, who had connection with the ſame woman, have immediately caught the malady. Perhaps, it is on the ſame principle, that the firſt gonorrhœa is generally the moſt violent, and that ſuch perſons as are often affected with claps have them more and more mildly, particularly when the intervals are ſhort.

In corroboration of theſe ſentiments, Mr. Hunter relates ſeveral caſes, among which is the following: a married man, who, for ſeveral years, had had no connection with any woman except his own wife, happened to meet with an old acquaintance, who gave him a ſevere gonorrhœa, though ſhe declared her belief that ſhe was quite well. Both adopted ſome means of cure; but continued to cohabit together during the treatment. The man got well, and it was preſumed that the woman was alſo cured. They continued to live together ſeveral months, without the former experiencing any inconvenience, or having any reaſon to ſuppoſe that there was ſtill any thing the matter with the latter. At length they parted, and the woman formed a new attachment. She had no ſooner made this laſt connection, than ſhe gave the new lover a gonorrhœa. She again conſulted Mr. Hunter, whom ſhe aſſured, that ſhe had never cohabited with any others, except the preceding two; and conſequently, if this be true, the infection of her laſt lover muſt have ariſen from the very ſame gonorrhœa, of which ſhe ſuppoſed that ſhe had been formerly cured. However, ſhe now uſed no remedies, and the man, after he was well, continued to cohabit with her for ſeveral months without receiving any new infection. But her old lover now returning, after a year's abſence, and thinking that, as ſhe was living regularly with the ſecond, there could be no danger, ventured to have connection with her; the conſequence was, that he caught another gonorrhœa.

Before deſcribing the treatment, it is proper to ſay a few words of the diſeaſe in women.

The gonorrhœa in females is not ſo complicated as in men, the parts affected being more ſimple and fewer in number. In women the diſeaſe is not ſo eaſy to be aſcertained, becauſe they are alſo liable to a complaint, called the fluor albus, which has ſome reſemblance. A mere running from the parts is not ſo much a proof of the exiſtence of an infectious gonorrhœa in a woman, as a diſcharge without pain in a man; and in the former the diſeaſe will often exiſt, while there is no increaſe whatever in the natural ſecretion from the parts. Nor can any criterion be deduced from the kind of matter, ſince the diſcharge of the fluor albus frequently puts on all the appearances of gonorrhœal matter. Neither is pain, nor any peculiarity in the ſenſations of the parts, neceſſarily attendant upon the complaint in women. Mr. Hunter alſo remarks, that the appearance of the parts often gives us but little information; for he frequently examined them in patients, who complained of all the uſual ſymptoms, ſuch as an increaſed diſcharge, pain in making water, ſoreneſs, &c. and yet he could perceive no difference in the look of the parts and of ſuch as are quite healthy. When the patient was not conſcious of any particular ſymptoms, or was diſpoſed to conceal her knowledge of them, Mr. Hunter thought that ſome judgment might be formed from her having had connection with men ſuppoſed to be unſound, and from her power of communicating the diſeaſe to others. However, it is acknowledged, that as this laſt circumſtance is derived from the teſtimony of another perſon, there are obvious reaſons why it ſhould not always be truſted.

When a woman contracts a gonorrhœa, the vagina muſt be firſt attacked, a part which is not endued with conſiderable ſenſibility. Frequently, however, the complaint extends much further, producing diſagreeable ſenſations and ſoreneſs of the inſide of the labia, nymphæ, clitoris, carunculæ myrtiformes, and meatus urinarius. The parts are ſometimes ſo ſore that the patient cannot bear them to be touched; ſhe can hardly walk; and a great deal of pain is experienced when the urine comes into contact with the ſore ſurfaces, as it muſt unavoidably do as often as the bladder is emptied.

When the diſeaſe extends to parts which are more ſenſible than the vagina, and more ſuſceptible of inflammation, women have nearly the ſame ſymptoms as men; a fulneſs about the parts, a diſcharge from the urethra, violent pain in making water, and great uneaſineſs from the preſſure on the parts in ſitting. Sometimes the bladder is alſo affected.

The inflammation frequently extends to ſome depth, running along the ducts of the glands, and affecting the glands themſelves, ſo as to occaſion hard ſwellings under the ſurface of the inſide of the labia. Theſe tumours often ſuppurate, and burſt near the orifice of the vagina. They reſemble the abſceſſes in the glands of the urethra in men.

The time in which a gonorrhœa may be cured is exceedingly variable, ſome caſes terminating in a week, while others continue for months under the ſame treatment.

According to Mr. Hunter, the object in the cure is to deſtroy the diſpoſition and ſpecific mode of action in the ſolids of the parts, and, as ſoon as that change is accompliſhed, the poiſonous quality of the matter produced will alſo be deſtroyed. Thus the diſeaſe may be cured though not always its conſequences.

A gonorrhœa is not capable of being continued beyond a certain time in any conſtitution, and when the complaint is violent and laſts a long while, it is owing to the parts being very ſuſceptible of ſuch irritation, and readily retaining it.

Since there is no ſpecific medicine for the gonorrhœa, it is very fortunate, as Mr. Hunter obſerves, that time alone will effect a cure. This celebrated ſurgeon was inclined to think, that, in caſes of gonorrhœa, medicines were ſeldom of ſervice, perhaps not more frequently than once in ten inſtances. With the idea, that every gonorrhœa cures itſelf, he gave certain patients pills of bread, which were taken with great regularity. Theſe perſons all got well; but Mr. Hunter thought that ſome of them were not cured quite ſo ſoon as they would have been, had artificial means been employed.

The ſurgical methods of cure conſiſt of internal remedies and local applications; but in putting any plan of treatment in execution, more attention ſhould always be paid to the nature of the conſtitution, or to any attending diſeaſe in the parts themſelves, or parts connected with them, than to the running itſelf.

The nature of the conſtitution is principally to be judged of from the local effects of the diſeaſe. Theſe are ſo different in different people as to require a great variety of treatment, a circumſtance, ſays Mr. Hunter, which has been too little attended to, every one endeavouring to attack the immediate ſymptoms, as if he had a ſpecific for a gonorrhœa.

We are firſt to conſider, whether the inflammation is violent or mild, common or irritable. When the ſymptoms are violent, but of the common inflammatory kind, which is to be judged of from the attending circumſtances, and particularly from the extent of the inflammation not exceeding the ſpecific diſtance, the local applications may be either of the irritating or ſoothing kind. In this example, irritating applications may be leſs dangerous, than when the inflammation is of the irritable ſort, and may have the effect of altering the ſpecific action, the parts afterwards recovering of themſelves, as from any other common inflammation. Mr. Hunter, however, expreſſes his belief, that the ſoothing plan is the beſt at the beginning.

When the inflammation is great, and of the irritable kind, no violence is to be uſed in the treatment, as the ſymptoms would thus only be increaſed. Mr. Hunter thought, indeed, that there were ſome caſes, which are exceptions to the latter remark, the great degree of inflammation ariſing entirely from a ſuſceptibility of this irritation, and not from any general irritability in the conſtitution. He confeſſes, however, that ſuch examples can ſeldom be diſcriminated.

When the ſymptoms run very high, nothing ſhould be done to ſtop the diſcharge, as, were it to be checked, the inflammation would ſtill continue, and no good be effected.

Mr. Hunter recommends us to alter the conſtitution, if poſſible, by remedies adapted to each diſpoſition, with a view to alter the actions of the parts ariſing from ſuch diſpoſitions, and reduce the diſeaſe to its ſimple form. If the conſtitution cannot be altered, we can only allow the action to wear itſelf out.

When the inflammation has conſiderably abated, and the diſeaſe only remains in a mild form, its cure may be attempted either by internal remedies, or local applications. If local means are uſed, violence is ſtill to be avoided, becauſe it may bring back the irritation. At this period (continues Mr. Hunter), gentle aſtringents may be applied with a proſpect of ſucceſs; or, if the diſeaſe has begun mildly, and there are no ſigns of an inflammatory diſpoſition, either of the common, or irritable kind, an irritating injection may be uſed, in order to get rid of the ſpecific mode of action quickly. Such application will increaſe the ſymptoms for a time; but, when it is left off, they will frequently abate, or wholly diſappear. In ſuch a ſtate of parts, aſtringents may be uſed: for the only thing to be done, is to procure a ceſſation of the diſcharge, which is now the principal ſymptom.

When the itching, pain, &c., are felt for ſome time before the diſcharge appears, Mr. Hunter rather prefers the ſoothing to the irritating plan of treatment. He ſuſpected, that thus the coming out of the diſcharge would be promoted, which occurrence he conceived was the firſt ſtep towards a reſolution of the irritation. He believed that, at all events, in this caſe, the employment of aſtringents would be bad practice, as, by preventing the diſcharge from taking place, they might prolong the inflammation, and protract the cure. Alſo, in caſes of ſtrictures, and of diſeaſed teſticles, he is adverſe to the uſe of aſtringents; for, ſays he, while the diſcharge laſts, both the other complaints are relieved.

The internal remedies commonly recommended in a gonorrhœa, may be divided into evacuants and aſtringents. The evacuants (ſays Mr. Hunter), are principally of the purgative, or diuretic kind, and theſe are not confined to any particular medicines, every practitioner ſuppoſing that he is in poſſeſſion of the beſt. Some uſe mercurial evacuants; whilſt others carefully avoid mercury in every form. The neutral ſalts have been given from the idea of their being cooling. Some of the profeſſion have chiefly kept to diuretics, perhaps with two views; firſt, as evacuants acting mechanically upon the urinary paſſages, ſo as to waſh away the matter; ſecondly, as ſpecifics. For this purpoſe, nitre has been given, a medicine which has always been thought to have great effect in leſſening inflammation, though Mr. Hunter had doubts concerning the truth of the opinion. Under every mode of treatment the patients always get well, and the cures are aſcribed by each practitioner to his own favourite method.

Mr. Hunter remarks, that "to keep the body open in moſt caſes, even when the patient is in other reſpects in health, muſt, no doubt, be proper; but what idea can we form of an irritation, produced all along the inteſtinal canal, curing a ſpecific inflammation in the urethra? Yet there are caſes where a briſk purge has been of ſervice, and even in ſome has performed a cure. But I ſuſpect, that, in ſuch caſes, the diſeaſe had been continued by habit only, and that this practice would not have ſucceeded in the beginning. A gentleman had a gonorrhœa, all the ſymptoms of which continued for two months, and by taking at once ten grains of calomel, which purged him moſt violently, he was almoſt immediately cured. The calomel could not have acted ſpecifically, but by a kind of derivation, that is, an irritation produced in one part, cured one that ſubſiſted in another; but even if it ſhould be granted, that in ſome conſtitutions purges have the power of making the ſolids leſs ſuſceptible of this irritation, it cannot be ſuppoſed they will have this effect in every caſe: in ſome conſtitutions, they might debilitate, increaſe irritability, and of courſe increaſe the ſymptoms. Theſe contrary effects muſt take place in different conſtitutions, in which a medicine has no ſpecific action. On the ſuppoſition of the cure being promoted by an evacuation from the blood, what ſervice can purging out ſome of the blood, in form of a ſecretion from one part, do to an inflammation of another part? On ſuch a ſuppoſition would not a ſweat, or an increaſe of ſaliva, by chewing tobacco, or ſtimulating the noſe by ſnuff, all tend equally to cure a gonorrhœa? But humours having been conſidered as the univerſal cauſe of every diſeaſe, eſpecially thoſe in which pus is formed, or a diſcharge produced, and purging having been ſuppoſed to be the cure for humours, purgatives were of courſe made uſe of in this diſeaſe; and as the patients have always been cured, the practice became generally eſtabliſhed.

"Thoſe who recommended mercury in this form of the diſeaſe, did it moſt probably from the opinion, that this medicine was a ſpecific for the venereal diſeaſe in all its forms. On this ſuppoſition, we can ſee ſome reaſon for their practice, as it would be abſorbed from the inteſtines, circulate through the inflamed veſſels of the urethra, and thereby deſtroy the venereal irritation. Here we can only ſuppoſe it to act by its ſpecific virtue; but I doubt very much of mercury having any ſpecific virtue in this ſpecies of diſeaſe; for I find, that it is as ſoon cured without mercury as with it; and where this medicine is only uſed as a purge, or purged off the next day, and therefore allowed to act merely upon the bowels, I cannot conceive that it could have any more effect upon the venereal inflammation in the urethra, than an irritation in the bowels ariſing from any other purgative. So little effect, indeed, has this medicine upon a gonorrhœa, that I have known a gonorrhœa take place while under a courſe of mercury ſufficient for the cure of a chancre. Whether the gonorrhœa aroſe from the ſame infection that produced the chancre I cannot ſay; nor can it be eaſily determined in ſuch caſes. Men have alſo been known to contract a gonorrhœa when loaded with mercury for the cure of a lues venerea; the gonorrhœa, nevertheleſs, has been as difficult of cure as in ordinary caſes." P. 72, &c.

With reſpect to diuretics, conſidered as evacuants, Mr. Hunter obſerves, that they may have the ſame general remarks made on them as have been offered in regard to purgatives. It is poſſible, ſays he, that ſpecific medicines, taken into the conſtitution (if we had ſuch), and paſſing off by the urine, might act upon the urethra in their paſſage through it. The balſams and turpentines paſs off in this way, and become ſpecifics for many irritations in the urinary paſſages; but how far medicines which have the power of affecting particular parts when ſound, or when under diſeaſes peculiar to thoſe parts, have alſo the powers of affecting a ſpecific irritation in them, Mr. Hunter was uncertain. He conceived, however, that they might be capable of removing any attending irritation, though not the ſpecific one. He thought, that diuretics did good inaſmuch as they increaſed the quantity of urine; but he believed ſimple water was beſt for this purpoſe, or water joined with ſuch things as encourage the patient to drink a good deal, as with tea, capillaire, orgeate, &c.

Aſtringents have frequently been preſcribed, though without the approbation of the generality of regular practitioners. It was Mr. Hunter's opinion, that ſuch medicines did not leſſen the inflammation, but that they often leſſened the diſcharge.

With regard to local applications, they may be either internal to the urethra, or external to the penis. In many caſes both kinds are proper. One would ſuppoſe, that what is applied to the urethra, muſt be the moſt likely to effect a cure, by coming immediately into contact with the diſeaſed parts.

Local applications to the urethra may be either in a ſolid or fluid form, each of which has its advantages and diſadvantages. A fluid, (ſays Mr. Hunter) is only a temporary application, and that of very ſhort duration.

The ſolid applications may remain a long time, and, in this reſpect, would ſeem to be better than fluid ones; but in general they create irritation. They muſt be uſed in the form of a bougie, which Mr. Hunter imagined was commonly injurious, when the parts were in an inflamed ſtate, though he confeſſes, that he never ſaw any harm from it in any caſe, when employed with caution.

Fluid applications to the inſide of the urethra are uſually called injections, and, like the internal remedies, are without number. However, as the inflammation is frequently removed under the uſe of injections of various kinds, have we not, (as Mr. Hunter notices) a ſtrong corroborating circumſtance in favour of an opinion, that every ſuch complaint will in time cure itſelf? This eminent ſurgeon thought, however, that practice evinced, that an injection often has almoſt an immediate effect upon the ſymptoms, and, therefore, that it muſt have ſome powers, though the injection, which would have the greateſt ſpecific effect, he believed, was not yet known. If an injection has no ſpecific powers, it muſt be very uncertain in its effects, and can only be of ſervice as far as it may be adapted to a peculiarity of conſtitution, or parts. As injections are only temporary applications, it becomes neceſſary to uſe them often, eſpecially in caſes where they are found to be of ſervice. They ſhould therefore be applied as often as convenient, perhaps every hour, or even oftener; but Mr. Hunter adds, that this muſt be regulated in ſome meaſure by the kind of injection; for, if it be irritating, it will not be proper to uſe it ſo often, as it may be productive of bad conſequences.

The ſame author obſerves, that many injections remove the ſymptoms immediately, or ſoon after the application, and prevent the formation of matter, which has given riſe to the notion of their ſhutting up the diſeaſe and driving it into the conſtitution; but this ſuppoſition cannot be true, ſince the matter is the only ſubſtance in which the poiſon is contained, and the formation of the poiſon is inſeparable from the formation of matter. Therefore, if we can prevent the one, the other cannot take place, and, of courſe, there can be no room for abſorption; ſo that there can neither be any power of infecting the conſtitution in the ſame perſon, nor of communicating the infection to others.

Mr. Hunter divided injections into four kinds, namely, the irritating, ſedative, emollient, and aſtringent. He believed that we are not acquainted with any ſpecific one, although a mercurial injection, of ſome ſort or another, is frequently fancied to have ſuch a quality.

All irritating injections act upon the principle of producing an irritation of another kind, which ought to be greater than that of the gonorrhœa, by which means the laſt is deſtroyed and the diſeaſe cured, although the pain and diſcharge may ſtill be kept up by the application.

Theſe ſymptoms will ſoon go off, as ſoon as the injection is laid aſide, becauſe they only ariſe from its irritating qualities. In this way bougies, as well as many injections, may be ſuppoſed to perform a cure; and although they increaſe the ſymptoms for a time, they never can increaſe the diſeaſe itſelf, any more (ſays Mr. Hunter) than the ſame injection, which would produce the ſame ſymptoms, if applied to the urethra of a ſound man, can communicate the diſeaſe. Moſt of the irritating injections have an aſtringent effect, and, when mild, prove ſimply aſtringents; their irritating quality depending chiefly upon their ſtrength.

Mr. Hunter was not able to determine abſolutely the kind of caſes in which irritating injections might be uſed with advantage. He thought, however, that ſuch applications ſhould never be uſed when there is already much inflammation, eſpecially in conſtitutions which cannot bear a great deal of irritation, as a previous knowledge of the diſeaſe in the ſame perſon ſometimes teaches us. Neither ſhould theſe injections be uſed when the irritation has ſpread beyond the ſpecific diſtance; when the teſticles are tender, or when they have become ſore upon a ſudden diminution of the diſcharge; when the perinæum is very ſuſceptible of inflammation, and particularly if it ſhould have formerly ſuppurated. Irritating injections alſo ought not to be employed when there is a tendency in the bladder to irritation, which is known from the patient having had, for ſome time, a frequency in making water. In all the preceding caſes they do no good, and often do miſchief: Mr. Hunter thought he had ſeen abſceſſes in the perinæum brought on by their employment.

In mild caſes, and in conſtitutions which are not irritable, ſuch injections often ſucceed, and remove the diſeaſe almoſt immediately. The practice, however, as the foregoing writer remarks, ought to be attempted with caution, and not, perhaps, till milder methods have failed. Two grains of corroſive ſublimate (hydrargyrus muriatus), diſſolved in eight ounces of diſtilled water, are an eligible injection of this kind; but an injection of only half this ſtrength may be uſed, when it is not the deſign to attempt a very ſudden cure. If, however, the injection thus weakened ſhould give conſiderable pain, or occaſion a great increaſe of ſoreneſs in making water, it muſt be ſtill more diluted.

Sedative injections, according to Mr. Hunter, will always be of ſervice in caſes where the inflammation is conſiderable, not by leſſening the diſeaſe itſelf, but by leſſening the diſeaſed action, which always allows the natural actions of the part more readily to take place. They are likewiſe very uſeful in relieving the painful feelings of the patient. Perhaps, ſays this celebrated ſurgeon, the beſt ſedative which we have is opium, as when given by the mouth or anus, as when applied to the part affected in the form of an injection. But even opium will not agree, nor act as a ſedative in all conſtitutions or parts. On the contrary, it has often oppoſite effects, producing great irritability. Lead may be reckoned a ſedative, ſo far as it abates inflammation, while, at the ſame time, it may act as a gentle aſtringent. Fourteen grains of ſaccharum ſaturni (acetite of lead), diſſolved in eight ounces of diſtilled water, make a good ſedative aſtringent injection.

Mr. Hunter next remarks, that the drinking freely of diluting liquors may, perhaps, be conſidered as having a ſedative effect, as it in part removes ſome of the cauſes of irritation, rendering the urine leſs ſtimulating, either to the bladder, when the irritation is there, or to the urethra in its paſſage through it; and the plan may poſſibly leſſen the ſuſceptibility of irritation. The vegetable mucilages of certain ſeeds and plants, and the emollient genus, are recommended for impregnating the patient's drink. Such ſubſtances paſs off with the urine, and render the evacuation of that fluid leſs painful. It is proper to notice, however, that Mr. Hunter does not appear to have a high opinion of the utility of this practice.

When the inflammation is very great, Mr. Hunter believed, that emollient injections are the moſt proper applications. It ſeems probable, that they act firſt by ſimply waſhing away the matter, and then leaving a ſoft application to the part, in which way, ſays this eminent writer, they can be of ſingular ſervice by leſſening the irritating effects of the urine. A ſolution of gum arabic, milk and water, or ſweet oil, will frequently leſſen the pain and other ſymptoms, when the more active injections have done nothing, or ſeemed to do harm.

When great irritation and ſoreneſs prevail at the mouth of the urethra, the point of the ſyringe cannot be introduced, and no attempt to uſe an injection ought to be made before the inflammation abates. Emollients may be uſed externally in the form of fomentation.

The aſtringent injections, obſerves Mr. Hunter, can only act by leſſening the diſcharge. They can have no ſpecific effect upon the inflammation. They ſhould only be uſed towards the latter end of the diſeaſe, when it has become mild and the parts begin to itch. However, if the diſeaſe ſhould begin mildly, they may be uſed at the very beginning; for, by gradually leſſening the diſcharge, without increaſing the inflammation, we complete the cure, and prevent a continuation of the diſcharge called gleet. If the aſtringent injections be ſtrong, they will be irritating, and frequently increaſe the diſcharge, inſtead of diminiſhing it. When weaker, they often ſtop the running, without haſtening, however, the cure in all caſes; for the inflammation may ſtill continue even longer than it would have done, had the tendency to ſecretion not been removed. But ſometimes an aſtringent injection will cure a ſlight irritation in a very few days. Mr. Hunter never found one aſtringent more efficacious than another. The aſtringent genus, as dragon's blood, the balſams, and the turpentines, diſſolved in water; the juices of many vegetables, as oak bark, Peruvian bark, tormentil root, and, perhaps, all the metallic ſalts, as green, blue, and white vitriols; the ſalts of mercury, and alſo alum; probably all act much in the ſame way. Mr. Hunter, however, owns that they do not act equally well in every gonorrhœa,

norrhœa, and that changing the injection will often ſucceed, when a long perſeverance in a previous one would not.

We have to obſerve, that the aſtringent injection, which is moſt generally approved of by practitioners, is that containing white vitriol (zincum vitriolatum), about half a ſcruple of which, diſſolved in eight ounces of water, is a very good application to begin with. The ſtrength may be increaſed or diminiſhed, however, as the patient's feelings may require.

Poultices and fomentations have been uſed as external applications in caſes of gonorrhœa; but, ſays Mr. Hunter, they can be of little ſervice, except when the prepuce, glans, and orifice of the urethra are inflamed. It is now more common, in the inflammatory ſtage of the complaint, to ſurround the penis with linen kept continually wet with the ſaturnine lotion.

When any of the glands of the urethra remain in an indurated ſtate, after the ſubſidence of the inflammation, the hardneſs may be removed by frictions with camphorated mercurial ointment.

It is remarked by Mr. Hunter, that in women, the mode of curing the gonorrhœa is nearly the ſame as in men; but the diſeaſe itſelf is milder, and the ſecondary ſymptoms leſs numerous in females. Hence the cure is more ſimple.

When the diſeaſe is confined to the vagina, it may be eaſily cured by means of injections, taking care alſo to waſh the external parts with the application. The patient cannot, however, apply an injection to the meatus urinarius, when that paſſage is affected.

The ſame kinds of injections are proper for women as are preſcribed for men; but they may be made doubly ſtrong, as the parts in women are not nearly ſo irritable as the common ſeat of this diſeaſe in the other ſex.

When the inflammation runs along the ducts of the glands, either of the mouth of the vagina, or of the urethra, or where it affects the glands themſelves, the caſe claims the ſame treatment as in men. The mercurial ointment ſhould be freely applied to the indurated parts. When the ducts and glands ſuppurate and form abſceſſes, theſe ſhould be opened and dreſſed like a ſore. The ulcer, however, is not regarded as venereal. Though Mr. Hunter entertained ſuch a ſentiment, and directed a correſponding treatment.

In plethoric conſtitutions, the ſymptoms are frequently violent, attended with a ſtrong propenſity to the inflammatory fever. The inflammation, however, does not extend beyond the ſpecific diſtance. Many medicines, which might be of ſervice in another conſtitution, here do harm, and increaſe the ſymptoms which they were intended to relieve. Mr. Hunter has ſeen opiate glyſters, after at firſt doing good, bring on fever and an exaſperation of all the ſymptoms. He has ſeen the balſam capivi render the inflammation worſe. The treatment of ſuch a conſtitution, when affected with this diſeaſe, ſhould chiefly conſiſt in bleeding and gentle purging. It is proper alſo for the patient to live ſparingly, and uſe little exerciſe.

In the weak and irritable conſtitution, as Mr. Hunter obſerves, the ſymptoms are frequently very violent; and often extend beyond the ſpecific diſtance, the inflammation running along the urethra, and even affecting the bladder. In this inſtance the foregoing author was of opinion, that a ſtrengthening plan ſhould be adopted.

Sometimes a gonorrhœa is ſo capricious in its cure, that the acceſſion of an accidental fever ſtops the diſcharge, removes the pain in making water, and the diſorder is permanently cured. Sometimes the ſymptoms ceaſe on the commencement of the fever, and return when the latter complaint is well. In other examples a gonorrhœa may begin mildly; but a ſevere fever coming on and continuing for ſeveral days, the ſymptoms of the firſt diſorder are rendered much worſe, and, on the fever going off, the gonorrhœa likewiſe diſappears. Mr. Hunter remarks, that although a fever does not always cure a gonorrhœa, yet, as it poſſibly may, nothing ſhould be done while the fever laſts; and if the local complaint ſhould continue after the fever is gone, it is then to be treated according to the ſymptoms.

The ſame writer repreſents, that, unfortunately, there are caſes in which no known method leſſens the ſymptoms; evacuations, a ſtrengthening plan, ſedatives and emollients, all prove uſeleſs, and time alone ſeems to bring about the cure. In theſe inſtances, Mr. Hunter thought the ſoothing plan of treatment the moſt adviſable, and was againſt the employment of aſtringents. Neither had he much opinion of the capivi and Canada balſams, nor of turpentines in general, though they might diminiſh the diſcharge.

A gonorrhœa is alſo conſiderably affected by the patient's way of life, during the inflammatory ſtate. Moſt things which hurry or increaſe the circulation, aggravate the ſymptoms, ſuch as violent exerciſe, drinking ſtrong liquors, eating ſtrong indigeſtible food, taking peppers, ſpices, ſpirits, &c.

When the complaint begins mildly, or after the violent ſymptoms have ſubſided, we may preſcribe medicines which will aſſiſt the above local remedies, in checking the diſcharge. Mr. Hunter thought the turpentines the moſt efficacious. Cantharides, cuprum vitriolatum, acetite of lead, and alum, have alſo been recommended.

The reader is already aware, that Mr. Hunter regarded gonorrhœa as a diſeaſe ariſing from the venereal poiſon, and believed that the matter from the urethra, if introduced into the circulation, would occaſion a lues venerea. In order to guard againſt the effects of abſorption, he was an advocate for exhibiting ſmall doſes of mercury at an early period of the malady, and for continuing them even for ſome time after the formation of matter is at an end. He adviſed a grain of the hydrargyrus calcinatus to be taken every night, or every evening and morning; but frictions, with the mercurial ointment, when mercury diſagreed with the ſtomach and bowels. Many practitioners at this day are ſtrongly attached to the ſyſtem of preſcribing a grain or two of calomel every day during the treatment of a gonorrhœa, and deem it unſafe to abſtain altogether from the uſe of mercury, in ſome form or another. Others give calomel with a view of its acting as an alterative and purgative. We never have ſeen any reaſon, however, for exhibiting either the hydrargyrus calcinatus, or calomel, or for employing mercury in any mode whatſoever.

Before cloſing the preſent article, it only remains for us to ſay a few words reſpecting ſome complaints, which are occaſionally attendant on gonorrhœa.

When the inflammation is violent, or ſpreads along the urethra, there is frequently a diſcharge of blood from the veſſels of that part. Mr. Hunter ſtates, that in ſuch caſes the balſam capivi has been found ſerviceable; but that he did not obſerve any good reſult from the uſe of aſtringent injections.

Opium alone, or joined with camphor, is the beſt medicine for the prevention of painful erections. Cicuta is alſo ſaid to prove uſeful for the ſame purpoſe.

With regard to the treatment of chordee, Mr. Hunter remarks, that in the beginning of this complaint bleeding from the arm is often of ſervice, but that it is more immediately uſeful to take away blood from the part itſelf by leeches. Great benefit often follows the accidental burſting of a veſſel, and a profuſe hemorrhage. Relief is often obtained

tained from expoſing the penis to the ſteam of warm water. Poultices and fomentations, eſpecially ſuch as contain camphor, are frequently productive of benefit by removing the inflammation. Opium given internally is of ſingular ſervice, and is ſtill more beneficial when joined with camphor. It leſſens the pain and prevents erections, which are the immediate cauſe of the complaint.

When the chordee continues after all the other ſymptoms are gone, the only remaining object is to promote the abſorption of the extravaſated coagulable lymph, by friction with mercurial ointment on the parts. Mr. Hunter informs us, that in one caſe conſiderable benefit ſeemed to reſult from giving cicuta, after the common methods had failed. Electricity, he ſays, may alſo be of ſervice. A chordee is often longer in diſappearing than either the running or pain; but, like moſt of the conſequences of inflammation, its declenſion is gradual and uniform.

Mr. Hunter has ſeen the kind of chordee, which ſeems to depend on ſpaſm, relieved by bark.

When the glands of the urethra ſuppurate, Mr. Hunter adviſes the uſe of mercury, juſt as if the caſe were a chancre; but this practice is not deemed neceſſary by the moſt judicious ſurgeons of the preſent day. It is proper to make an early opening into the abſceſs, when Cowper's glands ſuppurate, in order to prevent the matter from making its way into the urethra or ſcrotum.

When the bladder is affected with irritation, in conſequence of gonorrhœa, opiate clyſters, the warm bath, and copious bleeding, are the chief means of relief. Leeches applied to the perinæum have alſo good effects. Bleeding, however, in certain conſtitutions, is hurtful, and ſhould always be reſorted to with caution. When the complaint laſts very long, reſiſting ordinary methods, Mr. Hunter ſuggeſts the trial of an opiate plaſter on the pubes, or ſmall of the back; or a ſmall bliſter on the perinæum.

The mode of treating a ſwelling of the teſticle, we ſhall conſider under the head, HERNIA *Humoralis*.

The decline of a gonorrhœa is generally known by the pain becoming leſs, or changing into an itching, ſimilar to what is often felt in the beginning of the complaint, and which at length goes away altogether. The ſenſe of wearineſs about the loins, hips, teſticles, and ſcrotum is no longer felt; and the cherry-like appearance of the glans penis gradually ſubſides. The running diminiſhes, or at all events becomes whiter, then paler, and by degrees aſſumes a more ſlimy conſiſtence, in proportion as it becomes more like the natural ſecretion, which is deſigned to lubricate the urethra.

Recurrences of the diſeaſe every now and then are met with, after the pain, diſcharge, &c. have quite ceaſed. Such relapſes, however, are more common in women than men, and the complaint is uſually in a milder form than before.

GONRA, in *Geography*, a town of Hindooſtan, in Bundelcund; 20 miles N. of Callinger.

GONS, a town of Hungary; 22 miles S.S.W. of Zatmar.

GONSALVO, HERNANDEZ DE CORDOVA, in *Biography*, an eminent Spaniſh commander, was born in 1443, and brought up from a very early age to the profeſſion of arms. He ſignalized himſelf in a war againſt Portugal, and under the reign of the celebrated Ferdinand and Iſabella he ſerved in the conqueſt of Grenada. He was afterwards employed to ſuccour Ferdinand king of Naples againſt Charles VIII. of France, and by his aſſiſtance the whole of that kingdom was recovered from the French. Kings, however, are not always conſiſtent in their projects, and the monarch of Spain who had defended and ſaved one king of Naples, formed a project of ſupplanting his ſucceſſor, and making a partition of the country with Lewis XII. of France, and Gonſalvo was employed to execute the attempt. The warrior was completely ſucceſsful, and made Alphonſo, ſon of the king of Naples, his captive. Elated with his ſucceſs, and willing to ſhew his moderation, Gonſalvo ſwore upon the holy ſacrament, a wretched abuſe of a religions rite, that the young prince ſhould enjoy his liberty; but after the ſurrender was complete, and the time was come when he could execute his promiſe, he pretended that he had received new orders from his own ſovereign, which obliged him to ſend Alphonſo a priſoner into Spain. The partitioning powers ſoon diſagreed among themſelves, and the French, being in a greater ſtate of preparation, attacked, defeated, and expelled the Spaniards from moſt of the places which they poſſeſſed. Gonſalvo was now compelled to retire with his army, deſtitute of money, proviſions, and ammunition. He retired, however, only to recruit himſelf, which he had an opportunity of doing among the Venetians, when he rallied, drove the French before him, and entered Naples in triumph. Ferdinand, in the mean time, doubtful of the event, had negociated a treaty with Lewis, confirming their former partition; but upon the intelligence of the great ſucceſs of Gonſalvo, ſuch was "Spaniſh honour," that he refuſed to ſign it, and the French were, by the efforts of Gonſalvo, obliged entirely to evacuate the kingdom of Naples. For theſe and other eminent ſervices, he not only obtained the title of the "Great Captain," but was rewarded by his ſovereign with many valuable as well as honourable poſts of honour. He was made conſtable of the kingdom of Naples, raiſed to the dukedoms of Terranova, St. Angelo, and other eſtates. He at length fell under the ſuſpicion of his ſovereign, who ſent letters to recal him, which the general repeatedly eluded upon different pretexts. The king determined to go to Naples, and was met at Genoa by Gonſalvo. They entered Naples together in apparent harmony, and the king conferred an additional dukedom on his "Great Captain," but Ferdinand thought it prudent, in the following year, when he left Naples, to take his general with him. At Savona they had an interview with Lewis XII. who ſhewed his eſteem for Gonſalvo, by decorating him with a gold chain taken from his own neck, and cauſing him to ſup at the ſame table with himſelf. At Venice alſo he received ſome magnificent preſents. On his arrival in Spain, he was commanded to retire to his own eſtate at Grenada, where he died in 1515, at the age of ſeventy-two. Gonſalvo is diſtinguiſhed as a firm diſciplinarian, a great maſter of the art of war, but as one who was never diſtinguiſhed for generoſity of ſentiment. Univer. Hiſt. Moreri.

GONSALVO, *St.*, in *Geography*, a town of Brazil, in the government of St. Salvador; 40 miles W. of Sergipe.

GONTAPILLY, a town of Hindooſtan, in the circar of Cicacole; 25 miles S. of Coſſimcotta

GONUS, in *Botany*, from γονος, *offspring*, becauſe of its plentiful produce. Lour. Cochinch. 658.—Claſs and order, *Polygamia Diœcia*, Loureiro: rather *Tetrandria Tetragynia*. Nat. Ord. *Terebintaceæ*, Juſſ.?

By Loureiro's deſcription of his only ſpecies, *G. amariſſimus*, a ſhrub with pinnated ſerrated hairy leaves, and by his reference to Rumph. Amboin. Append. t. 15, it ſhould ſeem to be allied to *Fagara*, though the deſcription of the piſtil and fruit does not exactly anſwer. It agrees perhaps beſt with *Brucea*, Juſſ. 373, both in botanical characters and medical properties; ſee that article. Loureiro ſays his plant is found in the woods of China and Cochinchina, and that the virtues of the root and fruit are diaphoretic, alexiteric, antifebrile, and anthelmintic. He adds, that "it ſeems to be the ſame drug which the Portugueſe call *radix de Solor*, becauſe it grows in the iſland of Solora, as well as in Timor, and which is in great uſe in India." Is the *Brucea*, after all, an Indian plant?

GONWA, in *Geography*, a town of Hindooſtan, in Guzerat; 20 miles N.W. of Amood.

GONYALGIA, of γονυ, *knee*, αλγος, *pain*, a term uſed by ſome authors to expreſs a violent pain in the knee.

GONZAGA, Lucretia, in *Biography*, daughter of Pirro Gonzaga, lord of Gazzuolo, was diſtinguiſhed as a literary lady in the ſixteenth century. The celebrated Bandello was one of her maſters; by him ſhe was introduced to the knowledge of the Greek tragedians. She married, at the age of fourteen, Gianpaola Manfroni of Ferrara, which proved an unfortunate union, ſince her huſband, on account of a plot againſt the life of duke Hercules II. was capitally condemned in 1546. The duke did not cauſe the ſentence to be executed, but was contented with keeping him in perpetual impriſonment, under which he died in 1552. His faithful ſpouſe, Lucretia, employed all her powers to obtain his liberation: ſhe is ſaid to have addreſſed letters to almoſt all the powers in Europe, imploring their interceſſion, and one to the grand ſeignior, inſtigating him to make an attack upon the fortreſs where her huſband was confined. It muſt be obſerved, that theſe letters have been imputed to Ortenſia Landi; it cannot, however, be doubted, that this lady had acquired a conſiderable literary reputation by being ſuppoſed capable of ſuch productions. She was, indeed, panegyriſed by moſt of the learned in Italy in her time, among the reſt by Julius Cæſar Scaliger, and a volume of poems in her praiſe was publiſhed in Bologna in 1565. Several of her works were printed, one of which was a ſmall volume of poems. She remained ſingle after the death of her huſband, and placed her two daughters in a convent. She died at Mantua in 1576. Moreri.

Gonzaga, Scipio, born in 1542, was ſon of Charles, count of St. Martino, of the branch of the Gonzagas, dukes of Sabbionetta. He was carefully inſtructed in letters, and ſent to Padua to complete his ſtudies, where he greatly diſtinguiſhed himſelf in claſſical literature. He afterwards acquired conſiderable reputation for his knowledge in theology and philoſophy. Muretus, in 1571, dedicated to him the firſt volume of his Orations, with a high panegyric: and Guarini ſubmitted to his criticiſm his "Paſtor Fido." He was created cardinal in 1587, and died at Samartino in the year 1593, leaving behind him commentaries of his own life, written in elegant Latin. Moreri.

Gonzaga, Vespasian, duke of Sabbionetta, born in 1531, is celebrated as a commander in the ſervice of Charles V. and Philip II., but he is ſtill more diſtinguiſhed as a ſplendid promoter of the arts and ſciences. He built from the ground the city of Sabbionetta, which, for the neatneſs and regularity of the ſtreets, the architecture of the private houſes, the beauty of the churches, and the elegance of the public buildings, has excited univerſal admiration. He alſo founded in it a public ſchool for the learned languages, to which he invited as a profeſſor Mario Nizzoli, one of the moſt learned men of the age. His palace was always full of men of knowledge and ſcience, of whom he was the liberal patron. Gonzaga employed Scammozi in the erection of a very fine theatre, for the performance of dramatic pieces, and he is himſelf recorded as an elegant Italian poet. He is mentioned with high reſpect and applauſe by Taſſo, and other literary characters, and he is noticed as a collector of books.

Gonzaga, in *Geography*, a town of Italy, in the department of the Mincio; 16 miles S. of Mantua.

GONZAGO, St., a town of Peru, in the audience of Quito; 60 miles N.W. of St. Joſef de Huales.

GONZALES, Bartolome, in *Biography*, a painter, born at Valladolid in the year 1564. He frequented the ſchool of Patricio Caxes at Madrid; in the ſequel painted much for Philip III. at Burgos, Valladolid, Lerma, in the Pardo and Eſcurial, till 1617, when he was made painter to the court, in the place of Fabricio Caſtello. His portraits are admirable, eſpecially the ſix whole lengths with the date 1621, poſſeſſed by the baron of Caſa Davalillo. In hiſtory, his ſtyle was ornamental; his drapery, a varied imitation of ſtuffs, by its illuſion captivated the vulgar, whilſt it deſtroyed the dignity, ſimplicity, and generally the coſtume of the ſubject. He died in 1627, not, as Palomino ſtates, in 1611. Fuſeli's Pilkington.

GOOBER, in *Geography*, a country of Africa, S. of Wangara, between 10° and 12° N. lat. and 15° and 20° E. long. The mountains of Komri, ſo called by Abulfeda, commence in this territory.

GOOCHLAND, a county of Virginia, in America, ſurrounded by Louiſa, Flavanna, Henrico, Hanover, and Powhatan counties; about 40 miles long and 14 broad, and containing 4893 free inhabitants, and 4803 ſlaves.

GOOD, or Goodneſs, denotes whatever tends or conduces to preſerve or improve human nature or ſociety; in oppoſition to *evil*, which tends to deſtroy, injure, or impair the ſame.

Hence good is divided by the philoſophers into 1. *Bonum ſui*, private good; which is that whereby a thing tends to preſerve, &c. itſelf, under which comes that popular diviſion of goods of body, mind, and fortune.

2. *Bonum communionis*, whatever promotes the intereſt and welfare of ſociety; as all the civil offices, &c.

Good, in *Metaphyſics*, or *Metaphyſical Good*, called alſo *abſolute* or *real* good, and *good per ſe*, is the eſſential perfection or integrity of a thing whereby it has every thing that belongs to its nature.

In this ſenſe, all things are good, inaſmuch as they have the perfections naturally belonging to things of their kind. Thus, a thinking ſubſtance is good, or perfect, as it has all the eſſential attributes of thought; ſo an extended ſubſtance is good, as it poſſeſſes all the parts neceſſary to conſtitute it ſuch.

In effect, as it is abſurd to imagine a being without its eſſence, ſo is it to imagine a being without the requiſites of its eſſence: ſo that it appears an error in ſome philoſophers, who divided beings into good or perfect, and evil or imperfect. See Essence.

Others define metaphyſical, or tranſcendental goodneſs, by congruency with the divine will, which, they ſay, conſtitutes the meaſure of all real goodneſs.

Good, *Phyſical* or *Natural*, is that whereby a thing poſſeſſes all things neceſſary to its *bene eſſe*, *i. e.* its well being, or ſecond perfection, and to the performance of its functions and uſes.

In this ſenſe, phyſical goodneſs coincides with phyſical perfection.

To this are required the ſeveral powers and faculties, in their proper degree; a due ſituation, figure, and proportion of parts, &c.

Note, beſide abſolute phyſical goodneſs, there may be a *relative* one; as in foods, which to one, are ſalutary, to another poiſon, &c. To this head alſo belong the things good *pro tempore*, or according to circumſtances; as the amputation of a mortified limb, &c.

Natural good may be otherwiſe defined to be that which makes or denominates a being happy, or prepares him for happineſs; or, at leaſt, prevents or removes his miſery: accordingly, good is either objective or formal; *objective* good is that which makes us happy; *formal* good, or the pleaſure reſulting from the application of the faculty to the object, is that which denominates us happy.

Good, *Moral* or *Ethical*, is the agreement of a thinking, reaſonable being, and of the habits, acts, and inclinations of ſuch a being with the dictates of right reaſon, and the will of the Creator, as diſcovered by natural light. See Virtue.

In order to this, it is not enough that a thing done, ſaid, thought, deſired, be juſt and good; but it muſt be done, thought, &c. well, *i. e.* from good principles, and to good ends.

Others define moral good more largely. *Moral*, which they alſo call *relative* good, according to them, is ſomething that is good to another, or that tends ſome way to the perfection thereof. In this ſenſe they divide it into three kinds, *honeſtum*, *jucundum*, and *utile*.

The firſt, *bonum honeſtum*, is what agrees with right reaſon, and is deſirable for itſelf; as all things virtuous; *e. gr.* to love God, reſpect our parents, &c. It is conſidered without any regard to pleaſure; not but there is ſincere pleaſure annexed to it. Zeno and the Stoics allow of no other goods; thoſe of the body, &c. they call *commoda*, *conveniences*, not goods.

Bonum jucundum is that which is good, as it tends to give us pleaſure, and is deſired on that account; but without any repugnancy to virtue or right reaſon; as muſic to the ears, painting to the eyes, &c.

Bonum utile, or *commodum*, is that which is good on account of ſomething elſe for which it is deſired; as money, riches, &c.

Good, *chief*, *ſovereign*, or *ſupreme*, *ſummum bonum*, is that, the enjoyment of which renders men truly and completely happy. The ſchools diſtinguiſh this chief good of man into that which is ſimply and adequately ſo, and beyond which there can be no other; and an inferior, ſubordinate kind, which is, in ſome meaſure, attainable in this imperfect ſtate. This laſt they call *felicitas viatorum*, and the former *felicitas comprehenſorum*. The chief or ſovereign good, according to the idea collected of it from the original, natural, and univerſal preconceptions of all mankind, is ſomething agreeable to our nature, conducive to well-being, accommodate to all places and times, durable, ſelf-derived, and indeprivable; and this conſiſts, ſays Mr. Harris, in rectitude of conduct, or in living perpetually ſelecting, as far as poſſible, what is congruous to nature, and rejecting what is contrary, making our end that ſelecting and rejecting only. Three Treatiſes, &c. 1765, p. 121, &c. 205, &c.

Philoſophers are divided as to what the chief good of man conſiſts in; whether in the goods of fortune, of body, or of mind. Some hold riches and honours the ſupreme good; others, as Ariſtippus and the Cyrenaic ſchool, bodily pleaſures; and others, as Zeno and the Stoics, virtue, or living according to nature. The Peripatetics agreed with the Stoics in maintaining that virtue is the *ſummum bonum*: but the Stoics aſſerted farther, that virtue was the only good: whilſt the Peripatetics denied, with reaſon, that virtue was ſelf-ſufficient, and therefore required ſeveral other things as auxiliaries, ſuch as health, proſperity, friends, &c. which are to the virtuous man in the nature of inſtruments or ornaments to his felicity. An excellent writer lays down the following *criteria* or characteriſtics of the *ſummum bonum*, or chief good, which reaſon can demonſtrate to be actually deſigned for man: it is ſomething which all men, if not wanting to themſelves, may be poſſeſſed of; it is one and the ſame to all mankind; and while in itſelf fitted to make the poſſeſſor happy, is not prevented in its operation by ſome other thing which keeps him from reliſhing it: and as to the higheſt good which it is poſſible for man to enjoy, it muſt be referred to no other, but all others muſt be embraced for the ſake of this; and it muſt be ſufficient to furniſh a happineſs adequate to the capacities of human nature, and of equal duration; *i. e.* it muſt be not only perfect whilſt it laſts, but everlaſting. According to theſe characters we may infer, that neither the goods of fortune, nor thoſe of the body, nor even virtue itſelf, conſtitute the chief good. Virtue, rightly underſtood, is the perfection of human nature; it is the inſtrument of obtaining happineſs: but this alone will not make a man happy; it is farther neceſſary that he be perfect as to life, or happy in the circumſtances of his being: and, therefore, natural reaſon demonſtrates, that the favour of God, ſecured by virtue, is properly man's ſupreme good. Grove's Syſtem of Moral Philoſophy, vol. i. part. 1. paſſim. See Epicureans, Peripatetics, and Stoics.

Good-*will*. See Benevolence.

Good *Works*. See Merit and Supererogation.

Good *Abearing*, *bonus geſtus*, in a *Law Senſe*, is particularly uſed for an exact carriage or behaviour of a ſubject towards the king and his liege people; to which ſome men, upon their miſbehaviour, are bound.

The juſtices are empowered by 34 Edw. III. cap. 1. to bind in this manner all them that be not of good fame; under which general expreſſion, it is holden that a man may be bound to his good behaviour for cauſes of ſcandal, *contra bonos mores*, as well as *contra pacem*; as, for haunting bawdy-houſes; for keeping bad women in his own houſe; or for words tending to ſcandalize the government; or in abuſe of the officers of juſtice, eſpecially in the execution of their office: a juſtice may alſo bind over all night-walkers, eaves-droppers, ſuch as keep ſuſpicious company, or are reported to be pilferers or robbers, common drunkards, whore-maſters, the putative fathers of baſtards, cheats, idle vagabonds, and any other perſons, whoſe miſbehaviour may reaſonably bring them within the general words of the ſtatute. Perſons of this deſcription may be bound, with one or more ſureties, in a recognizance or obligation to the king, entered on record, and taken in ſome court, or by ſome judicial officer, whereby the parties acknowledge themſelves to be indebted to the crown in the ſum required, *e. gr.* 100*l.* with condition to be void and of none effect, provided that they behave themſelves well, either generally or ſpecially, for the time therein limited; as for one or more years, or for life. This recognizance, if taken by a juſtice of the peace, muſt be certified to the next ſeſſions, by 3 Hen. VII. cap. 1. and if the condition of it be broken, the recognizance becomes forfeited or abſolute; and being eſtreated or extracted, (*i. e.* taken out from among the other records) and ſent up to the exchequer, the party and his ſureties are become the king's debtors, and are ſued for the ſeveral ſums in which they are bound. All perſons under the king's protection may obtain ſuch ſecurity, upon due cauſe ſhewn; and the juſtice may be compelled to grant it by a mandatory writ, called *ſupplicavit*: but this writ is ſeldom uſed, for, when application is made to the ſuperior courts, they uſually take the recognizances there, under the direction of the ſtatute 21 Jac. I. cap. 8. A recognizance may be diſcharged, either by the demiſe of the king, or by the death of the principal party bound thereby, or by order of the court to which it is certified by the juſtices. He that is bound to this, Lambard ſays, is more ſtrictly bound than to the peace; becauſe, whereas the peace is not broken without an affray, battery, or ſuch like, this ſurety *de bono geſtu* may be forfeited by the number of a man's company, or by his or their weapons or arms, by ſpeaking words tending to ſedition, or by committing any of thoſe acts of miſbehaviour which the recognizance was intended to prevent.

Good *Aller*. See Aller.

Good *Behaviour*. See Good *abearing* and Peace.

Good *Conſideration*. See Consideration.

Good *Fortune*, or Para, in *Geography*, an iſland in the Eaſt Indian ſea, near the W. coaſt of Sumatra, about 36 miles long and ſix broad. S. lat. 1° 5′. E. long. 98° 30′.

Good *Taſte*. See Taste.

GOODALORE, in *Geography*, a town of Hindooſtan, in the circar of Dindigul; 10 miles S. of Ootampaliam.

GOODENIA, in *Botany*, ſo named by the writer of the preſent article in honour of the Right Rev. Samuel Goodenough, lord biſhop of Carliſle, F.R.S. and a vice-preſident of the Linnæan Society, author of a moſt valuable paper on Britiſh *Carices*, in the ſecond volume of the Linn. Society's Tranſactions, and of one on Britiſh *Fuci*, in conjunction with Mr. Woodward, in the third. The name was conſtructed after the example of Tournefort, who, as he tells us, not without much conſideration, contrived to form *Gundelia* out of *Gundelſcheimer*. It did not occur to us at the time that *Goodenovia* might have come nearer to the original, and have been equally unexceptionable. It is now too late to make any ſuch alteration. Linnæus named *Richardia* after Dr. *Richardſon*, *Stillingia* after Mr. *Stillingfleet*, and theſe are ſufficient precedents. Sm. Tr. of Linn. Soc. v. 2. 346. Brown. Prodr. Nov. Holl. v. 1. 574. Willd. Sp. Pl. v. 1. 954. Mart. Mill. Dict v. 2. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Campanulaceæ*, Juſſ. *Goodenoviæ*, Brown.

Gen. Ch. *Cal.* Perianth ſuperior, of five, nearly equal, linear leaves, permanent. *Cor.* of one petal, much longer than the calyx, irregular; tube ſlit from top to bottom at the back; limb of five deep, firm, lanceolate ſegments, with thin dilated longitudinal borders, turned moſt to one ſide, forming one lip, or generally two. *Stam.* Filaments five, ſhorter than the tube, often projecting through its fiſſure, capillary, equal; anthers vertical, oblong, of two lobes. *Piſt.* Germen inferior, oblong, crowned with the calyx-leaves, which run down its ſides and form ribs; ſtyle taper at the baſe, ſwelling upwards, undivided, nearly as long as the tube; ſtigma large, firm, obtuſe, enveloped with a cup-ſhaped cover, more or leſs two-lipped, its margin fringed with denſe upright hairs. *Peric.* Capſule oblong or elliptical, of two valves ſeparating at the top, and two (rarely four) cells, the partition flat, parallel to the valves. *Seeds* numerous, imbricated, compreſſed.

Eſſ. Ch. Corolla of one petal, ſlit longitudinally at the back; limb in five deep ſegments turned one way. Anthers ſeparate, beardleſs. Stigma with a cup-ſhaped fringed integument. Capſule inferior, of two or four cells, with a parallel partition. Seeds numerous, imbricated.

Obſ. Mr. Brown has remarked, in ſome ſpecies, a ſmall bag of honey attached to the germen, oppoſite to the fiſſure in the corolla.

Eight ſpecies of this very curious genus were originally defined in the Linnæan Society's Tranſactions, three of which, having been deſcribed without a knowledge of their fruit, are now, on more full examination, removed by Cavanilles and Brown to other genera. Theſe are the *albida*, *ſtricta*, and *ramoſiſſima*; the latter, which, like the *albida*, is a *Scævola*, may be ſeen in Sm. Bot. of N. Holl. t. 5. The *ſtricta* belongs to Mr. Brown's *Dampiera*. But on the other hand the diſcoveries of this indefatigable collector and accurate botaniſt have increaſed *Goodenia* to 32 ſpecies, all natives of New Holland or of Van Diemen's land. Of theſe the firſt 28 have a two-lipped corolla, and the firſt 24 of them have yellow flowers, the reſt blue or purple. Of the remaining four, two have a ſingle-lipped corolla, and the others are doubtful in this reſpect, it being doubtful whether theſe laſt properly belong to the genus. One of them is *Selliera radicans*; Cavan. Ic. t. 474. f. 2. *Goodenia repens*; Billard. Nov. Holl. t. 76.

Satisfactory examples of the genus are,

G. *paniculata*. Sm. n. 2. Cavan. Ic. t. 507. This has yellow *flowers* in terminal panicles. *Leaves* moſtly radical, ſtrongly toothed. *Herbage* hairy.

G. *ovata*. Sm. n. 1. Cav. Ic. t. 506. Andr. Repoſ. t. 68. The firſt ſpecies that flowered in England, and from which the genus was deſcribed. This has rather ſhrubby *ſtems*, ovate neatly ſerrated ſmooth *leaves*, and axillary forked ſtalks, bearing elegant yellow *flowers*. It is a deſirable ornament for a greenhouſe, and not difficult of culture.

G. *grandiflora*. Sims in Curt. Mag. t. 890. Differs from the laſt in being downy, with lyrate *leaves* and larger *flowers*, whoſe tube is ſplit into four ſegments, and ſingularly rough or bearded within.

G. *elongata*. Billard. Nov. Holl. t. 75. Is a very ſlender ſpecies, with long ſimple flower-ſtalks deſtitute of bracteas.

GOODENOVIÆ, a natural order of plants recently eſtabliſhed by Mr. Brown, Prodr. Nov. Holl. v. 1. 573, being ſeparated by him from the *Campanulaceæ* of Juſſieu, and eſſentially diſtinguiſhed by a peculiar cup-ſhaped integument, either undivided or two-lobed, which contains the ſtigma, and has hitherto been deſcribed by botaniſts as the ſtigma itſelf. See Campanulaceæ.

Mr. Brown deſcribes his new order as follows:

Calyx ſuperior or half ſuperior, rarely inferior, five-cleft, ſometimes in five or three deep diviſions, ſometimes ſhort, undivided, and occaſionally obſolete; its ſegments equal, rarely unequal, permanent.

Corolla of one petal, more or leſs irregular, deciduous or withering. Tube ſplit longitudinally, ſometimes ſeparable into five portions, while the calyx is merely attached to the baſe of the germen. Limb in five deep ſegments, compoſing one lip or two, their diſk lanceolate, flat, their ſides, or wings, of a thinner texture, elevated, folded inwards when young, rarely obſolete or deficient.

Stamens five, unconnected with either corolla or ſtyle, and alternate with the diviſions of the former. Filaments diſtinct. Anthers either ſeparate or cohering, linear, vertical, attached by their baſe, undivided, two-celled, the cells opening lengthwiſe. Pollen ſimple, rarely compound.

Germen of two or four cells, rarely of one only; the rudiments of the ſeeds either indefinite or definite, erect; ſometimes bearing a gland between the two anterior filaments. Style one, ſimple, very rarely divided. Stigma fleſhy, obtuſe, either undivided or two-lobed, encompaſſed from beneath with a ſomewhat membranous, cup-ſhaped, entire or two-lobed integument, the great peculiarity of the order.

Pericarp, when the number of the ſeeds is indefinite, a capſule of two cells, rarely four, or ſometimes, from the ſhortneſs of the partition, of ſcarcely more than one. Partition moſtly parallel, rarely contrary, to the valves, which are either undivided or cloven, bearing the ſeeds on its midrib. When the number of the ſeeds is definite, one being in each cell, the pericarp is a drupa or a nut, rarely an *utriculus* (or membranous undividing capſule), bearing the ſeed from its baſe.

Seeds often with a thickiſh coat, ſometimes with a hard ſhell. Albumen fleſhy, ſhaped like the ſeed, ſeldom wanting.

Embryo ſtraight, about as long as the albumen. Cotyledons of a middling ſize, often leafy. Plumula inconſpicuous.

Theſe plants are either herbaceous or ſhrubby, not milky, chiefly found in the ſouthern hemiſphere, rarely within the northern tropic. Their pubeſcence when preſent is generally ſimple, ſometimes glandular, rarely ſtellated. Leaves ſcattered, without ſtipulas, ſimple, moſtly undivided, ſometimes lobed, often toothed. Infloreſcence terminal or axillary, various. Flowers diſtinct, very rarely aggregate, yellow, blue or purpliſh, ſeldom reddiſh.

The firſt ſection, with indefinite ſeeds, contains ſix genera; *Goodenia*, *Calogyne*, *Euthales*, *Velleia* of Smith, *Lechenaultia* and *Anthotium:* the ſecond, with definite ſeeds, three genera; *Scævola* of Linnæus, much augmented, *Diaſpaſis* and *Dampiera:* the third ſection, with a ſingle-ſeeded *utriculus*, is contrived to admit the *Brunonia*, named after the worthy and intelligent author, by Dr. Smith in the 10th volume of the Linnæan Society's Tranſactions not yet publiſhed. The place of this genus in a natural ſeries is extremely difficult to determine. It agrees with the *Goodenoviæ* chiefly in having an integument to the ſtigma, but in habit, aggregate flowers, four diſtinct bracteas, and ſome other marks, agrees with the *Dipſaceæ* of Juſſieu, to which it is referred, not without doubt, in the Linnæan Tranſactions. It conſiſts of two ſpecies, *Brunonia ſericea*, and *auſtralis*, herbaceous plants, with the aſpect of ſimple-leaved *Scabioſæ*.

GOODEROE, in *Geography*, a town of Abyſſinia; 94 miles S.S.E. of Miné.

GOOD HOPE, or HOPE ISLAND, an iſland in the S. Pacific ocean, diſcovered by Le Maire and Schooten in 1616. The land is mountainous, not very high, and abounds with cocoa-nut trees; the coaſt affords no anchorage. S. lat. 16°. E. long. 174° 15'.—Alſo, the name of a Daniſh colony in Weſt Greenland. N. lat. 64°.

GOOD HOPE, *Cape of*. See CAPE.

GOODIA, in *Botany*, in memory of Mr. Peter Good, an induſtrious gardener, employed in collecting ſeeds in New South Wales for the Kew garden. He died, ſome years ſince, in that remote country, and Mr. Brown has always been ſo ſenſible of his merits, that he has long deſtined a genus to his honour.—Saliſ. Parad. Lond. t. 41. Sims. in Curt. Mag. t. 958.—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, ſomewhat bell-ſhaped; its upper lip with two, lower with three, longer and ſharper, teeth. *Cor.* papilionaceous. Standard broad, inverſely heart-ſhaped, erect. Wings horizontal, obovate, rather ſhorter. Keel nearly equal to the wings, abrupt, of two petals united in their lower part. *Stam.* Filaments ten, diadelphous, nine in one ſet, one diſtinct; anthers roundiſh. *Piſt.* Germen ſtalked, ovate, compreſſed; ſtyle awl-ſhaped, aſcending; ſtigma ſimple, obtuſe. *Peric.* Legume ſtalked, ovate, compreſſed, of one cell, gibbous and flat at the back. *Seeds* two, roundiſh, compreſſed.

Eſſ. Ch. Calyx two-lipped; the upper cloven, broadeſt and ſhorteſt. Legume ſtalked, compreſſed, flat at the upper edge, of one cell. Seeds two.

Obſ. This genus, as Dr. Sims obſerves, ought to be placed next to *Boſſiæa*, Tr. of Linn. Soc. v. 9. 302, from which it differs eſſentially in its legume, which has no dilated thickened edges, nor is it internally ſpongy nor many-celled. The ſtamens are truly diadelphous, in which it differs from *Crotalaria*, as alſo in not having an inflated legume, though its habit comes neareſt to that genus.

Two ſpecies are known.

1. G. *lotifolia*. Curt. Mag. t. 958.—Leaflets ſmooth, as well as the branches and flower-ſtalks.—Native of Van Diemen's land. One of the firſt New Holland plants raiſed in this country, and very hardy in the green-houſe, poſſibly able to bear our climate. Mr. Aiton favoured us with ſpecimens from Kew in 1796. It is a delicate ſmooth *ſhrub*, with ternate ſomewhat glaucous *leaves*, and terminal cluſters of numerous yellow *flowers*, the baſe of whoſe ſtandard, and part of the wings, are ſtained with crimſon, as in many New Holland flowers of this family. The *legume* is ſomewhat ovate, with a taper baſe, ſmooth, but marked with numerous, tranſverſe, parallel, reticulated veins. One *ſeed* only is uſually perfected.

2. G. *pubeſcens*. Curt. Mag. t. 1310.—Leaflets downy, as well as the branches and flower-ſtalks.—Very like the former, and brought from the ſame country. It flowered at Mr. Loddige's at Hackney. We think with Dr. Sims it has ſufficiently the aſpect of a diſtinct ſpecies, though its downineſs, often a variable circumſtance, affords the only ſpecific character. The *leaflets* in the plate do not anſwer to his definition of obcordate, and we believe they vary in ſhape, as in many leguminous plants.

GOODIANELLI, in *Geography*, a town of Hindooſtan, in Myſore; 19 miles N. of Seringapatam.

GOODIMANELLE, a town of Hindooſtan, in Myſore; 20 miles W. of Bangalore.

GOODINGARY, a town of Hindooſtan, in Tinevelly, near the coaſt; 50 miles S. of Palamcotta.

GOODLUCK BAY, a ſmall bay in the ſtrait of Magellan, entirely ſurrounded by rocks. This bay ſupplies a little wood, and plenty of good water, but it is very difficult of acceſs. S. lat. 53° 23'. W. long. 74° 33'. Variation two points eaſterly.

GOODNESS, in *Theology*, expreſſes one of the attributes of the Deity, ſometimes denominated *Benevolence*. (See ATTRIBUTES and BENEVOLENCE.) Dr. Paley, in his "Natural Theology," illuſtrates and proves the divine goodneſs by two propoſitions, which may be evinced by obſervations drawn from the appearances of nature. The *firſt* of theſe propoſitions is, that in a vaſt plurality of inſtances in which contrivance is perceived, the deſign of the contrivance is *beneficial*. No productions of nature diſplay contrivance ſo manifeſtly as the parts of animals, and all theſe parts have a real, and, with very few exceptions, a known and intelligible, ſubſerviency to the uſe of the animal. Nor is the benevolent deſign of the creator abortive. The world, made with this deſign, is a happy world. The air, the earth, the water, teem with delighted exiſtence. This argument is ſtated by the author in his "Moral Philoſophy" in the following manner; "Contrivance proves deſign; and the predominant tendency of the contrivance indicates the diſpoſition of the deſigner. The world abounds with contrivances, and all the contrivances which we are acquainted with are directed to beneficial purpoſes. Evil no doubt exiſts; but is never, that we can perceive, the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inſeparable from it; or even, if you will, let it be called a defect in the contrivance; but it is not the object of it. This is a diſtinction which well deſerves to be attended to. In deſcribing implements of huſbandry, you would hardly ſay of the ſickle, that it is made to cut the reaper's hand, though, from the conſtruction of the inſtrument, and the manner of uſing it, this miſchief often follows. But if you had occaſion to deſcribe the inſtruments of torture or execution, this engine, you would ſay, is to extend the ſinews; this to diſlocate the joints; this to break the bones; this to ſcorch the ſoles of the feet. Here pain and miſery are the very objects of the contrivance. Now, nothing of this ſort is to be found in the works of nature. We never diſcover a train of contrivance to bring about an evil purpoſe. No anatomiſt ever diſcovered a ſyſtem of organization, calculated to produce pain and diſeaſe; or in explaining the parts of the human body, ever ſaid, this is to irritate; this to inflame; this duct is to convey the gravel to the kidnies; this gland to ſecrete the humour which forms the gout; if by chance he come at a part of which he knows not the uſe, the moſt he can ſay is, that it is uſeleſs; no one ever ſuſpects that it is put there to incommode, to annoy, or to torment."

Our author's *ſecond* propoſition is, "that the Deity has added *pleaſure* to animal ſenſations, beyond what was neceſſary for any other purpoſe, or when the purpoſe, ſo far as it was neceſſary, might have been effected by the operation of pain." There is a claſs of properties, pertaining to animals, which may be ſaid to be ſuperadded from an intention expreſsly directed to happineſs; an intention to give a happy exiſtence diſtinct from the general intention of providing the means of exiſtence, with which other capacities are connected; and that is, of capacities for pleaſure, in caſes, wherein, ſo far as the conſervation of the individual, or of the ſpecies, is concerned, they were not wanted, or wherein the purpoſe might have been ſecured by the operation of pain. The proviſion which is made of a variety of objects, not neceſſary to life, and adminiſtering only to our pleaſures; and the properties given to the neceſſaries of life themſelves, by which they contribute to pleaſure as well as to preſervation; ſhew a farther deſign than that of giving exiſtence. This obſervation is illuſtrated by our ingenious author in a variety of familiar inſtances, deduced from the ſenſes of taſte, hearing, ſmell, and ſight. The ſenſes appear to be ſpecific gifts, miniſtering not only to preſervation, but to pleaſure. But the ſenſes, as they are uſually called, are far from being the only vehicle of enjoyment, or the whole of our conſtitution, which is calculated for the purpoſe. We have many internal ſenſations of the moſt agreeable kind, hardly referable to any of the five ſenſes. Beſides theſe there are exerciſes of the underſtanding in volition, &c. of the imagination, and of other faculties of the mind, which furniſh unmixed gratifications, without any counterbalancing pains. Whilſt the above-ſtated propoſitions can be maintained, we are authorized to aſcribe to the Deity the character of benevolence; and what is benevolence at all, muſt in him be *infinite* benevolence, by reaſon of the infinite, that is to ſay, the incalculably great, number of objects, upon which it is exerciſed. But beſides the evidences of divine goodneſs that are furniſhed by a ſurvey of the creation of the world, and eſpecially of mankind; the ſame attribute is evinced in the providential government of the univerſe, and in the extraordinary means which the Deity has ſelected and purſued for meliorating the preſent condition of the human race, for recovering mankind from the degeneracy and miſery that have prevailed in conſequence of their own folly and vice, and for conducting them to the perfection of knowledge and virtue, and a happy immortality in a future world.

The character and undertaking of Jeſus Chriſt, and all the benefits that reſult to mankind from his miſſion and mediation, reflect peculiar luſtre on the benevolence of the Deity.

GOODOOR, in *Geography*, a town of Hindooſtan, in Golconda; 35 miles S.E. of Warangole.—Alſo, a town of Hindooſtan, in the circar of Adoni; 15 miles N.N.E. of Condanore.

GOODS, in *Mining*, ſignify, in Derbyſhire, the large and ſizable lumps of lead ore, otherwiſe called bing or potter's ore.

Goods, among public brewers, denote the malt or grains and liquor in their maſh-tun.

Goods, *bona*, in *Law*, and particularly the *Civil Law*, include all kinds of effects, riches, lands, poſſeſſions, &c. There are two kinds of goods; *moveable*, *res moventes*, or *mobiles*; and *immoveable*, called *res non moventes*, or *immobiles*.

It is a maxim in the civil juriſprudence, that he who confiſcates the body, confiſcates the goods; meaning, that all the effects of a perſon condemned to a capital puniſhment, or perpetual baniſhment, are forfeited to the king.

A man is ſaid to bind himſelf body and goods; meaning, that beſides his goods, he obliges his perſon, and ſubmits to remain in priſon, provided he do not execute his promiſe.

Goods, again, are divided into, 1. *Proper*, *paternal*, *patrimonial*, *hereditary*; 2. *Acquired* or *acqueſts*, *alio quam hæreditatis jure acquiſita*, and, 3. *Conqueſts*, *viro & uxori ſtante ſocietate acquiſita*.

Goods, again, are divided into *real* and *perſonal*. (See CHATTELS and ESTATE.) And, laſtly, into *noble* or *free*, and *ſervile* or *baſe*.

Goods belonging to the domain of the crown, *ad fiſcum ſpectantia*, cannot be alienated for ever, unleſs it be done by way of exchange: they may be ſold under the faculty of perpetual redemption.

Goods, *Adventitious*, *adventitia*, are thoſe which ariſe otherwiſe than by ſucceſſion from father or mother, or from direct anceſtor to deſcendant. See ADVENTITIOUS.

Goods, *Dotal*, *dotalia*, thoſe accruing from a dowry, and which the huſband is not allowed to alienate. See DOWRY.

Goods, *Fugitives*. See FUGITIVE.

Goods, *Paraphernal*. See PARAPHERNALIA.

Goods, *Prohibited*. See PROHIBITED.

Goods, *Profectiticus*, *profectitia*, are thoſe ariſing by direct ſucceſſion.

Goods, *Receptitious*, were thoſe which the wife might reſerve the full property of to herſelf, and enjoy them independently of her huſband; ſo called, in diſtinction from *dotal* and *paraphernal goods*.

Goods, *Vacant*, *vacantia*, are thoſe abandoned, or left at large, either becauſe the heir renounces them, or that the defunct has no heir. See BONA.

Goods, *Allotting of*. See ALLOTTING.

Goods, *Conſignment of*. See CONSIGNMENT.

Goods, *Running of*. See RUNNING.

GOODWIN, John, in *Biography*, a learned divine in the ſeventeenth century, who is ſaid to have made more noiſe in the world than any other perſon of his age, rank, and profeſſion. He was born in 1593, and received his academical education at Queen's college, Cambridge; and, immediately after he was admitted to orders, he was much admired for the erudition and elegance which diſtinguiſhed his pulpit compoſitions. In 1633 he was inducted to the living of St. Stephen, Coleman ſtreet, London, from which he was ejected in 1645, becauſe he refuſed to baptiſe the children of his pariſhioners promiſcuouſly, and to adminiſter the ſacrament to his whole pariſh. He embraced the Arminian doctrines, and eagerly pleaded their cauſe in his ſermons and writings; he adopted and maintained the independent form of church government, and he was reckoned to be exceedingly ſkilful and courageous in attacking or repelling thoſe who oppoſed him. His tenets were not thoſe generally embraced, and at one period he is characterized as a man by himſelf; as being againſt every man, and having almoſt every man againſt him. He had a clear head, a fluent tongue, a penetrating ſpirit, and a marvellous faculty in deſcanting on ſcripture. In politics he was a decided and ſtrenuous republican, and, being eager in whatever he engaged, diſtinguiſhed himſelf by his diſcourſes and writings to promote, and afterwards to juſtify, the condemnation of the king. He lived, however, long enough to feel the weight of government directed againſt himſelf and his writings. He was obliged to abſcond for a ſeaſon, and one of his pieces was burnt by the common hangman, and in the ſame fire which executed its commiſſion on the "Defenſio pro populo Anglicano," by John Milton of immortal memory. The friends which his Arminian principles had procured him, found means to pacify the people in power, and to aſſure themſelves that Goodwin ſhould not be proſecuted for the part which he had taken in the late reign. He returned from ſolitude, and became miniſter of a private congregation in the neighbourhood of Coleman ſtreet, and, diſapproving of the act of uniformity afterwards paſſed, continued a diſſenter from the eſtabliſhed church of the Independent denomination, till his death in 1665, in the ſeventy-ſecond year of his age. His works, which are chiefly theological, are very numerous, among which the following may be mentioned; "Redemption Redeemed," in folio. "The divine Authority of the Scriptures," 4to. "An Expoſition of the ninth Chapter of the Epiſtle of St. Paul to the Romans," 4to. Neal's Hiſt. of the Puritans, &c.

Goodwin, Thomas, who is ſtyled by Anthony Wood "One of the Atlaſſes and patriarchs of independency," was born in the year 1600 at Rolesby in Norfolk. Having received the elements of a grammatical learning, he was ſent, when he was thirteen years old, to Chriſt-church college, Cambridge, where he applied himſelf with ſo much diligence to his ſtudies, as to ſecure the eſteem of his tutors, and to attract much notice in the univerſity. In 1619 he was removed to Catherine Hall, of which he became a fellow. He ſoon ſhewed a decided inclination to the views and ſentiments of thoſe who were denominated Puritans, and taking them as his models, he prepared himſelf for the office of a Chriſtian miniſter. It is not known when he took orders, but he was elected lecturer of Trinity church, in Cambridge, in the year 1628, and in 1632 he was preſented by the king to the vicarage of the ſame church. In theſe employments he was greatly admired and followed by the Puritans, who began to look up to him as a leader, but becoming diſſatisfied with the terms of conformity, he relinquiſhed his preferments, and quitted the univerſity in the year 1634. In 1639 he was ſelected as an object of perſecution by the epiſcopal conſiſtories, and to enjoy liberty of conſcience he fled to Holland, where he was choſen paſtor to an independent congregation at Arnheim. During the ſittings of the Long Parliament he returned to London and became paſtor of a church there, and alſo a member of the aſſembly of divines. His conduct, in their various meetings, and his zealous ſupport of the Preſbyterians, contributed to render him a favourite with Cromwell, through whoſe influence he was, in 1649, made one of the commiſſioners for the approbation of public preachers, and alſo appointed preſident of Magdalen college, Oxford. Here he formed a church upon the independent plan, and was exceedingly diligent in promoting the intereſts of learning and piety. His public duties as a preacher did not prevent him from thoſe ſtudies which enabled him to become diſtinguiſhed as a writer. He attended Cromwell upon his death-bed, and was overheard to expreſs himſelf boldly and enthuſiaſtically confident of the protector's recovery; and it is affirmed that when the event proved him miſtaken, he exclaimed in a ſubſequent addreſs to God "thou haſt deceived us, and we are deceived." After the reſtoration he was diſmiſſed from his preſidentſhip, when he retired to London, where, however, he was permitted to continue in the exerciſe of the miniſtry till his death in 1679, when he had attained to his eightieth year. He was a conſiderable ſcholar, and a learned and eminent divine. In the common regiſter at Oxford he is deſcribed "in ſcriptis in re theologica quam plurimis Orbi notus." He was a high Calviniſt, but while he zealouſly enforced what he conceived to be the doctrines of Chriſtianity, he did not forget to enforce by every incitement in his power the neceſſity of pure moral conduct. He was author of numerous pious and controverſial pieces, ſermons, expoſitions, &c. ſome of which were printed during his life time, and inſerted, after his death, in a collection of his works publiſhed in five volumes folio, which continue to be read and quoted by Calviniſts of the preſent day. Neal's Hiſt of Puritans, by Toulmin.

Goodwin *Sands*, in *Geography*. See Godwin *Sands*.

GOOGINGS, in *Sea Language*, are clamps of iron bolted on the ſtern-poſt of a ſhip, whereon to hang the rudder and keep it ſteady; for which purpoſe there is a hole in each of them, to receive a correſpondent ſpindle bolted on the back of the rudder, which turns thereby as upon hinges.

GOOGOOS, in *Geography*, inhabitants of the inland territory of the iſland of Sumatra, covered with long hair, and little ſuperior to the ourang outangs of Borneo. See Sumatra.

GOOJINDERGUR, a town of Hindooſtan, in Sanore; 25 miles N.N.W. of Sanore.

GOOL, a river of Hindooſtan, which riſes near Burrawny, and runs into the Tapty, 8 miles S. of Chuprah.

Gool, ſignifies a ditch or trench for water; called alſo a goit, gurt, leat, &c.

GOOLE, a breach in a ſea-bank or wall; or a paſſage worn by the flux and reflux of the ſea. Vide 16 and 17 Car. II. cap. 11.

The word comes from the French, *goulet*, the gullet or neck.

GOOLGUNGE, in *Geography*, a town of Hindooſtan, in the circar of Chanderee; 25 miles E. of Chanderee.

GOOLLAH, a ſmall circar or province of Bengal, ſituated E. of Coos-Beyhar.

GOOMAH, a town of Bengal, 45 miles N. of Ramgur. N. lat. 24° 23'. E. long. 85° 54'.—Alſo, a town of Hindooſtan, in Bahar; 40 miles N.E. of Chittra.

GOOMBO, a town of Africa, in Bambarra. N. lat. 15° 3'. W. long. 5° 10'.

GOOMBOGANO, a town of Africa, in Kaſſan. N. lat. 14° 20'. W. long. 8° 50'.

GOOMGONG, a town of Hindooſtan, in Berar; 12 miles S of Nagpour.

GOOMERPUN, a town of Hindooſtan, in Oude; 16 miles S.W. of Azimgur.

GOOMPINA, a town of Hindooſtan, in Golconda; 20 miles N.E. of Culloor.

GOOMREPOUR, a town of Hindooſtan, in Allahabad; 20 miles E.N.E. of Jionpour.

GOOMTY, a river of Aſia, which riſes in the mountains of Kemaoon, and croſſing the country of Oude, joins the Ganges, about 15 miles N. of Benares.

GOONANGAPY, a ſmall iſland in the Eaſt Indian ſea, near the N. E. coaſt of Cumbava. S. lat. 8° 10′. E. long. 119° 24′.

GOONDWANAH, the ancient name of the province of *Nagpour*, which ſee.—Alſo, mountains of Hindooſtan, called "Konduannah," ſituated in the S. E. part of the country of Malwa, extending from Huſſingabad to Mundellah, about 170 miles long. N. lat. 22° 40′, to 23°. E. long. 78° to 81°.

GOOPAMOW, a town of Hindooſtan, in Oude; 20 miles W. of Kairabad.

GOOPIGUNGE, a town of Hindooſtan; 32 miles W. of Benares.—Alſo, a town of Hindooſtan, in the ſoubah of Agra. N. lat. 26° 24′. E. long. 79° 18′.

GOORACKPOUR, a province of Oude, bounded on the N. by Thibet, on the E. by Bettiah and Sarun, on the S. by Gazypour, and on the W. by Oude proper and Bahraitch, about 60 miles long and 50 broad. The capital of the ſame name is ſituated 65 miles E. of Fyzabad. N. lat. 26° 44′. E. long. 83° 30′.

GOORAH, the name of two towns of Hindooſtan; one in Oude and another in Allahabad.

GOORUNTY, a town of Hindooſtan, in the circar of Cicacole; 17 miles S. W. of Ganjam.

GOOS, a town of Nubia. N. lat 18°. E. long. 34° 18′.

GOOSANDER, in *Ornithology*. See Mergus *Merganſer*.

GOOSE, Anser, forms an order of birds in the Linnæan ſyſtem. (See Anseres.) The ſeveral ſpecies of geeſe belong to the genus of anas or duck under this order. See Duck.

Goose, a well-known bird, which, in many ſituations, may be highly beneficial to the farmer, as, where there are large waters and commons, and where the ſtubbles are abundant. It is valuable both for its fleſh, fat, and feathers.

The varieties of geeſe are numerous, but the large common kinds are probably the beſt for the uſes of the farmer.

Goose, *Ember*. See Colymbus *Immer*.

Goose, *Soland* or *Solan*, ſometimes called *gannet*, the Engliſh name of a large water-fowl, called by authors *Anſer Baſſanus*, and by Linnæus Pelecanus *Baſſanus*, which ſee.

Goose *Creek*, in *Geography*, a river of New Jerſey, which runs into the Atlantic, N. lat. 39° 53′. W. long. 74° 16′.—Alſo, a river of Kentucky, which runs into the Ohio, N. lat. 38° 10′. W. long. 86° 3′.—Alſo, a river of North Carolina, which runs into the Atlantic, N. lat. 34° 40′. W. long. 77° 21′.—Alſo, a river which falls into the Potowmac, about a mile S. E. of Thorpe, in Fairfax county, Virginia.

Goose-*dung*, in *Agriculture* and *Medicine*. See Dung and Chenocoprus.

Goose-*foot*, or *Wild Orach*, or *Good Henry*, in *Botany*. See Chenopodium.

Goose-*graſs*, the common name of a troubleſome weed that is frequently met with on clayey ſoils. It is beſt deſtroyed by cutting it in the ſummer, and keeping the land under the plough in good condition. See Galium *Aparine*.

Goose-*graſs*, *Great*. See Asperugo.

Goose *Iſland*, in *Geography*, a ſmall iſland in the gulf of St. Lawrence, near the coaſt of Labrador. N. lat. 50° 52′. W. long. 59° 10′.—Alſo, a ſmall iſland in Chriſtmas Sound, on the coaſt of Terra del Fuego.

Goose *Lake*, a lake of North America. N. lat. 52° 55′. W. long. 94° 45′.—Alſo, a lake of North America. N. lat. 54° 30′. W. long. 101° 21′.

Goose-*neck*, in *Sea Language*, is a ſort of iron hook fitted on the inner end of a boom, and introduced into a clamp of iron or eye-bolt, which encircles the maſt, or is fitted to ſome other place in the ſhip, ſo that it may be unhooked at pleaſure.

Goose *River*, in *Geography*, a river of America, which runs into the Miſſiſippi. N. lat. 43° 14′. W. long. 93° 56′.—Alſo, a river of South Carolina, which runs into Cooper's river. N. lat. 33° 2′. W. long. 79° 57′.

Goose-*wings of a ſail*, in *Sea Language*, denote the clues or lower corners of a ſhip's main-ſail, or fore-ſail, when the middle part is furled or tied up to the yard.

Goose-*wing*, at *Sea*, a certain manner of fitting a ſail, which is thus performed: when a ſhip ſails before a wind, or with a quarter-wind, and in a freſh gale, the ſeamen ſometimes, to make the more haſte, unparal the mizen-yard, and then they launch out both ſail and yard over the quarter on the lee-ſide, fitting guyes at the farther end, to keep the yard ſteady with the boom, and this booms out the mizen-ſheet. This they do to give the ſhip the more way, which otherwiſe, with theſe winds, the mizen-ſail could not do; and this ſail, ſo fitted, is called a *gooſe-wing*, and ſometimes a *ſtudding-ſail*.

GOOSEBERRY Bush, *Groſſularia*, in *Botany*, is a ſpecies of the *ribes* in the Linnæan ſyſtem. See Ribes.

The gooſeberry-buſh is propagated either by ſuckers or cuttings, but the latter way is preferable, as the roots are leſs ſubject to ſhoot out ſuckers afterwards.

The beſt ſeaſon for planting the cuttings is in autumn, juſt before the leaves begin to fall; obſerving always to take the handſomeſt ſhoots, and to pick them from ſuch branches as produce the greateſt quantity of fruit. The cuttings ſhould be about ſix or eight inches long, and ſhould be planted in a bed of light earth expoſed to the morning ſun; they muſt be planted about three inches deep, and watered to help their taking root. The ſhoots ſhould be rubbed off from theſe plants as they put out, except thoſe at the top, that there may be a regular ſtem. In the October following, they ſhould be removed to a bed of fine light earth, and planted in rows at three feet diſtance, and one foot aſunder in the rows. They ſhould remain here one year, and the croſs branches at times be cut off, as alſo the lower ones, ſo as to keep a clean ſtem about a foot above the ground. They will be then fit to plant out where they are to ſtand, which ſhould be in a light ſandy loam. They ſhould be kept from the ſhade of other trees; and to have the fruit in its utmoſt perfection, ſhould be ſet in an expoſed place in rows of eight feet aſunder, and each of the ſhrubs ſix feet from the others in the rows. The beſt time for tranſplanting them is in October, when the leaves begin to decay. Miller.

Gooseberry, in *Agriculture*, is a plant that may ſometimes be employed in the forming of hedge-fences, eſpecially that ſort known in the North by the title of Ironmonger.

Gooseberry *Caterpillar*, in *Gardening*, the common name of a very deſtructive inſect to the gooſeberry and ſome other plants. Many different methods of deſtroying it have been propoſed, but with little ſucceſs.

Gooseberry *of Barbadoes*. See Cactus.

Gooseberry *Tree*. See Melastoma.

Gooseberry-*galls*, in *Natural Hiſtory*, the name given by authors to a ſpecies of protuberances of the gall kind, found very frequently on the oak. They are of a roundiſh figure, and ſometimes adhere to the tree by a ſhort pedicle, but more frequently by a part of their ſpheric ſurface. They are uſually found on the under ſide of the leaves of the oak, but ſometimes on the young ſhoots, and ſometimes on the pedicles of the leaves.

They are moſt frequent in ſpring, but they are found at all times when the leaves are upon the trees. Theſe galls are greeniſh at firſt, and afterwards become yellowiſh, and finally red; in which laſt ſtate they very much reſemble the ſmall red gooſeberry. They are very ſoft to the touch, and when opened are found to contain a juicy ſubſtance, with a cavity in the midſt, in which there is lodged a ſingle inſect. This, according to the time in which the gall is opened, is found in the form of a white worm, or elſe of a white chryſalis, or finally of a ſmall ſhort-bodied four-winged fly of a black colour; for the creature does not leave the gall to go through any of its changes, but paſſes all its ſtates in it. The gall, in all theſe caſes, is found whole and unhurt; but if one is opened in which there is a hole pierced, this is ſure to be found empty, that being the paſſage by which the fly has made its way out. Reaum. Hiſt. Inſ. vol. vi. p. 214.

Gooseberry *Iſlands*, in *Geography*, ſmall iſlands near the E. coaſt of Newfoundland; 24 miles N.W. of Cape Bonaviſta.

Gooseberry *Rocks*, dangerous rocks lying on the coaſt of Eſſex county, in the ſtate of Maſſachuſetts.

GOOTA, a town of Hindooſtan, in Goondwanah; 10 miles S. of Nagpour.

GOOTOKA, a town of Hindooſtan, in the circar of Ruttunpour; 5 miles S. of Ruttunpour.

GOOTY, or Gutti, a town and fortreſs of Hindooſtan, the capital of a diſtrict in Myſore; 170 miles N. of Seringapatam. It is ſituated on a hill beyond the river Pennar, or Pen-aur, and towards Adoni; and was formerly the ſeat of government of a Mahratta prince; but at the death of Tippoo, the town and diſtrict were aſſigned to the Nizam. N. lat. 15° 15'. E. long. 77° 48'.

GO-OUT, in *Mining*, is ſometimes uſed to expreſs the appearance of the edge of a ſtratum at the ſurface; otherwiſe called the baſſet, crop, out-going, or out-burſt of that ſtratum; and ſuch ſtrata are ſaid to go-out, burſt-out, run-out, head-out, want-cover, &c.

When the ore in a vein ſuddenly ends in the deads or gangue, it is ſaid to go-out; alſo, when a ſtratum of coals ends abruptly againſt a fault, or wall of gravel filling a fault, or baſſet under a heap of gravel, as is not uncommon in the ſouth of Derbyſhire, it is ſaid to go-out, and ſo of the irregular or feather-edge maſſes which are ſometimes met with in the ſtrata accidentally, or without being continuous like all the regular ſtrata, however thin.

GOPALCHITTY, in *Geography*, a town of Hindooſtan, in Coimbétore; 18 miles N.W. of Erroad.

GOPALGUNGE, a town of Bootan; 58 miles N. of Dinagepour.

GOPALNAGUR, the name of two towns in Bengal; one 25 miles S.S.E. of Kiſhenagur, and another 30 miles E.S.E. of Dacca.

GOPALPOUR, the name of ſeveral towns in Hindooſtan, one 8 miles N. of Hurdah, a ſecond, 12 miles N. of Goragot, a third, 15 miles N. of Gurrah, a fourth, 23 miles S. of Bahar, a fifth, 20 miles N.W. of Narva, a ſixth, 20 miles S. of Goorackpour, a ſeventh, 38 miles S. of Fyzabad, an eighth, 25 miles N. of Amedabad

GOPALDROOG, a fortreſs of Myſore; 36 miles E. of Seringapatam.

GOPAULGUNGE, a town of Bengal. N. lat. 23° 2'. E. long. 89° 56'.

GOPAULNAGUR, a town of Bengal, 42 miles S. of Burdwan. N. lat. 22° 31'. E. long. 88 .

GOPEER, a town of Bengal; 15 miles E.N.E. of Ramgur.

GOPERAPILLY, a town of Golconda; 20 miles E.S.E. of Hydrabad.

GOPHNA, Gophnith, or *Gaphna*, in *Ancient Geography*, a town of Paleſtine, and chief place of one of the ten toparchies of Judah. Euſebius places it fifteen miles from Jeruſalem, towards Sichem.

GOPLO, in *Geography*, a lake of Poland, in the palatinate of Brzeſc, 16 miles long, and four wide.

GOPPINGEN, a town of the kingdom of Wurtemberg, ſituated on the Vils, in a fertile country, having conſiderable woollen manufactures, and near it a medicinal ſpring; 20 miles N.N.W. of Ulm. N. lat. 48° 47'. E. long. 9° 41'.

GOR, a town of Perſia, in the province of Farſiſtan; 57 miles N.W. of Schiras.—Alſo, a town of Italy, in the department of the Mela; 8 miles S. of Breſcia.

Gor, a name given by ſome writers to a very lofty tree, which bears a fruit like the cheſnut; it grows principally on the banks of the river Niger, and that not near the ſea, but far up the country.

Gor-*cock*, in *Ornithology*, the name of a bird of the gallinaceous kind, called by authors the lagopus altera, and by many the moor-cock, or red game; it is of the ſhape of the partridge, but is half as large again. See Grouse and Tetrao *Lagopus*.

GORA, in *Geography*, a town of Hindooſtan, in the circar of Chandail; 20 miles W. of Saipour.

GORACALLY, a town of Bengal; 12 miles S.S.W. of Mahmudpour.

GORAGOT, a province of Bengal, bounded on the N. by Rungpour, on the E. by Radjoohow, Patladah, and Iſlamabad, on the S. by Bettoriah and Pargunnah, and on the W. by Dinagepour; about 55 miles long, and from 12 to 30 broad. Its capital, Goragot, is diſtant 80 miles N.N.E. from Moorſhedabad. N. lat. 25° 14'. E. long. 89° 22'.

GORAI, a town of Poland, in Galicia.

GORAM, a ſmall iſland, being one of the Moluccas, in the Eaſt Indian ſea, S.E. of Ceram; reputed the moſt eaſtern boundary of Mahometaniſm. It has thirteen moſks. S. lat. 3° 42'. E. long. 121° 36'.

GORANTO, a town of Aſiatic Turkey, in Caramania; 80 miles S.W. of Satalia.

GORAPARI, a town of Brazil, at the mouth of a river of the ſame name, which runs into the Atlantic. S. lat. 20° 40'.

GORBARA, a town of Corſica; 8 miles N.E. of Calvi.

GORBATA, a town of Africa, in Biledulgerid, anciently "Orbita;" 12 miles S.W. of Gafſa.

GORBATOV, a town of Ruſſia, in the government of Niznei Novogorod. N. lat. 56 5'. E. long. 43° 14'.

GORCA. See Gorkah.

GORCE, or Gourt, denotes a weir. By ſtat. 25 Edw. III. cap. 4. it is ordained, that all gorces, mills, weirs, &c. levied or ſet up, whereby the king's ſhips and boats are diſturbed, and cannot paſs in any river, ſhall be utterly pulled down, without being renewed. Sir Edward Coke derives this word from *gurges*, *a deep pit of water*, and calls iſ a *gors*, or *gulf*; but this ſeems to be a miſtake, for in Doomſday it is called *gourt* and *gort*, the old French word for a *weir*.

GORCHWICH, in *Geography*, a town of Saxony, in the Vogtland, 18 miles S.S.W. of Gera. N. lat. 50° 22′. E. long. 11° 53′.

GORCUM, probably a corruption of *Gorichem*, a town of Holland, ſituated on the river Linge, at its union with the Wahal. From the ſteeple of the principal church may be ſeen 22 walled cities, beſides a great number of towns and villages; before the revolution it had one pariſh-church, and three religious houſes; 12 miles E. of Dort. N. lat. 51° 52′. E. long. 4° 50′.

GORDENE′, in *Ancient Geography*, a country of the Greater Armenia, according to Ptolemy; which country is called "Gordyené" by Strabo and by Plutarch in his life of Lucullus.

GORDES, in *Geography*, a town of France, in the department of Vaucluſe, and chief place of a canton in the diſtrict of Apt; 9 miles W. of Apt. The place contains 2812, and the canton 6430 inhabitants, on a territory of 167½ kiliometres, in 8 communes.

GORDEWARE Point, a cape of Hindooſtan, on the coaſt of Rajamundry, at the mouth of the Godavery. N. lat. 16° 42′. E. long. 82° 28′.

GORDIÆUS Mons, in *Ancient Geography*, a mountain of the Greater Armenia. Ptol.

GORDIANI, M. Antonius Gordianus, in *Biography*, Roman emperor, born A.D. 157, was ſon of Metius Marullus, a ſenator deſcended from the Gracchi, by Ulpia Gordiana, of the family of the emperor Trajan. He became poſſeſſed of a great eſtate, with which he lived in a ſtyle of magnificence, but without paſſing the bounds of moderation. He was a patron of literature and literary men, and a proficient in eloquence and poetry. He wrote a poem in thirty books, to celebrate the reigns of Titus and M. Aurelius Antoninus. When he ſerved the office of edile, he entertained the people with a ſplendour which no private perſon had for a long time exhibited, and his ſhows were exhibited every month in the year while he was in office. There is, however, no reaſon for ſuppoſing that he was over ambitious of coming forwards into public life, for it was not till his fifty-fifth year that he was elected conſul in conjunction with the emperor Caracalla. He might, perhaps, be unwilling to riſque the ſafety of his perſon in thoſe turbulent times; and it has been thought extraordinary that under ſo jealous a tyrant he ſhould venture upon the profuſe expences which diſtinguiſhed his conſulſhip not only in the imperial city, but in various parts of Italy alſo. He enjoyed the ſame honour a ſecond time in the reign of Alexander Severus, who expreſſed his high eſteem for him by confirming his nomination to the government of Africa as proconſul. In this important poſt he diſplayed ſo much equity and beneficence, that he was more beloved in the province than any of his predeceſſors. Under the emperor Maximin, in the year 237, a ſedition was excited againſt the rapacity of an officer in the government of Africa, and the perpetrators, to avoid the vengeance of a cruel and incenſed ſovereign, appeared in open rebellion and inſiſted upon Gordian's aſſuming the purple. He remonſtrated with the conſpirators, but their reſolution was formed, and at the age of fourſcore he was forced to appear in a character, after which he had never aſpired. They aſſociated with him, to alleviate his cares, the younger Gordian, a man of voluptuous habits, but who was of a mild diſpoſition, and attached to letters. A library of ſixty-thouſand volumes, bequeathed him by his tutor Serenus Sammonicus, gave him reputation in the literary world, which he maintained by writing both in proſe and verſe. This young man had been elevated to the office of queſtor by the deſpicable Heliogabalus; nevertheleſs, the confidence placed in his integrity, and knowledge of the laws, by Alexander, who created him prefect of Rome, and who always paid great deference to his advice, was much in his praiſe. He ſhared in the elevation of his father, and they were declared joint emperors. The Gordians removed to Carthage, whence they ſent letters to Rome, announcing their election. Maximin was at that time abſent, and the ſenate willingly ſanctioned the choice of the Africans, and declared Maximin a public enemy. In the mean time, a change took place in Africa, which annulled all their projects. Capelianus, governor of Mauritania, who had been always upon ill terms with Gordian, aſſembled a body of veterans, declared for the reigning emperor, and marched to Carthage. The younger Gordian ſallied out to oppoſe him with his guards, but he was ſoon defeated and ſlain. Capelianus entered the city, which ſo much alarmed the elder Gordian, that to prevent his falling into the hands of his enemy, he ſtrangled himſelf in his apartment with his girdle. This event happened in June 237, and within a few weeks of his aſſuming the office of emperor. Gibbon.

Gordian III., Roman emperor, grandſon of the elder Gordian, was but thirteen years old when he was choſen emperor, in connection with Maximus and Balbinus. He was created Cæſar, and aſſumed the family name. His two colleagues were in a few months murdered by the Pretorian bands, and the youthful Gordian remained ſole emperor. His perſon and manners excited univerſal favour, and the ſenate, people, and army united in giving him the endearing appellation of their ſon. In the commencement of his reign he was governed by his mother's eunuchs, who abuſed his authority, and ſet the honours and offices of the empire up to ſale. He was, however, happily reſcued from this diſgraceful condition by Miſitheus, a man of learning, to whom he was alſo indebted for literary inſtruction and advice. In the year 241 he married the daughter of Miſitheus; and raiſing his father-in-law to the poſt of præfect-prætorio, committed to him the principal direction of public affairs. He proved himſelf worthy of the important truſt confided in him, and diſcharged the duties of a ſtateſman and general, as well as he had maintained thoſe of a more private ſtation. By his perſuaſion, the young emperor accompanied him in 242, in an expedition to the Eaſt, for the purpoſe of repelling an invaſion from Sapor king of Perſia. Under his guidance, Gordian relieved Antioch, croſſed the Euphrates, defeated Sapor, and recovered the whole of Meſopotamia. The young emperor did not aſſume the glory of the deeds, but, in a letter to the ſenate, announcing the ſucceſſes, he modeſtly aſcribes them to the conduct, the experience, and wiſdom of Miſitheus, who ſhortly after died. During the whole expedition Miſitheus had watched over the ſafety and diſcipline of the army, while he prevented their murmurs by maintaining a regular plenty in the camp, and by eſtabliſhing ample magazines of vinegar, bacon, ſtraw, barley and wheat, in all the cities of the frontiers. The proſperity of the emperor expired with Miſitheus; he was ſucceeded in the office of præfect by Philip, an Arab by birth, and conſequently, ſays Gibbon, in the earlier part of his life, a robber by profeſſion. He was a man of conſiderable military talents, but ambitious, and deſtitute of true moral principle. His energy and boldneſs prompted him to aſpire to the throne, and his abilities were employed to ſupplant, not to ſerve his indulgent maſter. By his arts diſcontents were fomented among the troops, which induced them to demand that his miniſter Philip ſhould be aſſociated with Gordian as partner in the empire. This was not ſufficient to ſatisfy his ambitious views; the young emperor was ſacrificed at his inſtigation; he was put to death near the banks of the Euphrates, in March 244, after a reign of five years and eight months. A ſepulchral monument was erected to his memory on the ſpot where he was killed. Gibbon.

Gordian, a term in *Hiſtory*. Gordian knot was a knot made in the leathers or harneſs of the chariot of Gordius, king of Phrygia, and father of Midas; ſo very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he ſhould be maſter of Aſia who could untie this knot. Alexander having undertakan it, and fearing that, if he ſhould not be able to effect it, it would be deemed an ill augury, and prove a check in the way of his conqueſts, cut it aſunder with his ſword; and thus, ſay Quintus Curtius, either accompliſhed the oracle, or eluded it. But Ariſtobulus gives a different account of this matter. See Arrian, lib. iii. cap. 20. and Plut. in Vit. Alex.

Some will have the phraſe derived from Gordius who tied the fatal knot; others from Gordium, a city in Phrygia, where the knot was made.

GORDIUM, in *Geography*, a town of Aſia, in Phrygia, ſituated on the river Sangar; afterwards called Juliopolis.

GORDIUS, in *Zoology*, a genus of Vermes, the eſſential character of which conſiſts in the body being round, filiform, naked or ſmooth, and of equal thickneſs throughout.

Linnæus, and after his example the French naturaliſt Bruguière, has placed the animals of this genus among the inteſtinal vermes, an order of beings to which, from their general ſtructure, they ſeem to bear no very remote alliance: and this ſimilarity is ſtill more ſtrongly evinced in the habits of thoſe ſpecies which occaſionally penetrate into the fleſh of men and animals, and therein for a while derive their ſuſtenance from the blood and other fluids. Notwithſtanding this analogy, under ſuch circumſtances we cannot but agree with Lamarck that it is impoſſible to conſider them as internal vermes with propriety, ſince they only occaſionally reſide in the bodies of animals as before mentioned, and in their habits and manners of life at other periods differ moſt eſſentially: they are literally aquatic animals, with carnivorous appetites; though for a certain length of time they can ſubſiſt like the true inteſtinal vermes, when by any accidental circumſtance they happen to inſinuate themſelves into the fleſh of a living animal.

At the head of this tribe we may juſtly place the ſpecies *medinenſis*, or hair worm of the Indies, a pernicious creature, referred to the genus Gordius by Linnæus in the lateſt edition of his Syſt. Nat., but from which it was afterwards removed by his editor Gmelin to that of Filaria. This removal we deem unneceſſary, and under this perſuaſion wiſh to reſtore the ſpecies to its former ſituation in the genus Gordius.

Species.

Medinensis. Body entirely pale. Linn. Sloane Jam. &c.

This very remarkable creature is often from ten to twelve or even fifteen feet in length, and in thickneſs not exceeding a horſe-hair. It is well known by its diſaſtrous effects as an inhabitant of both the Indies, where it lives in marſhy places, and is frequently obſerved on the ground in the morning dew. In this ſituation it eaſily creeps up, and entwines itſelf round the naked legs of the negro ſlaves, or animals, and penetrating the ſkin, buries itſelf ſpeedily in the fleſh, where it cauſes the moſt violent pains, accompanied with troubleſome itchings, and oftentimes inflammation and fever. The moſt certain means of extricating the worm is to make an inciſion in the part of the fleſh at which its entrance was effected, ſo as to obtain ſecure hold of either of the extremities, or the head if poſſible, and this being made faſt to a ſmall ſtick by means of a piece of ſilk, the animal may be gradually drawn out of the wound by turning the ſtick round a little each day. The utmoſt circumſpection is requiſite in performing this operation, for if by being too much ſtrained the worm ſhould break, the part remaining within the fleſh grows with increaſed vigour, gangrene appears almoſt immediately, and death itſelf enſues very ſhortly.

Aquaticus. Pale brown, with blackiſh extremities. Linn. *Gordius ſeta*, Müll. *Vitulus aquaticus*, Geſn. *Meerwijn*, Jonſt. *Chætia*, Hill. &c.

This ſo entirely reſembles a hair of from four to ſix inches in length, that except by its motions it could be in no manner diſtinguiſhed from a ſubſtance of that kind by the caſual obſerver; its internal ſtructure is equally remarkable alſo for its ſimplicity, conſiſting merely, as it appears, of a canal extending from one end to the other, and both the mouth and vent are the moſt ſimple poſſible, ſince a ſmall vent conſtitutes the firſt, and a groove or hollow the latter. Its ordinary places of reſidence are ſtagnant waters; in pools and ditches, or in very tranquil rivers, as the agitation of turbulent waters would deſtroy its tender frame. During winter it remains buried deep in the clay, from whence it emerges in ſpring, and is found in the water during the ſummer months, where it is frequently obſerved, and from its appearance is vulgarly imagined to be the offspring of *horſe hair* dropped by accident into the water. It twiſts itſelf into various contortions; and it is affirmed that its bite will occaſion the complaint called a whitlow. A fact ſtill more extraordinary, and which appears in ſome meaſure to be authenticated with tolerable accuracy, is the retentive power of animation, which this creature poſſeſſes in a very ſuperior degree, though not by any means to the extent that certain naturaliſts conceive. Some writers affirm, indeed, that it has been known to recover the free exerciſe of its vital functions upon being ſteeped for a ſhort ſpace of time in water, after having remained in a dried ſtate for weeks, months, and even years, and when of courſe it might be naturally conceived the moſt latent ſpark of life muſt be extinct. If theſe latter aſſurances have not ariſen from the reſult of ſome very ſuperficial experiments, they are at leaſt to be received with caution, ſince their obſervers ſeem to believe that theſe animals partook alſo in ſome meaſure of the reproductive properties of the polype, and which more recent obſervations prove to be erroneous; we cannot, therefore, upon the whole, avoid concluding that although the animals of this kind are extremely tenacious of life, there is no foundation in truth for the very extraordinary aſſertions above related.

Argillaceus. Body uniformly yellowiſh. Linn.

Very much reſembles the laſt, and like that ſpecies is found in the clay at the bottom of ſtagnant waters.

Filum. Body filiform and whitiſh, Müll.

Extremely ſlender, tapering at one end, and hyaline. Found in the bark of old wooden pipes which had been placed in the ground for the conveyance of water.

Lacteus. Body uniformly white and opaque. Müll.

Occurs in myriads in ſtagnant water from the month of July till September. When touched, this ſpecies contracts itſelf in a moment, and then again expands immediately.

Arenarius. Fulvous and obtuſe. Müll.

Inhabits the bottom of Chriſtians bay, in Norway.

GORDON, Bernard, in *Biography*, a French phyſician of the thirteenth century, is ſaid to have conferred honour on the medical faculty of Montpellier, where he began to teach in the year 1285. As was the cuſtom of the time, he took his ſurname from the place of his birth, (Gordon in Rouvergne,) and called himſelf Bernardus de Gordonio, and not Gordonus, as it is commonly written. According to the accounts of ſome writers, who place the death of this phyſician in 1305, he taught at Montpellier only twenty years; but Renchin affirms, that he was living in 1318. He left a conſiderable number of treatiſes, which were publiſhed together at Ferrara in 1487, at Venice in 1494, at Paris in 1542, and at Lyons in 1550. Eloy. Dict. Hiſt.

Gordon, Mr., in the year 1744 played the firſt violin in Drury-lane play-houſe. He was a young man, born in Norfolk, who had travelled to Italy for improvement. He was very near-ſighted, and always played in ſpectacles. He ſucceeded Charke, had a ſtrong hand, good tone, and was well fitted to his ſtation. He generally played a concerto in the ſecond muſic, as was then the practice, which was very attractive. He was brother to the ſubject of the following article.

Gordon, ———, an eminent performer on the violoncello, the ſon of a clergyman in Norfolk, and many years the firſt violoncello at the opera. He was remarkable for the fulneſs of his tone, and perfect execution of whatever he undertook, though far ſurpaſſed by ſubſequent players in the uſe of the bow, and knowledge of the finger-board. He lived reputably, had many powerful friends, and realiſed a competence by his profeſſion.

In 1765, Meſſrs. Gordon, Vincent, and Crawford, undertook the opera regency in the Haymarket. The two firſt were experienced profeſſors, and the third had been many years treaſurer under different managers. Gordon, an excellent performer on the violoncello; and Vincent, a ſcholar of the celebrated Martini, long a favourite on the hautbois. His father was a baſſoon player in the Guards, and his brother, James Vincent, who died young, was joint organiſt of the Temple with Stanley, and a brilliant performer. Mr. T. Vincent, the impreſario, had been in great favour with the late prince of Wales, father to his preſent majeſty; had acquired a conſiderable ſum of money in his profeſſion, which he augmented by marriage. However, the ambition of command, though of ſo froward a family as an opera, vocal, and inſtrumental band, turned his head and his purſe inſide out; in ſhort, he ſoon became a bankrupt, ſculked in indigence during the reſt of his life; and his colleagues, though they eſcaped utter ruin, were not enriched by the connection.

Gordon, Alexander, a learned writer of the eighteenth century, was a native of Scotland. He was well acquainted with the Greek and Latin languages, and being a good draughtſman, he was enabled to derive peculiar advantages from a long reſidence in Italy, and from his travels in other parts of Europe. He was engaged as ſecretary to the ſociety for the encouragement of learning; and to the Egyptian club, and to the Antiquarian ſociety. He afterwards accompanied governor Glen to Carolina, where he occupied various poſts in the province, and received a handſome grant of land. Here he died, leaving a good eſtate to his family. He was author of “Itinerarium Septentrionale,” or a journey through moſt parts of Scotland, illuſtrated with copper plates. This was publiſhed in 1726, and in 1732 he gave additions and corrections to it, containing an account of Roman antiquities in Scotland, and ancient monuments in the north of England. He wrote likewiſe “The Lives of Pope Alexander VI., and his Son Cæſar Borgia.” “A complete Hiſtory of ancient Amphitheatres, tranſlated from the Italian.” “An Eſſay towards explaining the hieroglyphical Figures on the Coffin of a Mummy.” “Twenty-five Plates of all the Egyptian Mummies in England, and other Egyptian Antiquities.” Gen. Biog.

Gordon, Andrew, was born in 1712 near Aberdeen. He was ſent to Ratiſbon, where he applied himſelf to polite literature. In 1731 he made a tour through Auſtria, Italy, and France, and on his return in the following year entered into the order of the Benedictines in the Scots monaſtery, where he applied to philoſophy, and was ordained prieſt. In 1735, he went to Salzburg to ſtudy the law, and he attended the theological lectures till he was invited, in 1737, to be profeſſor of philoſophy at Erfurt. His diſcoveries in electricity made his name known to the philoſophers in Holland, France, Italy, and England, and he is mentioned by Dr. Prieſtley as the firſt perſon who uſed a cylinder inſtead of a globe in electric experiments. His firſt work on this ſubject was entitled “Phenomena Electricitatis Expoſita,” 1744; and in the following year he publiſhed in 3 vols. 8vo. “Philoſophia utilis et jucunda.” He was author of an “Impartial Account of the Origin of the preſent War in Great Britain,” and of “Phyſicæ Experimentalis Elementa.” Gen. Biog.

Gordon, James, a Scotch Jeſuit, was born in the year 1543. He left his native country, and went to Rome, where he entered the ſociety of Jeſus, in 1563. He became diſtinguiſhed for deep and extenſive learning, and was ſent on religious miſſions into Germany, Denmark, and the Britiſh iſles, where he is ſaid to have ſuffered much on account of his attachment to the Catholic faith. He died at Paris in 1620, leaving behind him a work in two volumes 8vo. entitled “Controverſiarum Chriſtianæ Fidei Epitome.”

There was another Scotch Jeſuit of the ſame name, and contemporary with the above, who wrote a commentary on the whole bible, which he publiſhed at Paris, in three volumes folio, under the title of “Biblia ſacra, cum Commentariis ad ſenſum Literæ, et explicatione Temporum, Locorum, Rerumque omnium quæ in ſacris Codicibus habent obſcuritatem: una cum Textu Biblico.” This work is well ſpoken of by Dupin. He was author likewiſe of a work on Chronology: and of “A Syſtem of moral Theology,” &c. Moreri.

Gordon, Thomas, a native of Kirkcudbright, in Scotland, after having received an academical education in his own country, came to London, and maintained himſelf by teaching the learned languages. His talents were made known to people of conſequence, and he was employed by the earl of Oxford in queen Anne's reign as a political writer. He wrote in defence of biſhop Hoadley in the Bangorian controverſy, and became the aſſiſtant and partner of Mr. Trenchard, in his literary undertakings. They publiſhed, in conjunction, a ſeries of papers, entitled “Cato's Letters;” and the “Independent Whig,” which Mr. Gordon continued alone after the death of Trenchard. When this event took place, ſir Robert Walpole engaged Gordon as one of the writers in defence of his meaſures, and procured him a place, which he held as long as he lived. Mr. Gordon made himſelf known by tranſlations of Tacitus and Salluſt, as well as by his political pieces. To theſe tranſlations he prefixed diſcourſes relative to ſubjects of each original author. He died in 1750, at the age of ſixty-ſix. Some of his poſthumous tracts appeared in two works, entitled “A Cordial for Low Spirits;” and “The Pillars of Prieſtcraft and Orthodoxy ſhaken.” He was a diſtinguiſhed writer in favour of civil and religious liberty, and is highly eſteemed by the friends of freedom for the manly ſpirit with which he ſupported its cauſe againſt tyranny of every kind. Gen. Biog.

GORDONA, in *Geography*, a town of Naples, in the county of Moliſe; ſix miles S.W. of Moliſe.

GORDONIA, in *Botany*, named by Mr. Ellis, in the Philoſophical Tranſactions for 1770, in honour of Mr. James Gordon, an eminent nurſeryman at Mile-end, near London, who introduced many new plants to the knowledge of the curious, or rather cultivated with great ſkill and ſucceſs ſuch as were communicated to him, from various quarters, by the collectors and naturaliſts of that day, among whom were Bartram, Collinſon, Ellis, and many others. He was a frequent correſpondent of Linnæus, and ſent him ſeveral living plants, eſpecially of North American origin. Linn. Mant. 556. Syſt. Nat. ed. 14. 631. Schreb. 471. Willd. Sp. Pl. v. 3. 840. L'Herit. Stirp. Nov. 156. Cavan. Diſſ. faſc. 6. 307. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 231. Juſſ. 275, Lamarck. Illuſtr. t. 594. Dict. v. 2. 770. Claſs and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſimple, inferior, of five roundiſh, concave leaves. *Cor.* Petals five, large, obovate, or obcordate, concave, cohering at their baſe, ſomewhat unequal. *Stam.* Filaments very numerous, thread-ſhaped, united at their baſe into a thick cup-ſhaped body; anthers oval, erect. *Piſt.* Germen ſuperior, ovate or nearly globoſe; ſtyle ſhort, columnar, obſcurely five-ſided, ſometimes five-cleft; ſtigmas five, acute, horizontal. *Peric.* Capſule ovate or globular, of five cells and five valves, the partitions from the middle of the valves, which are deeply cloven at their baſe. *Seeds* in two rows in each cell, angular, winged, inſerted into a five-angled central column.

Eſſ. Ch. Calyx ſimple. Style columnar. Stigma five-cleft. Capſule of five cells. Seeds ſeveral, in two rows, winged.

1. G. *Laſianthus.* Linn. Mant. 570. Curt. Mag. t. 668. Cavan. Diſſ. t. 161. (Hypericum Laſianthus; Linn. Sp. Pl. 1101. Alcea floridana quinquecapſularis, &c.; Pluk. Amalth. t. 352. f. 3.) Loblolly Bay.—Flower-ſtalks elongated. Leaves coriaceous, ſmooth. Capſules ovate.—Native of ſwamps in South Carolina, where it forms a very handſome tree, but is with great difficulty cultivated in England. It blooms in Auguſt and September. We have ſeen this plant flowering in great perfection at Kew 25 years ago. The *leaves* are ſcattered, on ſhort ſtalks, elliptic-lanceolate, three to five inches long, bluntiſh, with numerous ſhallow ſerratures, veiny, ſmooth on both ſides, of a fine ſhining green, like thoſe of *Prunus Lauro-ceraſus* above, paler beneath. *Stipulas* none. *Flowers* ſolitary, on ſimple axillary ſtalks, thrice as long as the footſtalks, as large as a moderate roſe, white with yellow ſtamens, very handſome but inodorous. A pair of deciduous fringed bracteas, a little below the flower, are called by Cavanilles an outer calyx. Authors have differed about the claſs of this plant in the Linnæan ſyſtem, the filaments cohering imperfectly and irregularly together in parcels, beſides being connected by one common fleſhy baſe. If this baſe be called a nectary, for which there is no good reaſon, the flower is polyadelphous, but we think, with Dr. Sims, and moſt others, that it is monadelphous.

2. G. *Hæmatoxylon.* Swartz. Ind. Occ. 1199.—Blood-red Wood Tree.—Flower-ſtalks very ſhort. Leaves elliptic-lanceolate, pointed, ſerrated, ſmooth. Petals inverſely heart-ſhaped. Style deeply five-cleft.—Native of dry woody places on lofty mountains, in the weſt ſide of Jamaica; Dr. Swartz, from whom we have ſpecimens. A *tree*, whoſe ſtem is from twelve to ſixteen feet high, with a ſmooth greyiſh bark, and round ſlender ſtraight compound leafy branches, *Leaves* two or three inches long, ſcattered, on footſtalks. elliptic-lanceolate, tapering at both ends, with a bluntiſh recurved point, ſmooth on both ſides, leſs coriaceous than in the former, their margin ſomewhat revolute, with numerous ſhallow ſerratures. *Flowers* from the boſoms of the upper leaves, ſolitary, on very ſhort ſtalks, not ſo long as the footſtalks, bearing one or two unequal bracteas; their petals pale fleſh-coloured, unequal, deeply lobed, ſcarcely ſo large as thoſe of *G. Laſianthus*, but flatter and more ſpreading. *Germen* ſilky, furrowed. *Style*, according to Dr. Swartz, divided into five. *Capſule* oblong, rather pointed. *Seeds* two in each cell, with an abrupt wing.—This tree was omitted by Dr. Swartz in his Prodromus, and is little known to botaniſts, having never yet been brought to Europe. It flowers in February and March. The wood is hard and of a blood-red, valued in Jamaica for making ornamental furniture, but as yet not known, or not diſtinguiſhed, by European workmen. The peculiar ſtructure of the ſtyle does not conſtitute any generic diſtinction here, any more than in the neighbouring genus *Stuartia*. See Sm. Exot. Bot. v. 2. 101.

3. G. *pubeſcens.* L'Herit. Stirp. Nov. 156. Cavan. Diſſ. t. 162. Vent. Jard. de la Malmaiſon, t. 1.—Flowers nearly ſeſſile. Leaves downy beneath. Capſules globoſe.—Native of South Carolina, now not uncommon in green-houſes, flowering in autumn. A handſome *ſhrub*, whoſe branches, calyx, and the backs of its leaves, are clothed with fine white depreſſed down. The *flowers* moſt reſemble thoſe of the firſt ſpecies, but one petal is conſiderably more concave than the reſt, ſhorter, and downy, approaching to the nature of the calyx. The flower-ſtalks are extremely ſhort and thick. *Leaves* obovato-lanceolate, acute, with ſhallow ſerratures, ſmooth and of a fine green above. Ventenat's figure, drawn by Redouté, the firſt in the ſplendid Jardin de la Malmaiſon, is one of the fineſt repreſentations of a plant that can any where be ſeen, except that the French mode of printing in colours gives indiſcriminately an idea of a downy ſurface, ſo that in this caſe both ſides of the leaves look alike.

4. G. *Franklini.* L'Herit. Stirp. Nov. 156. (Franklinia Alatamaha; Marſhall. Arbuſt. 49.)—"Flowers ſeſſile. Leaves ſmooth. Capſules globoſe."—Native of South Carolina. *Flowers* ſeſſile, ſolitary, large, white, very much admired in their native country, but we have not heard of their being produced in Europe, nor have we ſeen even a dried ſpecimen. The *capſule*, according to L'Heritier, is "globoſe and umbilicated. *Seeds* numerous in each cell, imbricated in two rows, ſlightly angular, much like thoſe of the Cypreſs, the angles ſomewhat bordered. *Leaves* alternate, on ſhort foot-ſtalks, oblong, toothed, attenuated at the baſe, and ſmooth."—Marſhall and Bartram ſay the flowers ſmell like a china orange, and are often five inches in diameter, the lower petal hollow, enfolding the reſt till they expand, as in G. *pubeſcens*. It was firſt obſerved by Mr. John Bartram in 1760, on the borders of the Alatamaha river, in Georgia.

GORDYGONG, in *Geography*, a town of Hindooſtan, in Viſiapour; 22 miles N.E. of Poonah.

GORE, in *Heraldry*, denotes one of the regular abatements, uſed, according to Guillim, to denote a coward. It conſiſts of two arches or curve lines, drawn, one from the ſiniſter chief, the other from the ſiniſter baſe, and meeting in an acute angle in the middle of the feſſe-point.

GOREE, or GOEREE, in *Geography*, an iſland in the German ocean, near the mouth of the Meuſe, about 10 miles in circuit; two miles N. of Schowen. N. lat. 51° 49′. E. long.

E. long. 3° 50′.—Alſo, a ſea-port town of this iſland, near the E. coaſt, on a canal communicating with the Meuſe; formerly carrying on a conſiderable trade, but the harbour is now choaked with ſand; 6 miles W. of Helvoetſluys.

Goree, a ſmall iſland in the Atlantic, within cannon-ſhot of the coaſt of Africa, about two miles in circumference. The air is cool and temperate, being refreſhed by alternate breezes from the land and ſea. It is almoſt inacceſſible on account of its ſurrounding rocks; but it has two bays, and a fort with ſeveral new buildings conſtructed by a late director M. de St. Jean, who has alſo rendered it a very ſtrong place. By his perſevering aſſiduity, ſprings of freſh water have been diſcovered, and a variety of vegetables and fruit trees have been planted; ſo that the iſland, once barren and deſpicable, is now made one of the moſt ſafe, pleaſant, and important ſettlements in Africa. Goree was ceded to the Dutch in 1617 by a king of Cape Verd, and by them fortified. The Dutch were driven out by admiral Holmes in 1663, and the iſland was garriſoned by the Engliſh. It was two years after taken by De Ruyter, and its fortifications augmented by the Dutch; but in 1667 a French ſquadron compelled the Dutch to abandon Orange fort, and retire to fort Naſſau; but here, incapable of defending themſelves, they were obliged to ſurrender at diſcretion. Upon the arrival of M. du Caſſe, the iſland was formally taken poſſeſſion of in the name of the Senegal company, and a treaty was concluded with the king and negroes of the neighbouring country on the ſame conditions with thoſe by which the Dutch had poſſeſſed the iſland. The conqueſt was ſecured to the company by the treaty of Nimeguen. The French immediately repaired the forts, and changed their names, calling the lower fort "Vermandois," and the higher "St. Michael." In 1750 Goree was taken by the Engliſh. By the treaty of 1763 Goree and its dependencies were left to the French. In 1778 it was taken by the Engliſh. N. lat. 14° 40′. W. long. 17° 30′.

Goree, a ſmall iſland on the coaſt of Brazil, at the mouth of the Rio dos Reyes Magos. S. lat. 19° 10′.

GOREING, or Goring, is ſaid of a ſail when cut ſlanting, ſo that it is broader at the clew than at the earing, as all top-ſails and top-gallant-ſails are.

GOREL, a name or title given to the prince of Georgia. The gorel is always a Mahometan. The ſophy of Perſia obliges him to obſerve the religion of the Alcoran, in order to preſerve the dignity of gorel in his family.

GORE's Bay, in *Geography*, a bay on the S. W. coaſt of the iſland of Tavai-Poenammoo. S. lat. 43° 12′. W. long. 186° 36′.

Gore's *Iſland*, an iſland in the N. Pacific ocean, ſo named by captain Cook in the year 1778. This is a narrow iſland, particularly at the low necks of lands which form a junction between the hills; it is about 30 miles long from N.W. to S.E.; and it appeared barren and uninhabited. Some ſea-otters were ſeen. N. lat. 60° 40′. W. long. 172° 30′.

GORESBRIDGE, a ſmall poſt town of the county of Kilkenny, Ireland, 51 miles S.W. from Dublin, on the road to Waterford.

GOREY, a poſt town of the county of Wexford, Ireland, alſo called Newborough, which, before the Union, was repreſented in parliament. It is 45½ miles S. from Dublin, and 21 N. from Wexford.

Gorey-*Mountains* of Ireland, in the county of Donegal, near Raphoe.

GORGA, a town of Mingrelia, on the Black ſea; 30 miles S. of Anarghia.—Alſo, a river of Naples, which runs into the Liban, in Calabria Citra.

GORGE, in *Falconry*, is the uppermoſt bag or ſtomach of a hawk or falcon, being that which receives the food the firſt.

The gorge, *ingluvies*, is the ſame, in birds of prey, with what we call the *craw* or *crop*. When the bird is fed, he is ſaid to be *gorged*.

Gorge, in *Architecture*, denotes a ſort of concave moulding, wider but not ſo deep as a ſcotia; uſed chiefly in frames, chambranles, &c.

Gorge *of a Chimney*, is that part between the chambranle and the crowning of the mantle. Of this there are divers forms; ſtraight, perpendicular, in form of a bell, &c.

Gorge is ſometimes alſo uſed for a moulding that is concave in the upper part, and convex at bottom; more properly called gula and cymatium.

Gorge is alſo uſed for the neck of a column; more properly called colarin and gorgerin.

Gorge, in *Fortification*, the entrance of a *Baſtion*, or of a *Ravelin*, or other *Out-work*. See each article.

The Gorge *of a Baſtion* is what remains of the ſides of the polygon of a place, after retrenching the curtains; in which caſe it makes an angle in the centre of the baſtion.

In flat baſtions, the gorge is a right line on the curtain, reaching between the two flanks.

Gorge *of a Half moon*, or *Ravelin*, is the ſpace between the two ends of their faces next the place.

Gorge of the other out-works is the interval betwixt their ſides next the ditch.

All the gorges are to be made deſtitute of parapets; otherwiſe the beſiegers, having taken poſſeſſion of a work, might make uſe thereof to defend themſelves from the ſhot of the place: ſo that they are only fortified with paliſadoes, to prevent a ſurpriſe.

Gorge, *Half the Gorge*, *demi-gorge*, that part of the polygon between the flank and the centre of the baſtion.

GORGED, in *Heraldry*, is when a crown, coronet, or the like thing, is borne about the neck of a lion, a ſwan, &c. In that caſe they ſay, the lion or cygnet is gorged with a ducal coronet, &c.

Gorged is alſo uſed when the gorge or neck of a peacock, ſwan, or the like bird, is of a different colour or metal from the reſt.

Gorged, among *Farriers*, &c. ſignifies as much as ſwelled. In which ſenſe they ſay, the legs of an horſe are gorged; the paſtern-joint is gorged; you muſt walk him out, to diſgorge his ſhoulder.

Gorged, in *Rural Economy*, a term which is ſometimes applied to ſignify being *hoven* by freſh luxuriant green food, and relates to cattle, &c.

GORGERIN, a part of the ancient armour, being that which covered the throat or neck of a perſon armed at all points.

Gorgerin, or *Gorge*, in *Architecture*, the little freeze in the Doric capital, between the aſtragal, at the top of the ſhaft of the column, and the annulets.

Some call it *collarino*. Vitruvius gives it the name *hypotrachelium*.

GORGET, in *Military Affairs*, a piece of braſs or ſilver, worn by the officers of foot upon their breaſts when on duty. The gorget hangs round the neck by a ribband; they are ſometimes gilded, and have commonly ſome device engraved on them, as the ſovereign's, or even the colonel's coat of arms, creſt, or cypher.

Gorget, an inſtrument uſed in *Surgery*, for the purpoſe of cutting an opening into the bladder, ſo as to enable the operator to introduce the pair of forceps and extract the ſtone.

It is impoſſible to give the reader a proper notion of the form and manner of uſing the gorget, without preſenting him with engravings of the inſtrument, and entering into a deſcription of the operation of lithotomy. Hence, we muſt at preſent content ourſelves with referring to the ſurgical plates, and the article LITHOTOMY.

Beſides cutting gorgets, conſtructed for the above deſign, there are alſo blunt ones, intended to be introduced into the wound, when their concavity ſerves as a guide for the forceps into the bladder.

The employment of gorgets for the performance of lithotomy has been objected to by ſeveral eminent ſurgeons of the preſent day, particularly by Mr. John Bell of Edinburgh. (See his Principles of Surgery, vol. 2.) We have ſeen the operation moſt eaſily executed by means of a common ſcalpel. Mr. Aſtley Cooper uſes, inſtead of a gorget, a common ſcalpel with a beak, which glides along the groove of the ſtaff into the bladder. Several other knives and inſtruments have been at different times invented to ſuperſede the gorget. The principal ones will be repreſented in the ſurgical plates, and due notice will be taken of them in the article LITHOTOMY.

GORGIAS, ſurnamed *Leontinus*, in *Biography*, born at Leontium in Sicily, from whence he derived his ſecond name, was a celebrated orator and learned ſophiſt, who flouriſhed in the fifth century before the Chriſtian era. He was a diſciple of Empedocles, and is reckoned one of the earlieſt writers on the art of rhetoric. He is thought to have introduced numbers into proſe, treated of common places, and ſhewed the uſe of them for the invention of arguments. Hence Plato gave the name of Gorgias to his elegant dialogue on this ſubject, which is ſtill extant. He was ſo great an orator, that in public aſſemblies he would undertake to declaim extempore upon any ſubject propoſed to him. In the war between Syracuſe and Leontium, the citizens of the latter applied to the Athenians for ſuccour, and employed Gorgias and Tiſias as their ambaſſadors, the former of whom was peculiarly qualified to influence popular aſſemblies by his bold and perſuaſive eloquence. On their arrival at Athens about the year 427 B. C., Gorgias made an oration to the people on the grievances which their countrymen ſuffered from the people of Syracuſe, and the advantages which would accrue to them from ſending a powerful army into Sicily, by which he perſuaded them to ruſh headlong into a war, that proved in the end more fatal to them than any in which they had engaged. Afterwards he made a diſplay of his eloquence at the Olympic and Pythian games, on account of which a golden ſtatue was erected to his honour at Delphi. He is ſaid to have lived to the great age of 107 or 108.

GORGOGLIONE, in *Geography*, a town of Naples, in the Baſilicata; 15 miles E. of Venoſa.

GORGONA, an iſland of ſmall extent and of a circular form, in the Mediterranean, about 16 miles from the coaſt of Etruria. The mountains, ſays Sonnini, ſeem to be of the ſame nature with thoſe of the continent. This iſland is famous for the anchovy fiſhery on its coaſts. N. lat. 43° 22′. E. long. 9° 56′.—Alſo, an iſland in the Pacific ocean, about 18 miles from the coaſt of Peru, about 10 miles in circumference. N. lat. 3° 36′. W. long. 77° 52′.

GORGONEUM, Γοργονειον, in *Antiquity*, a kind of maſque uſed on the ancient theatre to repreſent hideous and frightful figures, in imitation of the Gorgons. Mem. Acad. Inſcript. tome v. p. 184.

GORGONIA, in *Zoology*, a genus of Zoophytes, the ſtem of which is coriaceous, woody, corky, horny, or ſomewhat bony, and in general flexible; the texture glaſſy, fibrous, or like ſtone, ſtriated, tapering, fixed at the baſe, which is dilated, and covered with vaſcular or cellular fleſh, or bark of a ſpongy and friable nature in a dried ſtate; the mouths or cells covering the ſurface of the ſtem and bearing polypes.

Theſe marine productions were regarded by the ancients as a claſs of plants, and deſcribed as ſuch by their botaniſts; nor was this idea, however remote from truth, exploded till ſo late a period as the eighteenth century, when the diſcoveries of Peyſſonel upon the nature of coral, publiſhed in 1727, and thoſe of Trembley on the hydra (or polype) about fourteen years after, contributed to demonſtrate, in a very explicit manner, that the gorgoniæ in common with other zoophytes (as theſe particular bodies are now denominated), do not appertain to the vegetable, but animal kingdom, or are at leaſt the fabrication and genuine habitations of animals.

Among the various obſervers of this curious order of animal productions, few, if any, have purſued their inveſtigations with greater diſcrimination and ſucceſs than profeſſor Pallas, or our own countryman Ellis, and his friend Dr. Solander; nor indeed can we heſitate to confeſs that our knowledge of the gorgonia tribe has been enlarged only in a very inconſiderable degree by any of the ſubſequent authors on this ſubject. The lateſt obſervations tend principally to confirm the accuracy of thoſe writers who had before aſſured us the gorgoniæ are the habitations of various kinds of polypiferous animals, each of which reſides in a diſtinct cell; that they lie in general dormant or contracted during winter, and, like the bloſſoms of plants, puſh forth buds, and expand in their proper ſeaſon, which is conſtantly in ſummer. The ſtem and branches of the gorgoniæ, which are moſt commonly of a ſomewhat horny and flexible nature, may be conſidered as the true ſkeleton of theſe neſts of habitations, being covered with a fleſhy or pulpy ſubſtance, the exterior ſurface of which is porous. Theſe pores are the mouths or openings of the cells in which the polypes are lodged, and it is the number, diſpoſition, and varied ſtructure of theſe, in addition to the general aſpect of the plant-like neſt of habitations, that conſtitute the moſt material differences by which the various ſpecies are diſtinguiſhed; the figure of the animal, when it can be aſcertained, forming the ſecondary or leaſt important character. It may be laſtly obſerved, that the gorgoniæ differ exceedingly in ſize, being from one to two, or perhaps three feet in height, while other ſpecies in deep bays, and ſimilar ſituations of the ſea, no leſs favourable to their growth and increaſe, attain to the gigantic height of ten or twelve feet, and from their number as well as magnitude; their remarkable ramoſe, and foliated or flabelliform appearance; interwoven ſtructure, and coral-like texture, form a conſpicuous portion of thoſe vaſt ſubmarine "groves of coral" that are ſometimes ſeen by navigators in the hotter regions of the globe.

Species.

LEPADIFERA. Dichotomous, with crowded, imbricated, reflected, campanulated florets. Müll. *Gorgonia reſeda*, Pallas. *Gorgonia reſediformis*, Gunner. *Reſeda marina*, Bell.

Native of the Norway ſeas, from eighteen inches to two feet high; fleſh pale, with whitiſh ſkin or ſcales; ſtem white, with a ſtony baſe and cartilaginous branches.

VERTICILLARIS. Pinnate, ramoſe, with alternate parallel ſubdiviſions, covered with verticillated incurved florets. Müll. Pallas, &c. *Sea-feather*, Ellis.

From two to three feet high; ſtem brittle and white, with flexible branches. Native of the Mediterranean and North ſeas.

Placomus. Branching both ways, with flexuous, and rarely uniting or anaſtomoſing branches, covered with conic florets. Linn. *Warted-ſea-fan,* Ellis. *Lithoxylon,* &c. Breyn.

Height two feet; ſtem erect, woody, and yellow, ſcarlet or reddiſh cinereous. Inhabits the Indian and European ſeas.

Mollis. Coriaceous, dichotomous, with perpendicular tubular florets. Pallas.

Native of the Mediterranean, and about eighteen inches in height, the colour brown violet; ſtem brown; branches long and ſlender.

Succinea. Round, amber-colour, dichotomous, rigid, the ſtem covered with tubercular gaping florets. Pallas.

A very rare ſpecies, the native place of which is unknown; it is only ſix inches high, the ſtem teſtaceous.

Americana. Branched and ſub-divided, the ſub-diviſions nearly oppoſite, compreſſed, with rows of polypiferous cells on each margin; fleſh yellowiſh, within pale purple; bone horny. Gmel. *Gorgonia pinnata,* Soland. and Ellis.

Native of the Weſt Indies; fleſh purpliſh or yellowiſh.

Exserta. Round, with a few alternate branches; florets alternate, eight-valved; fleſh covered with minute white ſcales; bone browniſh, horny. Soland.

Height two feet; branches long, ſlender, and white; polypes with eight feelers and exſerted. Inhabits the Weſt Indies.

Patula. Compreſſed, with flexuous ſub-pinnate branches, crimſon, with two rows of florets each ſide, each ſurrounded with a whitiſh ring: bone browniſh, horny. Soland.

Native of the Mediterranean.

Ceratophyta. Branched, with divaricate erect ſubdiviſions, each marked with two furrows; florets white, in irregular rows; fleſh purple; bone black and horny. *Gorgonia ceratophyta,* Soland. *Corallina fruticoſa purpurea,* C. Bauh. *Lithophyton, &c.* Geſn. *Corallina fruticoſa erectior,* Cateſby.

Found in the Mediterranean, Atlantic, and South American ſeas; height twelve inches; fleſh bright purple.

Juncea. Stem ſimple, round, and tapering both ways; bone duſky, horny; fleſh orange-colour, with two furrows; florets longiſh. Soland. &c. *Junci lapidei,* Plin. *Palmjuncue albus,* Rumpf.

Inhabits the ſhores of the American iſlands adhering to ſtones; height about three feet, and very flexible when alive.

Flammea. Compreſſed, branched, and ſub-pinnated; bone flat and horny; fleſh bright red, with minute florets. Soland. and Ellis.

A beautiful ſpecies, of a fiery red or flame-colour when recent; this kind inhabits the African coaſt, and appears to be found in moſt abundance near the Cape of Good Hope.

Umbraculum. Fan-ſhaped, and ſomewhat reticulated: branches numerous, divergent and round; fleſh reddiſh, warted or covered with florets. Soland. and Ellis.

Native of the Indian ſea; ſtem ſhort, riſing from a broad baſe, divided into about two or three branches, the ſmaller ones riſing from which are numerous, and ſo intimately connected as to form a kind of net-work.

Purpurea. Somewhat dichotomous, with divaricated ſlender branches; fleſh violet and ſub-verrucoſe. Pallas.

Round, ſmooth and blackiſh, with the extremities of the branches yellow. A South American ſpecies.

Sasappo. Sub-dichotomous, round, with divaricated ſlender branches; fleſh red, with numerous hairy florets. Pallas. *Accarbaar ſaſappo ſ. virga ſanguinea,* Rumpf.

About twelve inches in length, the texture horny, and colour black. The bernacle is frequently obſerved adhering to this ſpecies.

Palma. Flat, with numerous very long and ſimple diviſions; fleſh ſmooth, ſprinkled with ſimple pores. Pallas. *Chamæripha peregrina,* Cluſius.

Grows to the height of ſix feet, though more commonly not exceeding two or three feet; the ſubſtance horny, covered with a calcareous coating, and flexible. Inhabits the Indian ocean.

Radicata. Very much branched, and corky; with minute ſcattered pores, and many-cleft at the baſe. Pallas, Seba, &c.

Native of the African ſeas; ſub-dichotomous, grey, with branched trunk, and in ſubſtance reſembling cork.

Suberosa. Woody, very much branched, diffuſe, the branches compreſſed and grooved, and covered with ſubſtellated ſcattered pores. Pallas.

Height three feet; fleſh red, ſpongy; bone pale red and corky; branches long, round and erect. Found in the Indian and African ſeas.

Coralloides. Woody, erect, ſub-dichotomous, and variouſly formed; fleſh tuberous, with ſtellated tuberculated florets. Pallas. *Corallina lignum incruſtans,* Bocc.

Native of the Mediterranean; length one foot, very tough, pale grey, with yellow florets.

Elongata. Dichotomous, divaricated, with the fleſh red, and covered with papillous ſcattered ſub-imbricated pores. Gmel. &c.

Pale and brittle, with ſquare branches with pores at the angles; grows to the height of four feet, and inhabits the Atlantic.

Scirpea. Very ſimple, ſtraight, with a decompoſite leafy baſe, and ſoft tuberculated fleſh. Pallas.

Fuſcous, tapering towards the tip; the fleſh cinereous when dry; inhabits the Indian ſeas.

Setacea. Simple, rigid, with calcareous white ſub-tuberculated fleſh. Pallas. *Iſidis plocamum,* Mercat.

Native of the American ocean.

Viminalis. Very long, depreſſed, branched, with erect ſub-diviſions; fleſh yellow; florets ſeated along each margin of the branches, and rather prominent. Pallas. *Iſidis plocamum* II. &c. Mercat.

Height eight inches; branches long and ſlender; bone blackiſh and horny; florets white; the polype furniſhed with eight feelers or claws. Native of the Atlantic and Mediterranean.

Muricata. Round, with depreſſed ſub-divided branches; fleſh thick; pores cylindrical and ſpinous. Pallas, Ellis, &c. *Epicorallum,* &c. Petiv. *Lithophyton,* Tournef.

Native of the American iſlands; height from two to three feet; coriaceous, horny, with a whitiſh medullary nerve.

Verrucosa. Bifarious, with round, ſub-dichotomous flexuous branches; fleſh calcareous, pores whitiſh and prominent. Pallas, Ellis, &c. *Lithophyton marinum,* Geſn. *Corallina alba nodoſa,* C. Bauh. *Frutex marinus flabelliformis,* &c. Ray. *Erica marina,* &c. Petiv.

Inhabits the Weſt Indian, Mediterranean, and rarely the Britiſh ſeas, adhering by the broad baſe of the principal trunk to the rocks, and riſing to the height of twelve or fifteen inches, and ſometimes rather more, in a fan-like form; colour when dry greyiſh-white; bone of a texture between horn and wood.

ANTIPATHES. Shrubby, with erect, alternate panicled branches; bone with flexuous ſtriæ; fleſh thick and ſmooth; pores large and ſcattered. Pallas, &c. *Antipathes*, &c. Lobel. *Corallium nigrum Dioſcoridis*, ib. *Lithophyton nigrum arboreum*, Tournef. *Accabaar pohon*, Valent.

Grows to the height of two feet, and inhabits the Indian and Mediterranean ſeas. This is the black coral of the ſhops.

NOBILIS. Dichotomous, the branches ſomewhat tapering; fleſh red, ſlippery, and ſoft; the ſurface ſpeckled with numerous eight-valved, conic, and rather elevated, irregularly diſpoſed pores; bone bright red, ſtriated, and ſlightly punctured externally. Soland. and Ellis, &c. *Iſis nobilis*, Linn. Syſt. Nat. XII. *Madrepora rubra*, Linn. Syſt. Nat. X. *Iſis Pallas*. *Corallum rubrum*, Donat. *Red coral*, Ellis.

The bone of this ſpecies conſtitutes that beautiful and much eſteemed marine production, the red, or true coral of the jewellers. The coral is a general inhabitant of the Mediterranean, Adriatic, and Red ſeas, and appears to be no where more abundant than in the ſea about Marſeilles, Corſica, Sicily, and the coaſt of Africa, in the vicinity of Barbary, the coral fiſheries in thoſe parts being carried on with great ſpirit, and proving highly lucrative. From the obſervations of Donati, an author who has devoted much attention to this curious ſubject of enquiry, we underſtand that the fleſh or exterior coating of the coral is of a red colour, varying from bright to paler hues, the tint of which is uniformly leſs brilliant than that of the bone or coral itſelf. The moſt prevalent colour of the bone is red, exhibiting all the tranſitions from a pale roſe colour to fine ſcarlet, and ſometimes inclining to yellowiſh or fine ſaffron. The coral grows in a ſhrubby form, and not unfrequently in an inverted form, to the height of a foot or eighteen inches, which latter it rarely exceeds, nor is the circumference of the largeſt branches more than one inch. Externally the ſurface is ſtriated, more or leſs nodulous or warted, and the ſubſtance when broken appearing compoſed of a number of concentric layers. The coral of this ſpecies is equal in hardneſs and durability to the moſt compact marble, and theſe material qualities, in addition to its beautiful texture or grain, and colour, have contributed to render it valuable in the eſtimation of the world from the earlier ages, as we learn from Pliny, and other writers of remote antiquity. At this day the true coral bears a conſiderable price throughout the Eaſt as well as in Europe; its ſuppoſed medicinal virtues have, however, fewer votaries at preſent than formerly. The polypes, by which the cells are occupied, are furniſhed each with eight arms or tentacula, in the centre of which the mouth is ſituated; theſe arms are retractile, contract immediately on being touched; the cells or pores are filled with a white liquor, and the polypes are likewiſe white.

ANCEPS. Paniculated, ſub-dichotomous; ſtem and branches compreſſed; fleſh calcareous; margin porous. Gmel. Pallas, &c. *Sea willow*, Ellis. *Epicorallum virgulis alatis*, Petiv.

Inhabits the American, and ſome of the European ſeas: height nearly two feet; bone roundiſh, tapering to the ends, and violet when recent.

CRASSA. Round, dichotomous, with long, thick, divaricated, erect branches; fleſh thick, violet, with ſmall prominent, approximate, equidiſtant pores; bone dark brown and horny. Soland. and Ellis.

Native of the American ſeas.

PINNATA. Rather compreſſed and pinnated, with very ſimple compreſſed branches; fleſh red with oblong pores. Linn. *Palma pelagica*, Theophr. *Lithoxylon*, Breyn.

Grows to the height of from one to four feet; the texture horny and brown, the branches yellowiſh. Native of the African and North ſeas.

SANGUINOLENTA. Depreſſed, very ramoſe, and pinnated; fleſh yellow, with purple pores in double rows. Pallas. *Lithophytum flavum punctatum*, Tournef.

Native of the Atlantic and Mediterranean ſeas; height one foot.

VIOLACEA. Rather depreſſed, with pinnated branches; fleſh violet: nearly ſquare, with ſomewhat prominent pores. Pallas. *Quercus marina*, Theophr.

Inhabits the American ſeas, above a foot long, and horny.

SETOSA. Round and pinnated, with diffuſe branches; fleſh purpliſh. *Antipathes hirſutum*, Pon. *Lithophytum*, Tournef.

Grows to the height of two feet; very upright, and inhabits the Mediterranean and American ſeas.

PETECHIZANS. Sub-dichotomous, very much branched, with a yellow biſulcated fleſh covered with red pores. Pallas. Gmel. &c.

Native place unknown: bone horny, black, with amber-coloured ramifications.

PECTINATA. Round, with parallel aſcending ſimple branches; fleſh red, with gibbous ſcattered pores; bone white, hard, and brittle. Gmel.

Very rare, white, with red fleſh; found in the Indian ocean.

ABIENTINA. Ramoſe pinnated; fleſh yellow, with rows of purple florets each ſide; bone horny and yellowiſh. Soland. and Ellis.

Native of the African ſhores, and ſeldom exceeds a foot in height.

CALYCULATA. Dichotomous and ſubdivided, with erect thick ramifications covered with truncated papillæ; fleſh cinereous, within purpliſh; cells large and cup-ſhaped; bone dark brown and horny. Ellis.

Inhabits the American ſeas.

BRIAREUS. Subramoſe, round, thick; fleſh pale or whitiſh within, externally cinereous; bone compoſed of ſmall purple glaſſy needles, irregularly and cloſely diſpoſed longitudinally. Soland. and Ellis.

Cells large, prominent, numerous, and irregularly diſpoſed; the ſpecies inhabits the Weſt Indies.

VENTALINA. Reticulated; branches compreſſed externally at the ſides; bark red. Gmel. *Lithoxylon retiforme, &c.* Clifford Hort. *Gorgonia ventilabrum*, Pallas. *Flabella marina*, Rumpf.

Black or brown; the ſpecies inhabits the Indian ocean.

RETICULATUM. Reticulated, branches with very cloſe ſet round ramifications, and red tuberculated bark.

Very ponderous, of a grey colour, and inhabits the Indian ocean.

CLATHRUS. Reticulated, woody; with round ramifications; fleſh ſmooth with ſimple pores. Pallas.

Native place unknown; about eight or ten inches in height, pale, with a thin reddiſh-grey fleſh.

FLABELLUM. Reticulated; branches compreſſed internally; fleſh yellow. Gmel. *Gorgonia*, Pallas. *Flabellum veneris*, Ellis. *Frutex marinus*, Cluſius. *Frondipora*, Bonann. *Keratophytum reticulatum*, Brown. *Arbre de mer*, Rochef.

The bone is black, horny, and ſlightly ſtriated on the larger branches.

Found adhering to various ſubſtances, and varying in colour from yellow to purple: this ſpecies inhabits moſt ſeas.

GORGONIUM, in *Botany*, a name given by ſome authors to the common eryngium or eryngo, the roots of which we uſe candied.

GORGONS, in *Antiquity* and *Mythology*. Authors are not agreed in the account they give of the Gorgons. The poets repreſent them as three ſiſters, whoſe names were Stheno, Euryale, and Meduſa, the daughters of Phorcus by Ceto; the latter of whom was mortal; and having been deflowered by Neptune, was killed by Perſeus; the two former were ſubject neither to age nor death. They are deſcribed with wings on their ſhoulders, with ſerpents round their heads, their hands were of braſs, and their teeth of a prodigious ſize; ſo that they were objects of terror to mankind. Æſchylus, in his Prometheus, adds, that they had but one eye and one tooth among all the three, which they made uſe of one after the other, and that they killed men with a ſingle glance of the eye.

Pindar (Pyth. 12.) improves upon Æſchylus, and heightens the fable by theſe circumſtances, unknown to his predeceſſors. The firſt is, that the Gorgons turned thoſe into ſtone whom they looked upon, and that it was by this kind of death that Perſeus, in preſenting Meduſa's head, deſolated the iſland of Seriphus, whoſe inhabitants he petrified, together with their king. The ſecond is, that Minerva, who aided Perſeus while he was ſtruggling with Meduſa, being ſurpriſed with the melody of the Gorgons' ſighs, intermingled with the hiſſings of their ſerpents, felt certain charms in that mixed compoſition of doleful accents; and to renew the idea of the harmony, ſhe invented a flute in imitation of it, which ſhe imparted to men; and in alluſion to its firſt model ſhe called the various ſounds it produced "a Harmony with many heads." The third is, that Pegaſus, whom Heſiod repreſents as having taken flight to the manſion of the gods, was afterwards broke by Minerva, and given to Bellerophon, who mounted him to combat the Chimæra; but that hero having attempted to aſcend to heaven on the wings of that horſe, was thrown down to the earth, and Pegaſus placed among the ſtars. (Pindar's Ol. iii. Pyth. vii.) The Latin poets, though faithful copiers of the Greek ones, have yet loaded the fable of the Gorgons with new circumſtances. Homer had ſaid, that the Gorgon's head was engraved upon the tremendous Ægis of Minerva: Virgil adds, and upon her cuiraſs too, in the place which covered the goddeſs's breaſt:

> " ——— Ipſamque in pectore Divæ
> Gorgona defecto vertentem lumina collo." Æn. l. viii.

After the death of Meduſa, her ſiſters, according to Virgil, were appointed to keep the gate of the palace of Pluto:

> " Multaque præterea variarum monſtra ferarum—
> Gorgones, Harpeiæque——" Æn. l. vi.

Ovid of all the poets has more enlarged upon the fable of the Gorgons, and added ſeveral particulars which are only found in his Metamorphoſes, l. iv. and v.

Diodorus Siculus will have the Gorgons and Amazons to have been two warlike nations of women, who inhabited that part of Lybia which lay on the lake Tritonidis. The extermination of theſe female nations was not effected till Hercules undertook and performed it.

Pauſanias ſays, the Gorgons were the daughters of Phorbus, probably by miſtake for Phorcus; after whoſe death, Meduſa his daughter reigned over the people dwelling near the lake Tritonidis. The queen was paſſionately fond of hunting and war, ſo that ſhe laid the neighbouring countries quite waſte. At laſt, Perſeus having made war on them, and killed the queen herſelf, when he came to take a view of the field of battle, found the queen's corpſe ſo extremely beautiful, that he ordered her head to be cut off, which he carried with him to ſhow his countrymen, the Greeks, who could not behold it without being ſtruck with aſtoniſhment.

Others repreſent them as a kind of monſtrous women, covered with hair, who lived in woods and foreſts. Others, again, make them animals, reſembling wild ſheep, whoſe eyes had a poiſonous and fatal influence.

Xenophon of Lampſacus, who is followed by Pliny and Solinus, was of opinion, that the Gorgons were female ſavages, who inhabited the iſlands Gorgades. Hanno, the Carthaginian general, penetrated as far as theſe iſlands, where he found women, who, in ſwiftneſs, outran the flight of birds. Gerard Voſſius, in his "Origin and Progreſs of Idolatry," is perſuaded, that the fable of the Gorgons took its riſe from the relation of Hanno the Carthaginian general, above cited, from Xenophon of Lampſacus. Le Clerc, on the contrary, in his notes upon Heſiod, takes them for the mares of Lybia, which the Phœnicians in a voyage to Africa had taken away. Banier (Mythol. vol. iii.) is of opinion that the Gorgons dwelt in that part of Lybia, which was afterwards called Cyrenaicum; and that Phorcys, their father, had conquered Ithaca, which was not far from the coaſt of Africa, where he reſided. It is not incredible that this prince would employ his fleet in carrying on an advantageous trade, and that Polydectes, king of Seriphus, in order to get rid of Perſeus, gave him ſome ſhips for the purpoſe of pirating on the coaſts of Africa. Perſeus accordingly, thus equipped, ſailed from the iſle of Seriphus for the coaſt of Lybia, and having fallen in with the fleet of Phorcys, made himſelf maſter of ſome of his ſhips and a part of his riches. Theſe ſhips, it is ſaid, bore the names of Meduſa, Stheno, and Euryale. They were loaded with the teeth of elephants, the horns of fiſhes, and the eyes of hyænas, which Phorcys bartered for other goods. This, it is ſaid, is the myſtery of the tooth, horn, and eye, which the Gorgons borrowed by turns; that is, the ſhips, when arrived in the port, took each of them goods proper for the place to which they were bound. The other fictions that accompany this hiſtory, ſays the author now cited, will explain themſelves.

For a farther account of them, ſee Mem. Acad. Inſcript. vol. iv. p. 72, ſeq. See Medusæ *caput*.

GORGONZUOLO, in *Geography*, a town of Italy, in the department of the Olona; 10 miles N.E. of Milan.

GORGORA, an iſland of Abyſſinia, in the lake Dembea (which ſee), where a palace was built, which is the uſual reſidence of the emperor in winter.

GORHAM, a poſt town of America, in Cumberland county and ſtate of Maine, on the N.E. ſide of Saco river, 130 miles N.E. from Boſton: incorporated in 1764, and containing 2053 inhabitants.

GORIO, Anthony Francis, in *Biography*, a learned antiquary of the eighteenth century, a native of Florence, was author of the following works, *viz.* "Muſæum Florentinum," or a deſcription of the cabinet of the Grand Duke, eleven volumes folio, with a great number of plates: "Muſæum Etruſcum," three volumes, folio. "Muſæum Cortonenſe," folio. "Ancient Inſcriptions in the Towns of Tuſcany," three volumes folio.

GORITZ, or Gorz, in *Geography*, a country of Germany, in the circle of Auſtria; bounded to the N.E. and S. by the duchy of Carniola, and on the W. by the Venetian ſtates. The chief produce of the country conſiſts in wine and fruit, with ſome corn and ſilk; the horſes and oxen are ſew, but the goats are numerous. The language of the country is Sclavenian, and the religion Roman Catholic.

GORITZ, or *Goritia*, a town of Germany, ſituated in the above-mentioned country, and divided into Upper and Lower town; the former is ancient, ſeated on a mountain, and defended by a caſtle; the latter is ſituated on a plain on the river Liſonzo. Beſides the church, ſince the year 1784, not metropolitan, it has ſeven convents, nine chapels, and a college. In 1797 it was taken by the French: 20 miles N.N.W. of Trieſte. N. lat. 46° 5'. E. long. 13° 33'.

GORITZ, a town of Brandenburg, in the New Mark, ſeated on the Oder, formerly the metropolis of the circle of Lebus.

GORKA, a town of Hindooſtan, in Mewat; 12 miles S.S.W. of Cottilah.

GORKAH, a town of Aſia, ſituated in the N.E. part of the ſmall ſtate ſo called, on the borders of Napaul; 35 miles N.W. of Catmandu. N. lat. 28° 25'. E. long. 84° 36'. The country lies between the province of Oude and Thibet, and is governed by a raja dependent of Thibet.—Alſo, a town of the duchy of Warſaw; 40 miles S. of Poſen.

GORLÆUS, ABRAHAM, in *Biography*, a celebrated medalliſt, was born at Antwerp in 1549. He devoted himſelf entirely to the collection of ancient medals, ſeals, rings, and other curioſities. He died at Delft, where he ſpent the greateſt part of his life, in the year 1609. His works are entitled "Dactyliotheca ſeu Annulorum Sigillorumque e Ferro, Ære, Argento, atque Auro Promptuarium:" "Theſaurus Numiſmatum familiarum Rom.:" "Paralipomena Numiſmatum." His works are highly valued by thoſe who are addicted to theſe ſtudies. Moreri.

GORLITZ, in *Geography*, a town of Upper Luſatia, ſeated on the river Neiſſe, and the firſt town in the county with regard to ſize, population, and wealth. Within the walls it has three churches, and as many without. The principal trade is brewing, with woollen and linen manufactures. 50 miles E. of Dreſden. N. lat. 51° 9'. E. long. 15° 31'.

GOROCHOVETZ, a town of Ruſſia, in the government of Vladimir; 72 miles E. of Vladimir. N. lat. 56° 10'. E. long. 42° 34'.

GORODITSCHE, a town of Ruſſia, in the government of Penza; 32 miles E.S.E. of Penza. N. lat. 53° 20'. E. long. 46° 34'.—Alſo, a town in the government of Kiev, 112 miles S.E. of Kiev. N. lat. 49°. E. long. 32° 54'.—Alſo, a town in the government of Tobolſk, 20 miles E.S.E. of Eniſeiſk.

GORODNIA, a town of Ruſſia, in the government of Tver, on the Volga, 23 miles E. of Tver.

GORODNITZSK, a town of Ruſſia, in the government of Tchernigof, on the Snov; 32 miles N.N.E. of Tchernigof.

GORODOK, a town of Ruſſia, in the government of Poletſk; 36 miles E. of Poletſk. N. lat. 55° 36'. E. long. 29° 5'.

GORON, a town of France, in the department of Mayenne, and chief place of a canton, in the diſtrict of Mayenne; 9 miles N.W. of Mayenne. The place contains 1800, and the canton 12,733 inhabitants, on a territory of 200 kiliometres, in 11 communes.

GORONGO, a ſmall iſland in the Eaſt Indian ſea; 20 miles S. of Gilolo. S. lat. 1° 8'. E. long. 128° 33'.

GORONTALE, or GORONTANO, a town on the E. coaſt of the iſland of Celebes.

GORPETA, a town of Hindooſtan, in Berar; 24 miles W. of Chandor.

GORRIS, JOHN DE, in *Biography*, was born at Paris in the year 1505. He took the degree of doctor of phyſic in that city about 1540, and was appointed dean of the faculty in 1548. He is ſaid to have poſſeſſed both the learning and ſagacity requiſite to form an accompliſhed phyſician, and to have practiſed with great humanity and ſucceſs. His works contributed to ſupport this reputation. The greater part of them conſiſts of commentaries on different portions of the writings of Hippocrates, Galen, and Nicander. During the civil war, which was fatal to numerous men of letters, John de Gorris was ſtopped by a party of ſoldiers, when on his journey to Melun to viſit the biſhop of Paris, and the fright which he ſuſtained is ſaid to have deprived him of his reaſon. This occurred in 1561, and he lived many years in this deplorable condition, having died at Paris in 1577, at the age of 72.

His father, alſo John de Gorris, was a phyſician at Bourges, attained conſiderable eminence, and left two works, one on the general "practice of medicine," dated 1555; the other, a "collection of formulæ," 1560, both in Latin. Eloy Dict. Hiſt.

GORRITI, in *Geography*, a ſmall iſland in the river La Plata.

GORSA, a ſmall iſland near the S. coaſt of Cuba. N. lat. 21° 45'. W. long. 81° 25'.

GORSE. See FURZE and ULEX.

GORSIO, in *Geography*, a town of Sweden, in Helſingland; 30 miles W. of Hudwickſwall.

GORT, a poſt town of Ireland, in the county of Galway. It ſtands on an eminence, and is a dirty ſtraggling town, but can boaſt of a few good houſes. Adjoining to it are the ruins of a caſtle, and near it is Kilmacduagh, the ſee of a biſhop. Gort is 98 miles W. from Dublin.

GORTER, JOHN DE, in *Biography*, a phyſician, who, after having been a diſciple of the celebrated Boerhaave, became a diſtinguiſhed teacher of medicine at Harderwick, his native place; in conſequence of which he was elected a member of the academies of Peterſburg, Rome, and Haerlem, and obtained the title of phyſician to Elizabeth, empreſs of all the Ruſſias. He was the author of ſeveral works, which are written with excellent method, and contain many intereſting and original obſervations. He died on the 11th of September, 1762, at the age of 74.—His works, the titles of which are enumerated by Eloy, relate to phyſiological and practical ſubjects, as well as to the practice of the ancients. Eloy. Dict. Hiſt.

GORTERIA, in *Botany*, named by Linnæus after David De Gorter, profeſſor of phyſic and botany in the Dutch univerſity of Harderwick, author of ſeveral local Floras of that neighbourhood, and of Elementa Botanica. He died in 1783, aged 66. (Dryandr. Bibl. Banks. v. 5. 256.) Linn. Gen. 441. Schreb. 576. Willd. Sp. Pl. v. 3. 2265. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 254. Juſſ. 182. Gærtn. t. 171. Lamarck. Illuſtr. t. 702. (Gazania; Lamarck. Illuſtr. t. 702. Perſonaria; ibid. t. 716.) Claſs and order, *Syngeneſia Polygamia-fruſtranea*. Nat. Ord. *Compoſitæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* of one leaf, imbricated with ſpinous ſcales, the innermoſt gradually longer, ſtraight, briſtle-ſhaped, rigid. *Cor.* compound, radiated. Florets of the diſk numerous, perfect, with a funnel-ſhaped five-cleft corolla: thoſe of the radius fewer, female, with a ligulate lanceolate one. *Stam.* (in the perfect florets only) Filaments five, ſhort; anthers united into a cylindrical tube. *Piſt.* (of the perfect florets) Germen hairy; ſtyle thread-ſhaped, the length of its own little corolla; ſtigma cloven. In the female florets the germen is obſolete and abortive; ſtyle none; ſtigma none. *Peric.* none, except the calyx, falling off oſt entire. *Seeds* to the perfect florets only, ſolitary, roundiſh. Down ſimple or woolly. *Receptacle* naked.

Eſſ. Ch. Receptacle naked. Down ſimple or woolly. Florets of the radius ligulate. Calyx of one leaf, clothed with imbricated ſcales.

All the plants ranged under this genus are natives of the Cape of Good Hope. In the 2d edition of Linnæus's Species Plantarum, where it firſt appears, are five; *perſonata*, Jacq. Coll. v. 4. t. 21. f. 1; *rigens*, Curt. Mag. t. 90; *ſquarroſa*, *ciliaris*, and *fruticoſa*. The latter is the ſame plant as *G. aſteroides*, Linn. Suppl. 381, but different from *Atractylis oppoſitifolia*, under which it is quoted in Syſt. Veg. ed. 14. 730. To the above are added, in the Mantiſſa, p. 287, *G. ſetoſa*; and in the Supplementum ſix more, *herbacea*, *hiſpida*, *ſpinoſa*, *cernua*, *uniflora*, and *barbata*. Of theſe the *uniflora* is there ſuſpected, we believe juſtly, to be a mere variety of *rigens*.

The genus thus underſtood undoubtedly forms a very unnatural aſſemblage, Linnæus having chiefly conſidered the ſimple-leaved calyx, as Gærtner long ago remarked. Willdenow accordingly has but ſeven *Gorteriæ*, the *perſonata*, *rigens*, and *cernua* of Linnæus, with *diffuſa*, *integrifolia*, *pectinata*, and *ciliata* of Thunberg. Others are ſent to his genera of *Muſſinia*, whoſe receptacle is villous, and ſeed-down formed of ſimple hairs; and *Berckheya*, whoſe receptacle and ſeed-down are chaffy. Among the latter are the beautiful and truly wonderful *G. ciliaris*, and the *ſpinoſa*; the latter figured in Jacq. Hort. Schonbr. t. 372. This is doubtleſs a great improvement, but it ſeems to us that the genus muſt, after all, chiefly depend on *G. perſonata*, which is an annual plant, of no beauty, with many ſpreading *ſtems*, about a foot high. *Leaves* alternate, ſpatulate, revolute, pinnatifid or undivided; very white and cottony beneath; and green and briſtly, like the ſtems, above. *Flowers* ſolitary, terminal, ſmall, yellow, with numerous prominent ſpines to the calyx. The *ſeeds* are crowned with wool, but have no proper *pappus* or ſeed-down. The leaves of *G. rigens* bear ſome analogy with this, but the large orange bloſſoms, unarmed calyx, and long ſimple ſeed-down, urge the propriety of ſeparating it. The latter is Lamarck's *Gazania*, above quoted.

GORTYNA, or Gortyn, in *Ancient Geography*, an inland city of Crete, being, according to Strabo, near 90 furlongs diſtant from the African ſea, or that part of the Mediterranean which waſhed the ſouthern part of the iſland. Its origin is obſcure, ſome aſcribing it to Gortyn, the ſon of Rhadamanthus, and others to Taurus, who carried off Europa. In proceſs of time, however, it eclipſed all the other cities of Crete, eſpecially after the iſland was reduced by the Romans. Of its ancient ſplendour and magnificence we may form ſome judgment from its ruins, which are ſtill viſible about ſix miles from mount Ida; though many of them have been carried away by the Turks. In ancient times it was famous for the temples of Apollo, Diana, and Jupiter Hecatombæus, ſo called becauſe Menelaus there ſacrificed to Jupiter 100 oxen, when he received information of Helena's flight. Its walls were waſhed by the river Lethe. Theophraſtus, Varro, and Pliny ſpeak of a plane tree near Gortyna, which never ſhed its old leaves till new ones ſprouted forth.

GORTYNIA, a town of Greece, in the northern part of Macedonia.

GORUAH, in *Geography*, a town of Hindooſtan, in Bahar; 62 miles W.S.W. of Bahar.

GORY, a town of Georgia, in the province of Carduel, on the Kur; 45 miles W. of Teflis. N. lat. 41° 55′. E. long. 44° 30′.

GORZE, a town of France, in the department of the Moſelle, and chief place of a canton, in the diſtrict of Metz; 7 miles S.W. of Metz. N. lat. 49° 3′. E. long. 6° 4′. The place contains 1535, and the canton 14,278 inhabitants, on a territory of 220 kiliometres, in 31 communes.

GORZEGNO, a town of France, in the department of the Stura, on the Bormida; 13 miles S.E. of Alba. N. lat. 44° 38′. E. long. 8° 17′.

GORZKE, a town of the principality of Magdeburg; 34 miles E. of Magdeburg.

GOSAYPOUR, a town of Hindooſtan, in Allahabad; 13 miles N.W. of Jionpour.

GOSCHGOSCHUENK, a town of America, in the Delaware, conſiſting of three villages ſituated on the banks of the Ohio. Its name ſignifies "the habitation of owls," from the number of thoſe birds that reſort hither.

GOSCHUTZ, a town of Sileſia, in the principality of Oels; 25 miles N.N.E. of Breſlaw. N. lat. 51° 23′. E. long. 17° 30′.

GOSELINI, Julian, in *Biography*, an Italian writer, was born at Rome in 1525, where he purſued his maturer ſtudies in the houſe of the cardinal de Santa Fiora. When he was ſeventeen years of age he was taken into the ſervice of Ferdinand Gonzaga, then viceroy of Sicily. He accompanied that nobleman to Milan in 1546, and became his ſecretary, and was afterwards taken to the court of Spain, where he obtained the eſteem and favour of Philip II. Under the duke of Albuquerque he was impriſoned on a charge of conſpiracy againſt the life of Giambatiſta Monti. He vindicated his own cauſe, was releaſed, and admitted to public employment. He died in 1587, leaving behind him ſeveral works, that obtained for him high reputation: of theſe the principal are, "The Life of Ferdinand Gonzaga." "Three Conſpiracies, &c." "Rime," or a collection of poems, ſeveral times reprinted. "Diſcourſes." "Letters," &c. Bayle.

GOSFIELD, in *Geography*, a townſhip of Eſſex county, in Upper Canada, ſituated upon lake Erie.

GOSHAWK, in *Ornithology*, the Engliſh name of the Falco *palumbarius*; which ſee.

GOSHEN, in *Ancient Geography*, a territory of Egypt, ſituated between the Red ſea and the Nile, upon the borders of Canaan, not far from On or Hieropolis, which Joſeph obtained of Pharaoh for the reſidence of his father Jacob and family. This was a fertile ſpot of ground, and fit for cattle: and, therefore, as Joſephus tells us, Pharaoh kept his own in that diſtrict. It was alſo ſeparate from Egypt, and therefore fitteſt for Jacob and his family, which would be out of all danger of interfering with the Egyptians.

Goshen, in *Geography*, a townſhip of America, in the county of Hampſhire, and ſtate of Maſſachuſetts, between Cummington and Conway; 14 miles N. of Northampton; incorporated in 1781, and containing 724 inhabitants.—Alſo, a townſhip in Vermont, lying partly in Addiſon county, and partly in Caledonia, adjoining to Saliſbury on the weſt.—Alſo, a townſhip in Cheſter county, Pennſylvania, containing 966 inhabitants.—Alſo, a town in Litchfield county, Connecticut, famous for the production of excellent cheeſe, containing 1493 inhabitants; 7 miles N.W. of Litchfield.—Alſo, the moſt conſiderable town in Orange county, New York; about 58 miles N. of New York city. Its ſituation is pleaſant, and it contains about 60 or 70 compact houſes, an academy, court-houſe, gaol, and Preſbyterian church. The townſhip contains 2563 inhabitants.—Alſo, a place in London county, Virginia, where is a poſt-office; 37 miles from Waſhington.—Alſo, a town in Kennebeck county, Maine, containing 270 inhabitants.

Goshen *Creek*, a river of New Jerſey, which runs into Delaware bay. N. lat. 39° 10′. W. long. 74° 54′.

GOSHGOSBINK, a Moravian ſettlement in Pennſylvania, ſituated on Alleghany river, about 15 miles above fort Franklin.

GOSIR, a town of Arabia, in Hadramaut, near the coaſt; 75 miles S.W. of Keſchim.

GOSLING, a town of Auſtria; 12 miles S.E. of Bavarian Waidhoven.

GOSLINGS, the name given to young geeſe.

GOSPEL, a hiſtory of the life, actions, death, reſurrection, aſcenſion, and doctrine of Jeſus Chriſt.

The word is Saxon, and of the ſame import with the Latin term *evangelium*, or the Greek ευαγγελιον, which ſignifies *glad tidings*, or *good news*; the hiſtory of our Saviour being the beſt hiſtory ever publiſhed to mankind. This hiſtory is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John, who from thence are called Evangeliſts. (See each of theſe articles.) The Chriſtian church never acknowledged any more than theſe four goſpels as canonical; notwithſtanding which, ſeveral apocryphal goſpels are handed down to us, and others are entirely loſt.

We ſhall here ſubjoin the titles of ſome of the principal of theſe apocryphal goſpels, as we find them in Jones's Canon, and Lardner's Works, with remarks that will ſerve to enable us to diſtinguiſh them from our four goſpels, the authenticity of which is evinced under other articles in this work. (See BIBLE, CANON, and TESTAMENT.) Several of theſe ſpurious goſpels are mentioned in the decree, aſcribed to pope Gelaſius, in the council of Rome, A. D. 494, which pronounced them to be apocryphal. The goſpel of "Andrew the Apoſtle," is only mentioned in this decree. No fragments of it are extant, nor are there any teſtimonies concerning it. The goſpel of "Apelles" is not mentioned by any writer before Jerom, who places it among the apocryphal pieces of the New Teſtament. Apelles was a diſciple of Marcion, flouriſhed about the year of Chriſt 180, and is ſuppoſed to have formed this goſpel out of the true and genuine goſpels for the uſe of his followers at the cloſe of the ſecond century. The goſpel, "according to the twelve apoſtles," is mentioned by Origen, Ambroſe, and Jerom, but they unanimouſly concur in rejecting it, and in expreſsly aſſerting that the church receives only four goſpels. Jerom ſuppoſes this to have been the ſame with the goſpel according to the Nazarenes The goſpel "according to St. Barnabas" is not noticed by any of the Chriſtian writers of the firſt four centuries; nor do there ſeem to be any fragments extant, that unqueſtionably belong to it. Mr. Jones apprehends that this was merely ſome interpolated corrupted goſpel of St. Matthew. The goſpel of "Bartholomew" is mentioned by Jerom as apocryphal, and Jones, for reaſons which he alleges, inclines to think, that it was the ſame with the goſpel of St. Matthew, uſed by the Hebrews or Nazarenes. M. Daillè is of opinion that it was forged but a very little time before Gelaſius. The goſpel of "Baſilides" is named by Origen, Ambroſe, and Jerom, among the apocryphal books of the New Teſtament; but no fragments of it remain. The goſpel of "Cerinthus" is mentioned only by Epiphanius in connection with an expoſition of the firſt words of St. Luke's goſpel, as many other Chriſtian writers notice the apocryphal books; and it ſeems probable, from the ſimilarity of the opinions adopted by Cerinthus and the Ebionites, that the goſpel of Cerinthus and his followers was no other than the Ebionite or Nazarene goſpel, *i. e.* the goſpel of St. Matthew corrupted and interpolated, in Hebrew. The goſpel "according to the Egyptians," was one of the moſt celebrated apocryphal books, and ſuppoſed even by ſeveral modern critics to have been a faithful compoſure of ſome Catholic Chriſtians in Egypt, before either of the four canonical goſpels now received. The firſt Chriſtian writer who cites it is Clemens Alexandrinus, who, however, rejects it, though ſome have ſuppoſed that a paſſage in the ſecond epiſtle of Clemens Romanus to the Corinthians is taken from this goſpel. It is mentioned by Origen, Jerom, and Epiphanius among apocryphal books. Many modern writers, as Eraſmus, Grotius, Grabe, Mills, ſuppoſe, that it is referred to in the introduction to St. Luke's goſpel, and therefore that it was prior to his; and Dupin and F. Simon think, that though it is not of the ſame authority with the four canonical goſpels, it ought not to be rejected. Mr. Jones is of opinion, that it was compoſed by ſome very early heretics to ſupport their doctrines of celibacy and abſtemiouſneſs, and very probably by thoſe of Egypt; and Dr. Lardner thinks that it was not written before the third century. The goſpel of the "Ebionites" was either altogether, or very nearly, the goſpel of the Nazarenes. The goſpel of the "Encratites" has been mentioned by Fabricius and ſome others, but there is reaſon for doubting whether any goſpel was ever called by this name. The goſpel of "Eve" has been mentioned by ſeveral modern writers, but only by Epiphanius among the ancients; it was, without doubt, a forgery of the Gnoſtics. The goſpel of the "Hebrews" was the ſame with that of the Nazarenes. The goſpels of "Heſychius" were ſome interpolated copies of our received goſpels. The goſpel of "Judas Iſcariot" is mentioned by Irenæus and Epiphanius as peculiar to one of the moſt monſtrous and inconſiſtent ſects that ever aſſumed the Chriſtian name. The falſe goſpels of "Lucianus," who was a famous critic and martyr under Diocleſian, were, like thoſe laſt-mentioned, corrupted, interpolated copies of our preſent goſpels. The goſpel of "Matthias," of which there are now no remains, is mentioned by ſeveral of the moſt celebrated writers among the ancients, *viz.* Origen, Euſebius, Ambroſe, and Jerom; but they all repreſent it as apocryphal. The goſpel of "Marcion" is taken notice of by Tertullian and Epiphanius, but it appears to have been one of our own goſpels, mutilated and altered; probably that of St. Luke, from which he took away entirely the two firſt chapters, and many other parts, inſerting many things of his own, with a view to favour the opinions he had adopted. The goſpel of the "Nazarenes" or "Hebrews" is the moſt famous of all the ancient goſpels. Some have ſuppoſed that St. Paul refers to this goſpel, Gal. i. 6. It is cited by Ignatius, as ſome have ſuppoſed, by Clemens Alexandrinus, by Origen, by Euſebius, by Epiphanius, by Jerom; and it is mentioned by Bede, Sixtus Senenſis, Baronius, Caſaubon, Grotius, F. Simon, Dupin, Grabe, Toland, Nye, Richard Mill, Fabricius, Mangey, and other modern writers. However it is alleged, that this goſpel was never received by any primitive writer as canonical, nor was it cited or appealed to, as of any authority, by any one writer of the firſt four centuries; and moreover that it was compoſed out of St. Matthew's and the other authentic goſpels, with additions of ſome other things received by oral tradition. It is allowed, that it was an early compoſure, and Mr. Jones ſays, that it was undoubtedly extant in the beginning of the ſecond century, and ſeems to have been made by ſome converted Jews, to favour their notion of blending judaiſm and chriſtianity together. "As many miſtakes," ſays Dr. Lardner, "have been entertained about the "goſpel according to the Hebrews," it may not be unſeaſonable to obſerve here, that probably it was an Hebrew tranſlation of St. Matthew's original Greek goſpel, with additions from the other goſpels; to which poſſibly might be added ſome few particulars received by tradition from the early Jewiſh believers."

believers." (See Ebionites and Nazarenes.) This excellent writer elſewhere obſerves, it is not neceſſary for us to ſuppoſe, that the ancient fathers who mention other goſpels, thought, "that all, if any of thoſe goſpels, were written before St. Luke's, or that he ſpoke of them; for Baſilides and Apelles could not write goſpels before the ſecond century: and they might ſuppoſe, that ſeveral, if not all the others, mentioned by them, were written after St. Luke's. The meaning of what theſe ancient writers ſay is, that the church receives four goſpels only. There were many others. But to them may be applied the words of St. Luke; they only took in hand, or attempted. They did not perform, as Matthew, and Mark, and Luke, and John did. And they might expreſs themſelves in that manner concerning goſpels written after St. Luke's, as well as before it."

The goſpel of "Peter" has been taken notice of by many of the ancient writers, as Serapion, Tertullian, Origen, Euſebius, and Jerom. Some have ſuppoſed, that this was the goſpel of St. Mark, who was the companion of Peter, and wrote the goſpel now extant under his name. But there is reaſon for believing that the goſpel of Peter was different from that of St. Mark. It is not very certain by whom it was forged. Dr. Grabe, and after him, Dr. Mill, ſuppoſe it to have been made by Leucius, whom they reckon to have been a heretic of the ſecond century; but Leucius did not live till the latter end of the third, or the beginning of the fourth century; whereas this goſpel appears to have been extant in the ſecond century, as we may infer from the account of it by Serapion, who was biſhop of Antioch in the 11th year of the emperor Commodus, *i. e.* A.D. 190. Mr. Jones apprehends, that this goſpel was compoſed by thoſe ancient heretics in the ſecond century, called *Docetæ* (ſee that article); and he conjectures that the goſpel of Baſilides above-mentioned, was either wholly, or in a great meaſure, the ſame with this apocryphal goſpel under the name of Peter. The goſpel of "Perfection" was one of the numerous forgeries of the Gnoſtics, who pretended to a greater perfection in knowledge and virtue than all others, and hence took their name. (See Gnostics.) The goſpel of "Philip" was another forgery of the ſame perſons. The goſpel of "Scythianus" was compoſed by him who was the ſource and author of the Manichean hereſy. The goſpel of "Tatian" was no other but a harmony of four goſpels, or a ſort of epitome of the whole hiſtory contained in our four goſpels. The goſpel of "Thaddæus" is merely mentioned in the decree of pope Gelaſius. The goſpel of "Thomas," or the goſpel of the "Infancy of our Saviour," is mentioned by Origen, Euſebius, Cyril, Ambroſe, Athanaſius, and Jerom, and is unqueſtionably apocryphal; though this is different from the goſpel of Thomas, one of the followers of Manes, the head of the Manichees, for Origen, who mentions the former, lived a conſiderable time before the Manichean hereſy was divulged. The goſpel of "Truth" was a forgery of the Valentinians in the ſecond century. This is ſuppoſed by ſome to be the ſame with the goſpel of "Valentinus," but others are of opinion that he had a goſpel of his own, different from that called the goſpel of Truth uſed by his followers. For further particulars we refer to Jones's Canon and Lardner's Works.

GOSPINI, in *Geography*, a town of the iſland of Sardinia; 24 miles S. of Oriſtagni.

GOSPORT, is a ſea-port town of Hampſhire, England. In the time of king Henry VIII., when Leland viſited this part of the iſland, Goſport was only a poor village inhabited by fiſhermen, but it has gradually become a town of conſiderable extent and importance; and of late years has been regularly fortified on the land ſide by a line of baſtions, redoubts, counterſcarps, &c. that extends from Weovil to Stoke, or more properly, Alverſtoke lake. Within the works on the Weovil ſide, are the king's brewery and cooperage, with an immenſe range of ſtorehouſes for wine, malt, hops, &c. This place communicates with the ſea by means of a large baſin and canal, with extenſive quays, where veſſels of conſiderable burthen can take in their ſtores. Many ſmall ſloops belonging to Weovil are employed in the conveyance of wine, beer, and water, to the ſhips in the harbour. On the Weovil ſide are alſo the new barracks, an extenſive range of buildings, with every convenience for a great number of ſoldiers. Goſport, conſidered as a ſea-port, is handſomely built, and the police well regulated. The town is a chapelry to the neighbouring village of Alverſtoke: the chapel is a ſpacious edifice, ſtanding in a large well-planted cemetery, to the ſouth of the town; the interior is neat, and diſpoſed into a middle and two ſide aiſles. The work-houſe for the poor is a large, airy, and commodious building. Here are alſo ſeveral charity-ſchools; and ſome alms-houſes for diſtreſſed widows. The markets are held three days weekly, and are much frequented: fiſh and vegetables are ſold in great abundance; the latter being brought, not only from a conſiderable diſtance inland, but alſo from the Iſle of Wight. Two fairs are held annually. Several breweries are eſtabliſhed; and a very extenſive iron foundery, where numerous articles are manufactured for government. Goſport is 78 miles diſtant from London: the population of the pariſh of Alverſtoke, including the inhabitants of this town, was returned, under the act of 1801, at 11,295; the number of houſes being 1906. The connection between Goſport and Portſmouth is preſerved by numerous ferry-boats that ply acroſs the harbour, which in this place is about three quarters of a mile in width.

At a ſmall diſtance ſouth of Goſport, is the Royal Hoſpital of Haſler, built between the years 1746 and 1762, for the reception of ſick and wounded ſeamen, on the earneſt recommendation of the late earl of Sandwich. It is ſituated within 400 yards of the extremity of the point of land which bounds the weſt ſide of the entrance to Portſmouth harbour; and conſiſts of an extenſive front, and two wings, each compriſing two diſtinct ranges of buildings. In this hoſpital upwards of 2000 patients can be accommodated; the regular expence of the eſtabliſhment in ſalaries, &c. is above 5000*l.* annually.

Nearly a mile ſouth-weſt from Haſler hoſpital is Fort Monkton, a modern and regular fortification, exceedingly ſtrong, and defended by thirty-two pieces of heavy ordnance; to the weſtward, ranges a ſtrong redoubt; and this, together with the fort, effectually ſecures this part of the coaſt. On the ſhore, to the eaſtward, a high and maſſive ſtone wall has been erected, to preſerve the land from the ravages of the ſea.

Near the extremity of the neck of land which terminates the entrance of the harbour on the eaſt ſide, is the Block houſe, a very ſtrong fort, defended by a formidable battery. Beauties of England and Wales, vol. vi.

Gosport, formerly called *Appledore*, a fiſhing town of America, on Star iſland, belonging to Rockingham county, New Hampſhire, containing 85 inhabitants; about 12 miles E.S.E. of Piſcataqua harbour.

GOSS, in *Rural Economy*, a term occaſionally applied to the common whin in different places, and which is ſometimes written *gorſe*. See Furze.

GOSSAINGUNGE, in *Geography*, a town of Hindooſtan, in Oude; 15 miles S.E. of Lucknow.

GOSSAMER is the name of a fine filmy ſubſtance, like cobwebs, which is ſeen to float in the air, in clear days in autumn, and is more obſervable in ſtubble-fields, and upon furze and other low buſhes. This is probably formed by the flying ſpider, which, in traverſing the air for food, ſhoots out theſe threads from its anus, which are borne down by the dew, &c.

GOSSAMPINUS, a name given by Pliny and the ancients to a tree growing in the Eaſt Indies, which produced a ſort of cotton, the threads of which were too ſhort to be ſpun or carded; ſo that it ſerved only for the ſtuffings of beds and the like, for which it was very proper, being very light and ſoft. It was in ſome eſteem in medicine alſo, to recal the heat and ſpirits into parts to which it was applied. It is called by Piſo *arbor lanigera*, the wool-tree, and had its ancient name from the words *goſſipium*, cotton, and *pinus*, the pine-tree, being ſomewhat like the pine in external appearance, yet bearing a ſort of cotton.

GOSSE-ABDIAH, in *Geography*, a town of Nubia, on the Tacazé; 90 miles S. of Jalac.

GOSSEC, M. in *Biography*, a voluminous French muſical compoſer of the old ſchool, almoſt the only lineal deſcendant of Lulli and Rameau. He had force, fire, and knowledge; but his ſtyle was not that of the preſent day, either in Italy or Germany, nor could his friend, M. Laborde, perſuade us, that "true genius is in need of no ſchool or model. In whatever nation a man of genius may be born, he will make himſelf known, and not march with leſs firmneſs, though without a guide, in the road to glory. Celebrated ſchools cannot give genius, that is the boon of nature, and nature wants no ſchool." Eſſais ſur la Mus.

Unluckily, nature alone has never made an artiſt. A good painter, poet, or muſician, can never be made without education, ſtudy, and models. Ingenious works have been produced by dint of genius, but never faultleſs. The awkwardneſs of ſelf teaching will always appear; and taſte, elegance, facility, grace, and often learning, will be wanting to render them perfect.

GOSSEINS, in *Geography*, a town of Thibet, on the Dewah. N. lat. 30° 30′. E. long. 81° 24′.

GOSSELIES, a town of France, in the department of Jemmape, and chief place of a canton, in the diſtrict of Charleroy. The place contains 2872, and the canton 12,894 inhabitants, on a territory of 100 kiliometres, in 17 communes.

GOSSIPIUM. See GOSSYPIUM.

GOSSLAR, in *Geography*, a town of the kingdom of Weſtphalia, on the Goſe, which runs near this place into the Ockar. It was a free and imperial town, having on one ſide the biſhopric of Hildeſheim, and on the other the principality of Wolfenbuttle. It was founded in the year 922, by Henry the Fowler, and part of it re-built after being deſtroyed by fire in 1728. It has four pariſh churches, two chapels, and two Lutheran convents. Its principal trade ariſes from the mines of iron and lead in the Rammel mountain near it; 30 miles S. of Brunſwick. N. lat. 51° 55′. E. long. 10° 26′.

GOSSUM, a ſwelling of the thyroid gland. See BRONCHOCELE.

GOSSWEINSTEIN, or GOSSMANSTEIN, in *Geography*, a town of the biſhopric of Bamberg, on the Putlach, 20 miles E. S. E. of Bamberg. N. lat. 49° 45′. E. long. 11° 19′.

GOSSYPIUM, in *Botany*, the Cotton plant. The name is ſuppoſed by the learned to be of Egyptian origin, and if ſo, is akin to *Cotnemſegiar*, or *Gotnemſegiar*, the evident ſource of our word Cotton, which is given as the Egyptian appellation of the plant in Alpinus, de Plantis Ægypti, 71. Pliny makes it a Latin word, though the more common name he ſays is Xylon; the Greek ξυλον.—Linn. Gen. 355. Schreb. 468. Willd. Sp. Pl. v. 3. 803. Cavan. Diſſ. faſc. 6. 309. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 453. Juſſ. 274. Lamarck. Illuſtr. t. 586. Gærtn. t. 134. (Xylon; Tourn. t. 27.)—Claſs and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth double: the outer of one leaf, three-cleft, flattiſh, largeſt: inner of one leaf, cup-ſhaped, with five blunt notches. *Cor.* Petals five, inverſely heart-ſhaped, flat, ſpreading, attached to the tube of the ſtamens by their baſe. *Stam.* Filaments numerous, connected in their lower part into a tube, ſeparate and lax above, inſerted into the corolla; anthers kidney-ſhaped. *Piſt.* Germen ſuperior, roundiſh; ſtyle columnar, as long as the ſtamens; ſtigmas three or four, oblong, thickiſh. *Peric.* Capſule roundiſh, pointed, with three or four cells and as many valves, with contrary partitions. *Seeds* numerous, oval, fringed and enveloped with long wool.

Eſſ. Ch. Calyx double; the outer three-cleft. Capſule with three or four cells. Seeds enveloped in wool.

The ſpecies of Cotton, like thoſe of all plants cultivated from the moſt remote antiquity, in various countries, for economical purpoſes, are extremely difficult to define, and obſcured by numerous varieties.

Linnæus in Sp. Pl. ed. 1, defines three ſpecies only,

1. G. *herbaceum*. Camer. Epit. 203. Cavan. t. 164. f. 2, ſuppoſed to be a native of the Levant, Eaſt Indies, and Africa, and generally cultivated in thoſe countries for its produce.—Leaves five-lobed, pointed, with one gland beneath. Stem herbaceous, nearly ſmooth.—This is annual, with a buſhy, branched, often zig-zag *ſtem*, ſmooth or only ſlightly downy. *Leaves* cut half-way down into three principal, and two ſmaller lateral, pointed rounded lobes. The mid-rib bears one gland at its back, about half an inch from the ſtalk. *Flowers* yellow, purple at the baſe. *Capſule* the ſize of a walnut, enveloped in the calyx like a filberd.

2. G. *barbadenſe*, taken up from Plukenet, t. 188. f. 1. Leaves three-lobed, entire, with three glands beneath.—Suppoſed to be a native of Barbadoes. It is at leaſt one of thoſe cultivated in the Weſt Indies. The plant is in all its parts larger than the foregoing; lobes of the *leaves* not near ſo deep.

3. G. *arboreum*. Cavan. t. 165. Pluk. t. 188. f. 3. (Cudu-pariti; Rheede Hort. Mal. v. 1. 55. t. 31.)—Leaves palmate, five-lobed; lobes lanceolate. Stem ſhrubby.—Native of the Eaſt Indies in a ſandy ſoil. The woody perennial *ſtem*, and deep-cut long-lobed *leaves*, whoſe mid-rib bears one gland, diſtinguiſh this. The *flowers* are rediſh. The cotton is uſed in manufactures. Willdenow erroneouſly quotes Alpinus here.

His *Cotnemſegiar* is in the Plant. Ægypt. t. 71, not his Exot. t. 38, and does not agree with the Eaſt Indian plant.

To theſe is added in Sp. Pl. ed. 2. 975,

4. G. *hirſutum*. Cavan. t. 167. Leaves with three or five acute lobes. Stem branched, hairy.—The ſynonym of Tournefort is wrong.—This is ſaid to come from America. It appears to us a hairy variety of the firſt, for the gland on the mid-rib, which Linnæus thought an excluſive mark of *hirſutum*, is found in both.

What Linnæus intended by G. *religioſum*, Syſt. Nat. ed. 12. v. 2. 462, is rather doubtful. He defines it—"Leaves three-lobed, acute, with one gland beneath. Branches dotted with black."—We have an Eaſt Indian plant which anſwers to this definition, but it does not exactly agree with what he has marked *religioſum* in his own herbarium, which appears to us *barbadenſe*; though it may be what he had in his garden.

With the *latifolium* of Murray, Comm. Gott. for 1776. t. 1, we are unacquainted.—Cavanilles figures and deſcribes ſeveral more ſpecies, eſpecially G *vitifolium*, t. 166, a noble plant, from Commerſon's herbarium, gathered in the Mauritius.—Willdenow, adopting theſe, reckons ten ſpecies in all, but the ſynonyms of the whole genus require reviſion.

GOSTADT, Jottstadt, or *Joſephſtadt*, in *Geography*, a town of Saxony, in the circle of Erzgeberg; 23 miles S. of Chemnitz. N. lat. 50° 26′. E. long. 13° 2′.

GOSTIN, a town of the duchy of Warſaw; 48 miles N.N.W. of Rawa.

GOSYTULLA, a town of Bengal; 22 miles E. of Kiſhenagur.

GOTARA, a town of Hindooſtan, in Bahar; 57 miles S.S.W. of Patna.

GOTERON, a valley of Switzerland, in the canton of Friburgh, on the N.W. of the town of Friburgh, near the bridge leading to Bern, takes it name from the Goteron, a ſmall rivulet; it is extremely narrow, and above two miles in length, and is bounded on each ſide by overhanging rocks of ſandſtone. Vernet, the celebrated landſcape painter, ſtudied theſe rocks with great attention, and frequently declared that, excepting thoſe of Tivoli, he never ſaw any whoſe varying tints had a more pleaſing and harmonious effect. The valley contains ſeveral mills, an iron foundery, where the ore brought from Franche Comté is forged, and a manufacture of linen and cotton, eſtabliſhed by ſome merchants of Neuchatel, under the protection and encouragement of government.

GOTH, Stephen, in *Biography*, archbiſhop of Upſal, in Sweden, in the 16th century, concurred in the meaſures adopted by king John, to reſtore and re-eſtabliſh popery in that kingdom. With this view he ſanctioned a new liturgy, which, under the pretence of bringing the Lutheran church nearer to the ſimplicity of the earlier ages of the goſpel, artfully aſſimilated the doctrines and ceremonies of worſhip to thoſe of Rome, with the omiſſion of ſome particular forms and expreſſions which would have too plainly diſcloſed the object in view. This liturgy was ordered to be uſed in all the churches. The king's brother Charles, and the clergy within his juriſdiction, were alarmed at this attempt, and they ſo effectually rouſed the jealouſy and excited the fears of the people, and of the ſtates, that after repeated efforts to carry his point, which introduced great confuſion into the kingdom, and had nearly produced a civil war, the king was obliged to relinquiſh his ſcheme, and the liturgy was ſuppreſſed. It has long ſince become an object of curioſity among collectors, and is entitled "Liturgia Sueceanæ Eccleſiæ cum præfatione et notis Laurentii Upſalienſis Epiſcopi," 1576. Univer. Hiſt.

GOTHA, in *Geography*, a principality of Germany, in the circle of Upper Saxony, bounded on the N. by the electorate of Saxony, on the E. by the duchy of Weimar, on the S. by the county of Henneberg, and on the W. by the principality of Eiſenach. The duchy contains 12 towns, and more than 200 churches: it abounds in grain and fruit, and the ſouthern diviſion contains part of the foreſt of Thuringia, and ſome mine works. The ſtate conſiſts of three claſſes, *viz.* counts, nobility, and ſome barons, convoked by the prince. The reigning duke maintains a guard of 160 men, two regiments, each of which is compoſed of 800 men, and a corps of artillery. The chief rivers are the Leine and the Neiſſe.

The capital of the principality of the ſame name is ſeated on an eminence near the Leine, which ſupplies the town with water, conveyed by ſtone-canals, and is among the beſt and handſomeſt towns in Thuringia. It has an hoſpital for the ſoldiers, two ſchools for their children, and barracks, in which the military art is taught: it has likewiſe a foundery for cannon, balls, &c. two churches, a good academy, a houſe of correction, an hoſpital for widows, and another for orphans. The inhabitants carry on a conſiderable trade in wool and woollen manufactures, and beer; and they derive benefit, not only from the agriculture of the vicinity, but from the paſſengers that traverſe through it from Leipſick to Upper Germany. The reſidence of the duke, called Friedenſtein, ſtands on a hill above the town, and contains an armoury, a valuable library, a muſeum of natural curioſities, and an excellent cabinet of medals: 13 miles S.W. of Erfurt. N. lat. 50° 57′. E. long. 10° 40′.

Gotha, a river of Sweden, which iſſues from the ſouthern extremity of the lake Wenner, near Wennerſborg, and after a courſe of 70 miles, falls into the ſea near Gotheborg. In moſt places this river flows with a gentle current and in a narrow channel, and is navigable only in ſome parts of its courſe for ſmall craft of 20 tons burden. If it could be rendered navigable through its whole courſe, the Wenner lake might be joined with the German ocean; but as numerous ſhoals and cataracts intervene, the communication has been attempted by the Carlſgraf canal, the canal of Trolhætta, and the ſluices of Akerſtræm and Edet. About 10 miles from Gotheborg the river Gotha divides into three branches: two unite again after encircling a ſmall rocky iſland, crowned with the fort of Bohus, formerly deemed impregnable; the ſtream formed by the union of the two branches is called the Northern river, and falls into the ſea after a courſe of 10 miles. The third branch retains the original name of Gotha; and the ſpace included between the Northern river and the Gotha is named the iſland of Hiſingen.

GOTHARD, St., a town of Hungary, near which the Turks were defeated by the Chriſtians, in the year 1664; 21 miles W. of St. Crot.

Gothard, *St.* a chain of mountains of Swiſſerland, in the canton of Uri, the ſummit of which riſes above the ſea 9075 feet, though ſome have eſtimated its height to be much greater. The particular parts of this chain are called by different names; of which the principal are the Salla, Proſa, and Surecha, to the eaſt; the Feudo, the Patina, and the Locendro, to the weſt; to the north, the Urſino; and to the ſouth, the ridge of naked and piked rocks of the Val-Maggia. Of theſe, the Feudo is the higheſt. There are ſix paſtures on the neighbouring heights, on which are fed 200 cows, 150 goats, and 30 horſes. The river Teſino has three principal ſources in the chain of St. Gothard: the firſt is a ſpring near the foot of the Proſa, the ſecond is the lake of La Salla, in another part of the eaſtern chain, and the third is furniſhed by the ſnows of mount Feudo. Theſe three ſources uniting with another branch, that flows from the Furca, through the valley of Bedneto, form one great torrent, which takes its courſe towards the ſouth, enters the lake of Locerno, and traverſing part of the Milaneſe, falls into the Po. The ſource of the Reuſs is the lake of Locendro, an oblong piece of water, about three miles in circumference, ſtretching between the mountains of Patina and Locendro, and almoſt entirely ſupplied by the immenſe glaciers which crown the ſummit of the Locendro. The ſtream iſſuing from this lake ruſhes down the valley of St. Gothard, and joining in the vale of Urſenen, the two branches which come from the Furca on one ſide, and from the Griſon mountains on the other, flow towards the north into the lake of Lucern, and from thence throws itſelf into the Aar. The valley of St. Gothard is exceedingly dreary. It does not contain a ſingle ſhed, nor produce a ſingle tree; and the ſides of the mountains are barely ſprinkled with ſhort herbage.

Mount St. Gothard affords one of the beſt Alpine paſſages from Germany and Swiſſerland to Italy. The Romans were acquainted only with that over the Great Bernhard and Septimer. The Gothard was called by them ſometimes Adula, ſometimes the *High* and *Lepentine Alps*. The preſent road over this mountain begins at the village Hoſpital, in the Urſern valley, and terminates on the ſouth ſide, at Airolo: its breadth is from ten to twelve feet, and it is covered with large pieces of granite.

The firſt attempt of paſſing over the Gothard in a travelling carriage, was ſucceſsfully made in the month of July, 1775, by the late Mr. Greville, the gentleman to whoſe early exertion in collecting and in employing perſons well qualified to aſſiſt him, we owe the extenſive aſſemblage of minerals lately purchaſed by government for the Britiſh muſeum.

Though, in the high Gothard valley, the temperature is ſeldom below 19° of Reaumur, yet, on the N. ſide of the mountain, the climate is ſufficiently rough to make the growth of trees ceaſe at the height of 4566 feet. Among a vaſt number of plants common to the Alps in general, we find here, as peculiar to mount Gothard, the *Viola minima*, and *Campanula patula*.

But moſt intereſting is this mountain in regard to its mineral ſubſtances, and its geognoſtic ſtructure in general: for, reſpecting the former, it may be ſaid, that there is ſcarcely any where a tract of country known, that, within the ſame extent of ſpace, affords ſo conſiderable a variety of them. This is not the place for enumerating all theſe foſſils; we ſhould, however, not omit mentioning, that the *tremolite*, which has received its name from the valley of Tremola, is, according to Ebel, not found there, but deeper down the mountain, in the Leventine valley. See TREMOLITE.

The St. Gothard conſiſts entirely of primitive rocks, which, however, diſplay great variety in their mixture. On the N. ſide veined granite, gneiſs, mica-ſlate; in the plain of the rocky valley, where the Hoſpitium ſtands, granite of large grain, traverſed by beds of veined granite and mica-ſlate; from the ſummit downwards, on the S. ſide, maſſive granite of large and ſmall grain alternately, veined granite, mica-ſlate; in the Tremola valley, on the Fieudo and Soreſeia, hornblende-ſlate commences, mixed in ſome places with fine granular quartz, in others with feldſpar, and lower down with fine reddiſh-brown, dodecahedral garnets; over which beautiful rock the road winds, through the Pioſtella foreſt, down to Airolo. On the N. ſide, in the Urſern valley, among the juſt mentioned rocks, runs pot-ſtone on the S.S.E. part of the valley, and on the N.N.W. primitive lime-ſtone and clay-ſlate; while the S. ſide in the Leventine, Canaria, and Piora vallies, exhibits primitive lime-ſtone and gypſum.

All rocks of the Gothard are diſpoſed in ſtrata, having a direction from E.N.E. to W.S.W., and from N.E. to S.W. which is beſt obſerved between Hoſpital and Airolo, where the road makes a tranſverſal ſection, almoſt through the whole of the central chain. The regularity of the ſtratification of the granite is moſt ſtriking in the neighbourhood of the Rudunt bridge: the ſtrata are from three to four inches thick, and have their direction from N.E. to S.W. Likewiſe, on the Proſa and Fieudo, and ſouthward from Hoſpital down the valley of Tremola, the primitive lime-ſtone and gypſum, which paſs on the S. ſide of the mountain through the Leventine, Canaria, and Piora valleys, and the lime-ſtone, clay-ſlate, and pot-ſtone, ſeen on its N. ſide, in the Urſern valley, are the continuations of the ſame formations that range through the whole of the Pays de Vaud.

The ridges of mountains conſtituting the Gothard are exceedingly broken, and bear the marks of cauſes the moſt deſtructive; nor is it improbable that they were infinitely higher in ancient times, and that, at the period of the Romans, they were not unaptly called the *Higheſt Alps*. The upper rocky valley, where the Hoſpitium is ſituated, is covered with numberleſs pieces of rocks, which are all precipitated from the ſurrounding peaks. The great proportion of a ſmall grained granite, among the rocks of the Gothard, are the probable cauſes of this extraordinary devaſtation. The upper, nearly circular, rocky valley, was in former times completely ſhut on all ſides: the remains of the rocks that formerly filled the chaſms are ſtill diſtinctly ſeen on the N. ſide, near the bridge over the Rudunt, where the Reuſs forms a beautiful fall; and on the S. ſide, below the Hoſpitium, the rocks approach each other ſo cloſely, that the violent action which produced the preſent chaſms is ſufficiently evident. Before that revolution happened, it is highly probable that this conſiderable valley formed a deep lake; nor is it leſs ſo, that the Urſern-valley, before the Devil's mountain was broken through, and the upper Leventine valley, before the Platifer, near Dazeo Grande, was rent aſunder, repreſented deep ſeas of conſiderable extent.

GOTHEBORG, a town of Sweden, in Weſt Gothland, diſtinguiſhed by a commodious port, and ſtanding near the ſcite of Lodeſe, a town built by Guſtavus Vaſa, which, being endowed with ſingular privileges, ſoon became the great emporium for the trade of the weſtern provinces. Charles IX., when duke of Gothland, having, in 1604, laid the foundations of a new town in the iſland of Hiſingen, not far from Lodeſe, called it Gotheborg, in honour of his duchy. On his acceſſion to the throne, he erected in his new town a trading company; drew thither many foreigners, particularly the Dutch, to whom he allowed an exemption from all duties of export and import during twenty years; eſtabliſhed a corps of Engliſh and Scots troops, and granted to the Calviniſts the free exerciſe of their religion, the firſt place in Sweden where this toleration was permitted. By theſe means Gotheborg ſoon became a flouriſhing port, and, next to Stockholm, the moſt commercial town in Sweden. In 1611 it was reduced to aſhes by the Danes, and afterwards rebuilt in the reign of Guſtavus Adolphus on the preſent ſcite, and obtained a confirmation of its ancient rights, with a grant of ſeveral new privileges.

Gotheborg is built in a ſingular ſituation. At a ſmall diſtance from the ſea is a marſhy plain, not more than half a mile in breadth, watered by the rivers Gotha and Moldal, and almoſt incloſed with high ridges of bare and rugged rocks. Gotheborg ſtands partly on the ridges, and partly in the plain, and is divided into the upper and lower town. The latter is entirely level, interſected by ſeveral canals, and the houſes are conſtructed on piles: the upper part hangs on the declivities, and rows of buildings riſe one above the other like the ſeats of an amphitheatre. The whole is regularly fortified; and the circumference is near three miles, excluſive of the ſuburbs, called "Haga," which lie towards the harbour. The ſtreets are uniformly ſtraight; ſome few of the houſes are of brick, but moſt of them are conſtructed of wood, painted red. The harbour, formed by two chains of rocks, is about a quarter of a mile in breadth; and the entrance is defended by the fort of New Elfſborg, which ſtands on a ſmall rocky iſland, and contains a garriſon of 250 men.

A royal ſociety of ſciences and literature has been lately eſtabliſhed in this town, on the plan of that of Upſal. The acts, written in the Swediſh tongue, and printed in 8vo. contain diſquiſitions on various ſubjects, in the ſeveral branches of ſcience, natural hiſtory, antiquities, hiſtory, and polite letters. The population amounts to 20,000 perſons, in conſequence of an increaſe, occaſioned by the extenſion of its commerce, particularly on account of the Eaſt India company, and the ſucceſs of the herring fiſhery. The Eaſt India company was eſtabliſhed in 1731, and on account of the ice, which cloſes the port of Stockholm, in the gulf of Bothnia, at the proper ſeaſon of the departure of ſhips for the Eaſt Indies, the company carries on its commerce from Gotheborg, whoſe harbour, lying in the German ocean, is more open. In 1740, the herrings, which had not hitherto uſually approached the weſtern ſhore of Sweden, flocking in ſhoals, the inhabitants of Gotheborg eſtabliſhed a fiſhery, which has been very lucrative. The fiſhery begins in November, and though it continues ſcarcely three weeks, it ſupplies the fiſhermen of Gotheborg with not leſs than 600,000 barrels. Of theſe, 200,000 are ſalted, and train-oil is drawn from the remainder; fifteen barrels of herrings yielding one of oil, which is principally exported to Holland and Spain. One barrel of ſalt, procured from Spain, cures three barrels of herrings: the average exportation of ſalted herrings may be eſtimated at 150,000 barrels, and the inland conſumption of Sweden at 50,000. An Engliſh conſul and factory reſide at Gotheborg; and a chapel, with a regular chaplain, is appropriated for their uſe. The fortifications of Gotheborg are ſo weak, that in the year 1788 it muſt have fallen into the hands of the Danes, if foreign powers had not interfered. N. lat. 57° 40′. E. long. 11° 44′. Coxe's Travels in Sweden.

GOTHIC, or GOTHICK, ſomething that has a relation to the Goths, an ancient people, originally inhabiting that part of Sweden called Gothland; whence they ſpread themſelves over Greece, Dalmatia, Bulgaria, Italy, Spain, &c. See GOTHS.

GOTHIC *Architecture*, a term of reproach to denote one or more kinds of architecture which prevailed during the middle ages. It ſeems to have been invented by the reſtorers of the Grecian orders in Italy, about the middle of the 16th century, to ſignify every preceding ſpecies of European architecture not conformable to them, and it was imported in the ſame ſenſe into England by Mr. Evelyn and ſir Chriſtopher Wren, though the latter appears ſometimes to confine the term to the pointed ſtyle, in which particular he is followed by the greater part of late writers. Mr. Evelyn, quoted by ſir Chriſtopher Wren, in his "Parentalia," ſays: "Gothic architecture is a congeſtion of heavy, dark, melancholy, monkiſh piles." In the ſame ſenſe, ſir Chriſtopher himſelf, ſpeaking generally of what he terms Gothic architecture, calls it "Mountains of ſtone; vaſt, gigantic buildings, but not worthy the name of architecture. This we now call the Gothic manner: ſo the Italians called what was not after the Roman ſtyle." In oppoſition to the idea which this eminent architect here gives of the architecture in queſtion, he, in another part of his Parentalia, deſcribes the inventors of it as "ſetting up ſlender and miſ-ſhapen pillars, or rather bundles of ſtaves and other incongruous props, to ſupport ponderous arched roofs without entablature." In conformity with this latter notion of ſir Chriſtopher, Mr. Rious, a profeſſional writer, ſays: "Modern Gothic is diſtinguiſhed by the lightneſs of its work, the exceſſive boldneſs of its elevations and of its ſections, by the delicacy, profuſion, and extravagant fancy of its ornaments." The ſame confuſion of language, if not of ideas, prevails amongſt the admirers of the Gothic ſtyle, ſo called, as amongſt the declared foes of it. The late poet laureat, Thomas Warton, who has written a great deal on the ſubject, and who had planned a "Hiſtory of Gothic Architecture," ſpeaking of Saliſbury cathedral, expreſsly denies that it is in the Gothic ſtyle, while two other celebrated writers in the ſame line, the Rev. James Bentham and Capt. Groſs, as poſitively affirm that this cathedral is "entirely in the Gothic ſtyle." The perplexity and uncertainty of an ordinary reader muſt neceſſarily be encreaſed by the different ſenſes in which the terms, ancient architecture, modern architecture, Saxon architecture, Norman architecture, and Engliſh architecture, are now uſed by different writers. To clear up this confuſion, and to preſent diſtinct and clear ideas on theſe much agitated ſubjects, it ſeems beſt to treat them in an hiſtorical manner.

It is demonſtrable that the regular orders of Grecian architecture were upon the decline throughout the Roman empire after the reign of the Cæſars, and ſtill more ſo after that of Conſtantine the Great. A century later the Oſtrogoths over-ran and ſubdued Italy, the Viſigoths, Spain, the Huns, Germany, the Vandals, the Roman provinces of Africa, the Franks, France, and the Saxons, Britain. Theſe ſeveral barbarians deſtroyed innumerable monuments of architecture as well as of the other arts, but they none of them introduced a ſtyle of building different from that which they found practiſed in the conquered countries. They did not inſtruct the ancient inhabitants to build in a new manner; on the contrary, they learnt of them ſo much of the art as they actually acquired. But the art itſelf being vaſtly degraded in the fifth and ſixth centuries, and thoſe warlike hordes not being very apt ſcholars, no wonder their firſt ſtructures were executed in a rude and heavy ſtyle. Still nothing is more groundleſs than to ſpeak of Gothic architecture in the manner of Mr. Evelyn and ſir Chriſtopher Wren, as of a ſtyle of building invented or introduced by the Goths. The fact is, the heavy circular manner of building which prevailed throughout Chriſtendom, from the fall of the Roman empire, in the fifth century, down to the twelfth century, was the Roman, or, what is the ſame thing, the Grecian ſtyle, incorrectly and rudely executed. Amongſt us it is called the Saxon ſtyle, becauſe it prevailed during what is called the Saxon period or dynaſty in South Britain; but the firſt teachers and the models of it were both of them ſtrictly Roman.

On the firſt introduction of Chriſtianity amongſt our Saxon anceſtors, at the concluſion of the ſixth century, they conſecrated many of the exiſting Pagan temples to the Chriſtian worſhip, according to the inſtructions which they received to this effect from pope Gregory the Great, and they ran up other temporary oratories of wood or whattles, as we learn from Bede, and other original hiſtorians. Very ſoon, however, the ſame Roman miſſionaries, who converted them, taught them to build churches of ſtone after the Roman manner; for this denomination of it, *the Roman manner*, (*more Romano*,) is always mentioned by the aforeſaid hiſtorians. The firſt archbiſhop of the Northumbrians, Paulinus, who was a Roman monk, appears to have been the chief architect amongſt the Engliſh Saxons at the beginning of the ſeventh century. He built churches of ſtone at York, Lincoln, and other places. His next ſucceſſor but one, Wilfrid, was an Engliſhman, who not only equalled but greatly ſurpaſſed his maſter in architecture. For the churches which he built at Rippon and at Hexham were long celebrated for being the fineſt buildings of their kind north of the Alps: but then it is expreſsly recorded, both of him, and his rival in architecture, Benedict Biſcop, abbot and founder of the church and monaſtery of Weremouth, that they made different journies to Rome, and ſtudied the architecture of the church of St. Peter's and other churches there, and that they even hired workmen from thence to execute their works in England. Thus it evidently appears, that the ſtyle of architecture, which is call'ed the Saxon ſtyle, was not the invention of our anceſtors, but was imported from Italy in the ſeventh century; and it is equally evident, from various monuments, that the Italians in this and the ſubſequent ages built in the ſame heavy manner, and made uſe of the ſame members and ornaments, that the Engliſh Saxons did. Still the architecture of our anceſtors, previouſly to the conqueſt, though very heavy and rude, has been too much depretiated by many Engliſh writers. The Rev. Mr. Bentham, in his "Hiſtory of the Church of Ely," or rather the poet Gray, who drew up the architectural part of that work, refutes Somner, Staveley, and other authors, who deny that the Saxon builders made uſe of ſtone for their buildings, or knew how to turn an arch; but then this very writer fails to do them the juſtice due to them, where he ſignifies that they were unacquainted with the uſe of towers, bells, and tranſepts, previouſly to the tenth century. It would have been ſtrange if they had not imported theſe amongſt other eccleſiaſtical inventions from Italy during the preceding centuries; but we have otherwiſe ſufficient proofs that they had adopted each of them long before the tenth century.

During a great part of the ninth and tenth centuries, England and France were as much haraſſed by invaſions of the Northern barbarians, as their former inhabitants, the Gauls and Britons, had been in the fifth century, by the anceſtors of the now civilized Saxons and French. Theſe turbulent invaders, who were indifferently called Danes or Normans, were guilty of much greater devaſtation upon the exiſting religious monuments, at leaſt, than the Goths and Vandals had committed; becauſe the latter were Chriſtians, though Arians, when they over-ran the civilized world; whereas the Danes and Normans, when they invaded England and France, were perſecuting Pagans. So great was the dread of their violence throughout the laſt mentioned country, that the following petition was there added to the litany: "From the fury of the Normans, O Lord deliver us." In fact, the Almighty was pleaſed to deliver firſt France and then England, from the ſcourge which had ſo long and ſo ſorely afflicted them; but in a very different manner from what the Chriſtian inhabitants expected. Inſtead of witneſſing the extermination or ſubjugation of their barbarous enemies, they ſaw them bend their necks to the yoke of Chriſt, and become models of piety and morality to themſelves and the other Chriſtian nations. Such at leaſt was the caſe with the Northern men, who ſettled in that part of France, which from them has ſince been called Normandy. A laſting peace and tranquillity being, through this happy event, reſtored to the French provinces, its princes and nobles began to rebuild their demoliſhed churches, and to erect others with incredible diligence. But no people ſhewed ſo much zeal in this undertaking as the newly converted Normans. The reader will be convinced of this, when he is given to underſtand that William the Conqueror, during the few years that he reigned in Normandy, previouſly to his invaſion of England, built two noble churches and abbeys, and his nobles, not fewer than thirty-eight, each of them vieing with the reſt, to make his building the moſt magnificent and ſplendid. Such were the Normans, the braveſt, moſt induſtrious, and moſt religious people, and the moſt addicted, in particular, to eccleſiaſtical architecture of all Chriſtian people, when William, their prince, with the flower of his nobles, his army, and his eccleſiaſtics, came to ſettle in England ſoon after the middle of the eleventh century. It is to be obſerved, that the moſt celebrated ſchools of literature and the arts, and more particularly of architecture in Europe, at this period, were the abbeys of Bec and Caen in Normandy, the former of which produced thoſe three great architects, Lanfranc and Anſelm, ſucceſſively archbiſhops of Canterbury, and Gundulph, biſhop of Rocheſter. But indeed all the Norman prelates and abbots appear to have been able architects; for there was hardly a cathedral or abbey church in England which was not rebuilt by one or other of them, in the courſe of thirty or forty years after the conqueſt. The characters which they aimed at in theſe ſtructures were evidently the ſublime and beautiful. To produce the former effect, they built their churches as long and as lofty as poſſible; to produce the latter effect, they not only built in a much more neat and perfect manner than the Saxons had done, but alſo they made uſe of certain new invented ornaments in their ſtructures. Of theſe the moſt oſtenſible and ordinary was the arcade or ſeries of arches which, in one or other of its various forms, is to be met with in all the exiſting Norman churches. From the continued efforts of theſe indefatigable and ingenious architects, to make their churches as awful and as beautiful as poſſible, before the middle of the twelfth century, a new ſtyle of building was produced, called "the Pointed Style." It certainly appeared, for the firſt time, either in England or in France; nevertheleſs, the firſt aſcertained inſtance of it which has hitherto been produced, claims the honour of the invention for this country. But before we proceed to give a more particular account of the riſe and progreſs of this ſingular ſtyle of building, it will be proper to detail the various other ſyſtems which have been publiſhed reſpecting it.

It has been ſeen above, that Mr. Evelyn and ſir Chriſtopher Wren deſcribe the architecture of the middle ages, in general, whether circular or pointed, under the opprobrious term of Gothic, as being the real invention of the Goths and other barbarians. The former of theſe writers, as quoted with applauſe by the latter, ſays, in his "Parentalia:" "The Goths and Vandals having demoliſhed the Greek and Roman architecture, *introduced*, in its ſtead, a certain fantaſtical and licentious manner of building, which we have ſince called modern Gothic, of the greateſt induſtry and expenſive carving, full of fret and lamentable imagery, ſparing neither pains nor coſt."[*] We ſee that the writer here ſpeaks of the light pointed ornamental ſtyle of our anceſtors no leſs clearly than he does in another paſſage, quoted above, of the plain heavy circular ſtyle, called the Saxon; and that he ſuppoſes the former no leſs than the latter to have been really introduced into the countries, which had formed the Roman empire, by the Goths and Vandals, who ſubdued them. How little reaſon there is for aſcribing the Saxon ſtyle to theſe barbarians has been ſhewn above; and, with reſpect to the pointed ſtyle, it is ſufficient to obſerve that this appeared in no part of Chriſtendom before the twelfth century; whereas the Goths and Vandals committed whatever depredations on the monuments of Roman art, which they did commit, in the fifth century, and that their power was every where cruſhed, and their very name extinguiſhed in the courſe of the ſixth century, except, indeed, in Spain, where the name of Gothic remained attached to the reigning family, till the beginning of the eighth century and no longer. So groundleſs and abſurd, in every reſpect, is the term Gothic, as applied to pointed architecture!

At the ſame time that ſir Chriſtopher commends the ſyſtem of his friend Mr. Evelyn, he himſelf departs from it, ſince he prefers the word *Saracenic* to denote the pointed ſtyle. "What we now vulgarly call the Gothic," he ſays, "ought properly and truly to be named Saracenic architecture, refined by the Chriſtians, which firſt of all began in the Eaſt, after the

the fall of the Greek empire. The holy war gave the Chriſtians who had been there an idea of the Saracen works, which were afterwards imitated by them in the Weſt."

This ſyſtem concerning the pointed ſtyle, namely, that it originated with the Saracens, has, out of mere reſpect to the name of its author, ſir Chriſtopher Wren, been followed by biſhop Lowth, in his life of Wykeham, by Rious, by Warton, by Groſe, and, in ſhort, by the generality of modern writers who have had occaſion to enter upon the ſubject. In refutation, however, of this ſyſtem, we have to remark that the firſt, or Grand Cruſade, in which the conqueror's ſon, Robert, and many other Normans and Engliſhmen embarked, making part of above a million of perſons, who were engaged in it, began in 1096, and terminated by the capture of Jeruſalem in 1099. Now it is certain from hiſtory that the cathedrals of Exeter, Rocheſter, and Chicheſter, with many abbey churches, were built wholly in the circular ſtyle after the laſt-mentioned year. Amongſt theſe the inſtance which is moſt to the preſent purpoſe is that of Rocheſter cathedral, which was built by that greateſt architect of his age, Gundulph, formerly a monk of Bec abbey, then biſhop of Rocheſter, as well as the caſtle of that city, the chapel in the white tower of London, &c. without the leaſt mixture of the pointed ſtyle. The reaſon of this is, becauſe Gundulph had travelled through the Eaſt on a pilgrimage to Jeruſalem, a little before the cruſade took place, when he had an opportunity of ſurveying the churches and other buildings of thoſe countries at his leiſure. Again, it has been remarked by Groſe, Bentham, and other writers on the ſubject, that in all the deſcriptions and drawings of buildings in the Holy Land and other parts of the Eaſt, given us by Pocock, Norden, Shaw, Le Bruyn, &c. there is but one church, namely, that of St. John d'Acre, in the proper pointed ſtyle (which church the writer of this article has diſcovered to have been built by William, an Engliſhman, at the time when our Richard I. made himſelf maſter of that city); and that very rarely ſuch a thing as a pointed arch is repreſented as exiſting in thoſe countries. It is true a late writer, the Rev. Mr. Whittington, in his "Survey of the Eccleſiaſtical Antiquities of France," has propoſed to diſcover from theſe and other drawings pointed architecture in every part of the Eaſt, from the Euxine ſea to Egypt; but then it appears that he calls the mis-ſhapen obeliſks and minarets of the Mahomedan moſques pointed architecture. He has another argument for his aſſertion, namely, that "it is improbable the dark ages of the Weſt ſhould have given a model of architecture to the Eaſt." If there is any force in this argument, it would follow that the muſical ſcale of bells, optical glaſſes, the mariner's compaſs, gun-powder, and printing were diſcovered in the Eaſt inſtead of the Weſt, contrary to the known fact.

Mr. Murphy, to whom the admirers of pointed architecture are indebted for his elegant views of the church of Batalha in Portugal, conjectures that this ſtyle was borrowed from the pyramids, and that of courſe Egypt was its native ſoil. But in almoſt every country and age men have built their habitations with ſloping roofs to carry off the falling rain; hence they muſt have ſeen the figure of a triangle at the gable ends of them, no leſs than the Egyptians did in their pyramids. Denon's, Meyer's, and other views of ancient buildings in Egypt, are by no means favourable to Mr. Murphy's ſyſtem. There is indeed an ancient hall in the caſtle of Cairo, called Joſeph's Hall, which is a great deal in the pointed manner, and which is ſuppoſed by the vulgar to have been built by the patriarch of that name; but Niebuhr and lord Valentia give ſufficient reaſon to believe that it was built by Saladin, the enemy of our Richard I., whoſe true name was Joſeph. In fact, it is in the ſtyle of that period. According to this ſuppoſition, we are warranted in believing that this hall was the workmanſhip of Chriſtian priſoners, or fugitives, after the third cruſade. Mr. Murphy's theory is equally deſtitute of hiſtorical grounds and moral probability.

Biſhop Warburton, in his "Notes on Pope's Epiſtles," endeavours to unite together two of the above-mentioned refuted ſyſtems, that which derives pointed architecture from the Northern Goths, and that which brings it from the Eaſtern Saracens, at the ſame time that he aſſigns the weſtern peninſula of Europe for the real place of its birth. The following is an abridgment of his account. "When the Goths had conquered Spain, and the religion of the old (Chriſtian) inhabitants had inflamed their piety, they ſtruck out a new ſpecies of architecture unknown to Greece and Rome. For this northern people having been accuſtomed, during the gloom of Paganiſm, to worſhip the Deity in groves, when their new religion required covered edifices, they ingeniouſly projected to make them reſemble groves; at once indulging their old prejudices, and providing for their preſent conveniences by a cool receptacle in a ſultry climate, with the aſſiſtance of Saracen architects, whoſe exotic ſtyle of building ſuited their purpoſe." All this is a mere revery. The Goths and Vandals entered Spain in the year 409. They did not, however, acquire there a new religion from the old inhabitants, for they were already Chriſtians, and habituated to the uſe of churches. On the other hand, the Mooriſh Saracens did not enter Spain till three hundred years afterwards, namely, till the year 712, when having cooped up the Chriſtians in the mountains of Aſturias, there continued ever afterwards the moſt relentleſs warfare between the two people. It is impoſſible to conceive more monſtrous ideas than that the Chriſtian Goths ſhould have brought with them into Spain a partiality for the Pagan worſhip which they had practiſed in the foreſts of Germany, and that they ſhould have retained it for the ſpace of three hundred years afterwards, till they had the means of employing their implacable enemies, the Mahomedan Moors, to build Chriſtian churches for their uſe; and that when this was effected, they ſhould have kept the ſecret of pointed architecture to themſelves for the ſpace of 400 years longer! Were all this poſſible, or were it a fact that this ſtyle had been imported into our country from any other, where it had been practiſed for a conſiderable time before, it would have made its appearance amongſt us all at once, with its ſeveral ſtriking characters; contrary to what we actually ſee was the fact. After all, if the aiſle of an ancient cathedral reſembles an avenue of trees in ſome reſpects, it differs from it in many others, which are obvious to the ſight.

Having followed different guides, north, eaſt, and weſt, in ſearch of the original pointed architecture, we have latterly been invited by an ingenious artiſt to accompany him to the ſouth, namely, into Italy, the cradle of modern arts, with a promiſe that he will there point out to us much earlier ſpecimens of this ſtyle than are to be met with in this northern climate. In the year 1805 Mr. Smirke jun., then returned from Italy, laid before the Society of Antiquaries a certain drawing, ſince engraved in the "Archæologia," vol. xv., of the dreſſings of a window belonging to the cathedral of Meſſina, in the richeſt ſtyle of the third pointed order, being ſuch as we have no example of in this country before the middle of the 15th century. Theſe dreſſings he would have us believe are coeval with the cathedral itſelf, which was built by the Norman chieftain Roger, earl of Sicily, in the eleventh century. He preſented another drawing, publiſhed by the ſociety as aforeſaid, which appeared to be much more for his purpoſe, becauſe of the known dates of the original. This drawing repreſents a portion of the outſide of the baptiſtery of the cathedral church at Piſa, which baptiſtery was certainly built by Dioti Salvi in 1152. The drawing exhibits what we ſhould call Roman and Saxon work, with intermixed crocketted pediments and pinnacles, ſuch as we were unacquainted with for more than a hundred years afterwards. Laſtly, this gentleman ſhewed a view of the cloiſter of Campo Santo, adjoining the laſt mentioned cathedral, built in 1278. Here we ſee the richeſt tracery mullions under ſemi-circular arches, the whole of which he conſidered as being the ſame original work. Theſe ſpecimens gained many converts to his ſyſtem, that of Italy being the parent country of pointed architecture.

But there is no error which we have ſo much to guard againſt in ſtudying architectural antiquity as the confounding of ſubſequent alterations with the original work. There are few adepts in this ſcience who would not ſtart at the firſt ſight of Mr. Smirke's drawings, and who would not pronounce the works they repreſent as an incongruous mixture of the architecture of different ages; but it was reſerved for ſir Henry Englefield's profound knowledge of the ſubject and critical acumen to detect and exhibit in detail the pointed enrichments with which later architects had decorated the plain circular works of their predeceſſors. To the juſtice of this learned antiquary's remarks the accurate hiſtory of the cathedral of Piſa, written by Martini a canon of that church, bears ample teſtimony. In a word, the very ſpecimens which Mr. Smirke has produced in favour of Italy's claim to the invention of pointed architecture, as well as all the other buildings, tombs, and altars at Rome, and in every other part of Italy, demonſtrate its great inferiority both in date and in execution, to England, France, and Germany, with reſpect to this particular ſtyle.

Allied, in one reſpect to the ſyſtem of biſhop Warburton, is that of ſir James Hall, bart., who, in "An Eſſay on Gothic Architecture," now publiſhed, endeavours to ſhew that the pointed ſtyle was borrowed from the idea of upright poſts ſurrounded with oſiers, the heads of which are to meet like thoſe of trees in an avenue. But the utmoſt that the ingenious baronet proves is that baſket-work may be made to reſemble pointed architecture, not that pointed architecture was borrowed from exiſting models of baſket-work. Lord Orford, heretofore ſir Horace Walpole, in his "Obſervations on Engliſh Architecture," ſays, that the architecture in queſtion was copied from ſhrine-work; juſt as if the making of boxes preceded the building of houſes! After all, this is only placing the tortoiſe under the elephant; for where did artiſts learn to faſhion their ſhrines in the pointed ſtyle! Laſtly, Mr. Payne Knight derives this ſtyle from all the three parts of the world, heretofore known, Europe, Aſia and Africa, where he decides, in his "Principles of Taſte," that "the ſtyle of architecture which we call cathedral or monaſtic, is manifeſtly a corruption of the ſacred architecture of the Greeks or Romans, by a mixture of the Mooriſh or Saracenic, which is formed out of a combination of the Egyptian, Perſian, and Hindoo."

But why ſhould we wander into every remote corner of the world, and even into the regions of fancy in ſearch of an invention which belongs to our own climate? And for what purpoſe ſhould we take ſo much pains to prove a plant to be an imported exotic which wo have ſeen ſprouting up, and attaining its full growth in our own garden? Let us now go back to the point from which we ſtarted in purſuit of various falſe ſyſtems. We have ſeen above that the greateſt people, without diſpute, of the eleventh and twelfth centuries, namely, the Normans, the conquerors of England, France, Italy, Sicily, and various regions in the Eaſt, were at the ſame time a moſt induſtrious and ingenious people, and poſſeſſed of the moſt ardent paſſion for eccleſiaſtical architecture of any people we read of, and that they vied with each other in the grandeur and beauty of their reſpective ſtructures. To produce the effect of grandeur, as it has been before obſerved, they gave the greateſt poſſible length and height to their churches; for that of beauty they deviſed ſeveral architectural ornaments; the moſt common of which was the arcade or ſeries of ſmall round arches, which appear on ſome part or other of all their churches built in this country ſubſequent to their conqueſt of it, and which ſometimes cover the whole of them over; as we ſee on the outſide of St. Botolph's priory, and St. Oſyth's abbey in Eſſex, and in the baſement ſtory of the inſide of Durham cathedral. Theſe arcades the architects diverſified in a great variety of ways, as may be ſeen upon the tower of St. Auguſtine's monaſtery in Canterbury, built by the Norman abbot Scoltandus in 1080. One of the varieties conſiſted in making the circular arches interſect each other. The portion thus interſected formed a new kind of arch, more graceful in its appearance, and far better calculated to give an idea of height than the round one, which, however, had hitherto been adopted by all nations, whether Egyptians, Greeks, Romans, or Saxons. In fact, every one muſt be ſenſible that a pyramid or obeliſk, from its aſpiring form, appears to be taller than a ſemicircular arch, the diameter of which is equal in height to it. Theſe plain and interſecting arcades were ſometimes irregularly intermixed, as in Carilepho's and Flambard's work on the north ſide of Durham cathedral; and ſometimes placed in alternate rows, as in that of Remigius on the façade of his church at Lincoln. The pointed arch thus formed appeared firſt in mere *baſſo relievo*, as in the above mentioned inſtances, amongſt ſeveral others; but ſoon it was likewiſe ſeen in *alto relievo* over niches and receſſes, in the walls of churches, as in the remains of archbiſhop Lanfranc's work in Canterbury cathedral, and in the abbey churches of Glaſtonbury and Rumſey. It is probable that ſome of the firſt, if not quite the firſt open arches in the pointed ſtyle now exiſting, are the twenty windows in the interſected portions of ſuch croſſing arches in the choir of St. Croſs near Wincheſter, made by that great encourager of the arts, and particularly of architecture, biſhop Henry de Blois, king Stephen's brother. The date of this work is 1132, according to Godwin, Groſe, and others, or elſe 1130, according to biſhop Lowth, who had examined the records of this foundation, and Rudborne, the monk of Wincheſter, in his "Hiſtoria Major Wintonienſis." Moſt probably the choir was begun in the former year, and finiſhed in the latter. As the prelate proceeded in his work, from the choir to the tranſept and tower of his church, he made ſeveral other pointed arches without any interſecting circles over them, notwithſtanding the greater part of his work, as ſtill appears, was the circular Saxon. In 1138, as we are aſſured by the above-mentioned monk of Wincheſter, and another monk who wrote the "Annales Wintonienſes," biſhop De Blois rebuilt his epiſcopal manſion of Farnham in Surrey, where his ſucceſſors ſtill ordinarily reſide. Now in the ancient part of this building, we ſee at the preſent day pointed arches reſting upon circular Saxon columns, juſt as we do at St. Croſs; and no architectural critic, with theſe documents before him, will heſitate a moment in pronouncing them part of the work in queſtion, executed by De Blois in 1138. As the ſame prelate reſtored the abbatial church at Rumſey, where his niece Mary was a nun, and as he himſelf had been abbot of Glaſtonbury, before he was biſhop of Wincheſter, we may ſafely attribute the pointed arches, intermixed with the circular ones in theſe two ſtructures, to his direction, ſome time in the latter end of the reign of his couſin Henry I.

After all, it would be raſh to pronounce abſolutely that biſhop De Blois of Wincheſter was the author of pointed architecture, ſince we have convincing evidence, that churches were built by other architects about this period, in the ſame mixed ſtyle of pointed and circular work. We muſt, however, incidentally obſerve, that before the concluſion of this twelfth century, the circular ſtyle was entirely laid aſide, as well with reſpect to columns as to arches. We have evidence, for example, in the annals both of St. Wurburg's abbey Cheſter, and of Peterborough abbey, quoted by Dugdale, that Bildwas abbey in Shropſhire, where the ſeven pointed arches of the nave, ſurmounted by ſmall circular arches, in the upper ſtory, are ſtill ſeen, was founded either in 1136 or 1139; probably it was begun in the former year, and finiſhed in the latter. We might argue in the ſame manner from the dates and actual ſtate of Kirkſtal abbey, Lantony abbey, and ſeveral other ancient ſtructures. If we may give implicit credit to the teſtimony and the plates of captain Groſe, the Scotch architects were not long in adopting the ſtyle of their Engliſh neighbours. It is remarkable that the eccleſiaſtical buildings erected by David king of Scotland, and his nobles, before he came into England in order to command the armies of his niece, the empreſs Maud, were purely in the Saxon ſtyle; whereas thoſe founded there, after that event, preſent the ſame mixture of circular and pointed architecture which prevailed at that period in England.

A late writer, the Rev. Mr. Whittington, whoſe profeſſed object it was to transfer the credit of the diſcovery in queſtion from the Norman Engliſh and Engliſh to the French, which credit the latter ſeem diſpoſed, from traditionary accounts, to attribute to our countrymen, has aſſerted that examples of pointed arches, of a more ancient date than any exiſting in England, are to be met with at the abbey church of St. Denis near Paris, which church was finiſhed in 1144. It appears, however, that this writer was unacquainted with the hiſtorical evidence on which the above-mentioned early inſtances of the pointed arch in England reſt, and that he was even at a loſs to determine which of the works at St. Denis really belonged to the period he has aſſigned. If we examine the pointed windows of this abbey, exhibiting different tranſactions of the firſt cruſade in Montfaucon's "Monarchie Françoiſe," which windows are ſaid by this great antiquary to have been executed by abbot Suger in 1140, we ſhall not find the appearance of a pointed arch in any one of them. It may be added, that in the famous tapeſtry of Bayeux, repreſenting the conqueſt of England, and ſaid to have been wrought by the conquerer's mother, there is no appearance either of a pointed, or ſo much as of an interſected arch, in the ſeveral churches, ſhrines, and other architectural works there diſplayed. In a word, throughout the whole of Montfaucon's plates, we every where find the French pointed architecture much inferior to that of a correſponding date in our own country.

To return to the ſubject of interſecting arches: we obſerve theſe ſometimes to conſiſt of plain ſemicircles croſſing each other, as on the outſide of the ſouth tranſept of Walkelyn's work at Wincheſter, and on the north tranſept of Warlewaſt's work at Exeter, forming in the interſections ſimple pointed arches; and ſometimes we remark that the interſections reſt upon pillars, each of them being ſurmounted with a capital, or at leaſt with an abacus, as on the north tranſept of Durham, and the weſt front of Lincoln cathedrals. In the latter caſe, we have the appearance of pointed arches with lateral points, or cuſps within the heads of them, as ſir James Hall has very aptly termed them. This addition to the pointed arch was occaſionally uſed in the firſt period or order of pointed architecture, but afterwards it became univerſal. The addition of another cuſp on each ſide of the pointed arch turned its trefoil head into a cinque foil. In like manner, four of theſe cuſps being placed at equal diſtances within that circle or "L'Œil de Bœuf," which the Roman and Saxon architects had been in the habit of placing in the tympanum of their pediments, turned it into an elegant quatrefoil or croſs. By means of additional cuſps, and circles within circles, the Catharine wheel, or Marygold window, as it is called in England, or "La Roſe du Portail," as the French term it, was eaſily produced. In all the works executed during the middle and latter part of the twelfth century, a confuſed and heterogeneous mixture of ſtyles is every where diſcernible, as might be expected where circular faſhion began to be left off, and the pointed one to be uſed inſtead of it.

In a general way, the arches were altered before the columns. Hence nothing is ſo common as to find in the ſtructures erected between 1140 and 1180, arches of the ſharpeſt points, reſting on circular Saxon pillars of the greateſt circumference. It could not, however, long eſcape the obſervation of our indefatigable architects, that ſuch heavy ſupporters ill accorded with the lightneſs of the aſpiring arch. Accordingly, towards the latter end of this twelfth century, in ſome inſtances the circular Saxon column began to be ſhaped like the Arabic numerical figure 8, ſo as to retain its former ſtrength, and to appear gracefully ſlender; and where columns were made uſe of more for decoration than for ſtrength, as for example to ſupport ornamental arcades, or the cornices of windows or doors, very thin detached columns were employed, and thoſe for the moſt part made of Purbeck or Petworth marble. We have a ſtriking and moſt intereſting example of theſe and other improvements which took place in the pointed ſtyle, towards the latter part of the twelfth century, in the eaſt end of Canterbury cathedral. Perſons who cannot ſee the original, will find it accurately repreſented in Mr. Carter's treaſury of original ſpecimens, called "The Ancient Architecture of England." This portion of our Metropolitan church was rebuilt, after an accidental fire had deſtroyed the upper part, and weakened the remainder of it, between the years 1175 and 1180. As we have the incomparable advantage of poſſeſſing a circumſtantial account of this building, and of the differences between it and the former ſtructure, raiſed a hundred years before by archbiſhop Lanfranc, which account is drawn up by the intelligent monk Gervaſe of Canterbury, who was an eye-witneſs of what he relates, we ſhall ſubjoin ſome of the moſt material parts of it; he tells us then, that the pillars of the new choir were of the ſame form and thickneſs with thoſe of the old choir, but that they were twelve feet longer; that the former capitals were plain, while the latter were delicately carved; that there were no marble columns in Lanfranc's work, but that there was an incredible number of them in the work of the two Williams; that the ſtones which formed the ancient arches were cut with an axe, but thoſe of new arches with a chiſſel; that the vaulting of the ſide aiſles of the choir was plain, whilſt that of the new choir was groined and fixed with key-ſtones; that the former choir had a flat ceiling ornamentally pointed; but that the ſucceeding choir was elegantly vaulted with hard ſtone for its ribs, and light toph ſtone for the interſtices; finally, that there was only one *triſorium*, or gallery, round the ancient choir, whilſt there were two ſuch in the modern choir. The eaſt end of this venerable cathedral, as it is ſeen at the preſent day, and as it is repreſented by Mr. Carter, exactly correſponds in theſe and in other particulars with this deſcription of it, given 600 years ago. It is all in the firſt order of the pointed ſtyle, except the main pillars, which are (to the eye) round, with a ſort of Corinthian capital, and except the arches ſpringing from theſe pillars, which are alſo circular as far as the *concha abſidis* or altar end, theſe being pointed, as likewiſe with the exception of certain blockings and mouldings, where the Saxon billet ornament is ſtill ſeen.

The improved architecture of this, the moſt dignified church in the iſland, could not fail of being adopted in our other churches, when there was occaſion for rebuilding or repairing them. Lincoln cathedral ſeems to have led the way in this particular about the year 1195, under the direction of its biſhop St. Hugh, who was not leſs renowned for his ſkill in architecture than for the ſanctity of his life. This prelate undertook to rebuild the whole of his vaſt cathedral, and he was ſo intent upon the work, that, as Matthew Paris tells us, he carried mortar and ſtones on his own ſhoulders for the uſe of the maſons. The building was ſo far advanced at the time of his death, which happened in the year 1200, that he is conſidered and called its founder, though his work was not finiſhed till about fifty years afterwards, in the epiſcopacy of Robert Groſetete. Excepting the weſt front, which is almoſt all the work of the Norman prelate Remigius, and the towers, the groining, the ſkreens, and certain other decorations added in the fourteenth century, the whole vaſt pile of St. Mary's church and Chapter-houſe at Lincoln is in the ſimple ſtyle of the firſt or lancet order of pointed architecture; but awful and beauteous beyond the conception of thoſe who have not ſeen it, and greatly ſuperior to any church of the ſame order and period to be found in France. In 1202, the rich and powerful biſhop Godfrey de Lucy, amongſt his other great works, began to rebuild the eaſtern part of his cathedral at Wincheſter, which he executed in the ſtyle of the Metropolitical choir, but without the leaſt mixture of the Saxon. His extenſive work is ſtill to be ſeen there, conſiſting of long narrow ſharp-pointed windows and other arches, detached pillars of Purbec marble, quatre-foil mouldings, and light groining of ſimple interſecting ribs. And, whereas, it became very uſual, for the ſake of gracefulneſs and alſo of uſe, where they were uſed as windows, to place two of theſe narrow arches cloſe together under another pointed [illegible] greater width, in conſequence of which a vacant ſpace occurred between their heads; a trefoil, quatrefoil, or cinquefoil was frequently introduced, with the happieſt effect, to fill up this ſpace. In 1227 archbiſhop Walter Grey began to rebuild the northern Metropolitan church in the prevailing ſtyle, and he actually finiſhed the ſouth croſs aiſle as it is now ſeen. The ſame kind of work was going on at this time at Worceſter, Saliſbury, and other cathedral and abbey churches. The laſt-mentioned church, which is an entire new foundation, begun by biſhop De Poore in 1220, and finiſhed by biſhop Bridport in 1258, exhibits, in its front and other parts, the double lancet arch, [illegible] the intermediate quatrefoil roſe, and all the other characters deſcribed above. There being occaſion, however, to place three lancet arches together in the windows of the upper ſtory, the head of the middle one was gracefully raiſed above the other two, an improvement which was ſoon adopted in many other churches. A ſtill more ſtriking improvement which took place, if not at Saliſbury for the firſt time, at leaſt about the time of its completion, was the elevation of the cornice, pediment, or canopy which had hitherto adhered, or at leaſt had been very near to the architrave of the arch. This was now raiſed, like the two ſides of a triangle, to a conſiderable height above it. The jambs of the pediment were at firſt rather ſhort, not reaching, by any means, ſo low as the ſpringing of the arch, and generally reſting on ſome ſmall flower or other ſlight ornament. The point of the canopy always terminated in a trefoil or other graceful ornament, but was not, as yet, adorned with crockets or foliage down the jambs. Biſhop De Poore, being tranſlated to Durham, began to ornament the eaſt end of his preſent cathedral in the ſtyle which he had introduced into the one he had left. Whilſt the work at Saliſbury was drawing towards a concluſion, that at Weſtminſter abbey, was beginning, namely, in the year 1245. The north tranſept, and part of the adjoining nave of the church, remain in almoſt the ſame ſtate they were left in by their founder Henry III. The windows of the laſt-mentioned portion of the abbey, together with the correſponding aiſle, are larger and better proportioned than any which had hitherto been ſeen in this iſland. Here alſo we meet with the cinquefoil roſe between the heads of the two lights; while the exterior windows of the triforium or gallery conſiſt entirely of a triple cinquefoil under a pointed arch. Theſe two models for the upper part of church windows were long followed. On the other hand, the arches and windows of the tranſept, being placed in a regular order, and very near to each other, preſented an appearance of thoſe large mullioned windows which, in the ſucceeding period of this ſtyle, came into faſhion. In this part alſo of the abbey church, namely, the inſide of the tranſept, we begin to meet with good ſtatuary.

During the reign of Henry's ſon, Edward I., which began in 1272, the architecture of this country, through the ingenuity and induſtry of its artiſts, acquired a new character, and may be ſaid to have grown into a new order of the pointed ſtyle. The firſt and diſtinguiſhing feature of this was the general adoption of the well proportioned and well turned aſpiring arch. The arches which had hitherto been conſtructed, though ſometimes accidentally perfect, were, for the moſt part, too acute. But the arches built at the latter end of the thirteenth century generally approached to the perfect proportion. This proportion, according to the beſt judges, is when an equilateral triangle can be inſcribed within the crown and impoſts of the arch. The arches alſo were gracefully turned. Beſides all this, they were now invariably ornamented in their heads with cuſps, ſo as to form trefoils, cinquefoils, or ſeptfoils. In like manner the pediments or canopies over the arches were univerſally purfled, that is to ſay, adorned with the repreſentation of foliage called crockets, from the corbel on which they reſted up to the rich flower or other elaborate finial in which they terminated. Theſe corbels or brackets now corresponded in height with the ſpringing of the arch, and moſtly exhibited buſts of the founders or other benefactors of the eſtabliſhment. Pinnacles, which hitherto had been both very ſimple and very rare, were, in this improved order, placed at the ſides of almoſt every arch, and on the top of almoſt every buttreſs, being invariably purfled and ſurmounted with rich finials. A pinnacle of a proportionable ſize being placed on a tower, inſtead of a buttreſs, became a broach or ſpire. Accordingly the uſe of ſpires became almoſt general in the fourteenth century. We even read of a new built tower being pulled down, becauſe it was unequal to bear the weight of this grand ornament, when a new one was built, which, with its ſpire, was as high as the church was long. In the ſame ſpirit of ornamental grandeur, the buttreſſes, ſupporting the upper part of the nave, inſtead of being concealed in the roofs of the ſide aiſles, were brought into view with ſuitable decorations, and made to ſtretch over the tops of thoſe aiſles, in what are called flying buttreſſes. The window no longer conſiſted of an arch divided by a ſimple mullion, and ſurmounted with a ſingle or a triple roſe, but was henceforward, in all grand churches, portioned out by mullions into three, four, five, ſix, and ſometimes into nine different bays or days, as the ſeparate lights in a window were then called; and theſe again were frequently ſubdivided by one or more tranſoms running acroſs them. Their heads alſo were varied by tracery work into a variety of architectural deſigns, and ſometimes, as at the weſt end of York, into the form of a beautiful flower. The plain niches of the thirteenth century became, in the fourteenth, gorgeous tabernacles, in which as much architectural ſkill was often diſplayed as in the whole church to which they belonged. Theſe tabernacles, as well as various other parts of the ſacred edifice, were filled with ſtatues, which frequently ſhewed equal ſpirit in the deſign and art in the execution. Finally, the ribs ſupporting the groined ceiling were no longer ſimple interſecting arches; but they branched out into tracery work, ſtill richer and more elegant than that in the grand windows of this period; and wherever the ribs met, they were tied together by an architectural knot or boſs, which generally exhibited ſome inſtructive device. It muſt not be forgotten, that during the latter part of this period, the pediments which before had been ſtraight, began to humour the ſweep of the arch, by which means they became leſs high and more graceful.

We have inſtances of theſe improvements, or rather of this new order of the pointed ſtyle, in the three remaining architectural croſſes, erected by Edward I. thoſe of Northampton, Geddington, and Waltham, to the memory of his queen Eleanor, who died in 1290; likewiſe in the magnificent tomb of his brother Edmund Crouchback in Weſtminſter abbey, who departed this life in 1296. But the moſt complete ſpecimen of the whole detail of theſe improvements is York Minſter, the nave of which, as it ſtands, was built between the years 1290 and 1330, and the choir ſome thirty years after the latter period. If any ſimilar ſtructure in the ſame ſtyle, but upon a ſmaller ſcale, could, in its time, have vied with this in beauty and grandeur, it was St. Stephen's chapel, Weſtminſter, now the houſe of commons, which Edward III. began to erect in 1348. Of the inimitable beauties of the latter erection, only a few ſcattered veſtiges remain, to ſhew the architectural antiquary what it was in its glory. There are few, if any, of our cathedrals and remaining abbey churches which were not rebuilt or reſtored in ſome conſiderable part or other of them, according to this improved order. Before 1321, biſhop Langton had added the Lady chapel to his cathedral of Litchfield, had groined the nave and choir, and had erected the magnificent weſtern façade. About the ſame time the greater part of the nave of Weſtminſter abbey church was rebuilt. Between the years 1327 and 1340, Exeter cathedral was groined, and its heavy Norman arches and pillars were changed into light and graceful pointed arches and cluſter-columns, by its munificent prelate Grandiſon. During the pontificate of archbiſhop Courtney, which began in 1381, and that of his ſucceſſor Arundel, the nave of Canterbury cathedral was rebuilt. During the ſame period that eminent prelate and architect, William of Wykeham, was employed in performing the ſame difficult tranſmutation of the nave of Wincheſter cathedral, which had been performed in that of Exeter. The circular columns and arches were not taken down, as has been generally ſuppoſed, but the former were caſed and the latter reduced to a point. This may be aſcertained by an attentive examination of the work within the roofs of thoſe ſtructures; and without this trouble, by ſimply looking at the nave of Glouceſter, St. Albans, or Rumſey great church, where the operation here deſcribed will appear to have been performed, on two or three of the circular pillars and arches at the weſt end, and to have been left off with reſpect to the other pillars and arches. The taſte for theſe improvements deſcended even to country pariſh churches, few of which did not ſooner or later exchange their ancient windows, at leaſt, for thoſe of the pointed ſtyle.

But human arts, like the human body, when they have attained to the perfection of their ſtate, tend towards their decline. This was the caſe with that ſingular invention, pointed architecture. Its riſe, progreſs, and decline, occupy little more in the chronology of the world than four centuries. As its characteriſtical perfection conſiſted in the due elevation of the arch, ſo its decline commenced by an undue depreſſion of it. This new ſtyle, or third order of pointed architecture, took place in the latter part of the fifteenth century, and is to be ſeen in the royal chapels of St. George, Windſor, of King's college, Cambridge, and of Henry VII., Weſtminſter. It cannot be denied, that the builders of theſe ſplendid and juſtly admired ſtructures diſplayed more art and more profeſſional ſcience than even their predeceſſors had done; but then they diſplayed this at the expence of the ſtyle itſelf, which they cultivated, and of the awful and devout impreſſions which this ſtyle was invented to excite. The ſpectator was now amazed to ſee huge maſſes of ſtone, called pendent capitals, each one of more than a ton weight, hanging in the air, which, inſtead of ſupporting the vaſt groins they were fixed in, were ſupported by them; the conſequence of this, however, was to bring the flat arches of the ceiling ſtill nearer to the eye, ſo that their curvature was henceforward diſcernible at their ſpringing rather than at their point. Finally, ingenuity was at this period much more affected than awfulneſs: hence thoſe royal chapels, and ſeveral mortuary ones built in Wincheſter, Peterborough, and our other grand churches, during the time of the two laſt Henries, are ſeen covered over with tracery, and loaded in their groins and friezes with buſts, armorial bearings, and rebuſes, beyond all due proportion, ſo that, however elegant the deſign, and exquiſite the execution of them generally is, a judicious ſpectator, after admiring them, fails not to prefer to them the chaſte grandeur of York Minſter, or even the unadorned majeſty of Saliſbury cathedral. The church-windows of this period were ſo multiplied and enlarged, as to become what a late writer, Mr. Whittington, profeſſes to admire "all window," but which they certainly could not become without great detriment to the character of awfulneſs in the church itſelf. The ſame depreſſion of the pointed arch took place on the outſide as in the inſide of the buildings of this period. Inſtead of the tapering pinnacles and lofty ſpires which had hitherto adorned the towers of churches, theſe ſtructures were now generally covered with round cupolas, and the portals, inſtead of being ſurmounted with crocketed pediments and graceful pinnacles, were generally encloſed within ſquare architraves, the chief ornaments of which were ſeen in the ſpandrels. All this, however, is to be underſtood with ſome exceptions. For example, biſhop Oliver King erected his church at Bath, about the year 1500, in a very ſimple faſhion of pointed artitecture, and biſhop Fox repaired the preſbytery and chancel of Wincheſter cathedral with a chaſte and taſteful elegance.

But the downfal of pointed architecture in this kingdom became inevitable from various cauſes, chiefly, however, from the loſs of its characters of majeſty and awfulneſs, the neceſſary conſequence of the depreſſion of its ſublime and graceful arch. The deſtruction of it was complete at the beginning of the reign of Edward VI., from which period, till the introduction of the pure Grecian ſtyle in the reign of Charles I., a real Gothic, or at leaſt a truly barbaric ſtyle took place, conſiſting of a confuſed medley of all the known ſtyles and orders of ſtyles, intermixed with globes, triangles, pyramids, obeliſks, frets, and other whimſical and ugly devices, as may ſtill be ſeen in the ſepulchral and other monuments of the period in queſtion.

From what has been ſaid, it appears that the term *Gothic* architecture is an improper one, as applied to any ſpecies of architecture whatſoever; that the mode of building which prevailed amongſt our anceſtors before the conqueſt, called the Saxon ſtyle, conſiſting of round pillars with rude capitals and baſes, and of circular arches, was ſtrictly Roman, being copied, even to its minute ornaments, from coeval originals at Rome, and having been firſt taught and practiſed in this iſland by Roman maſters; that this ſtyle was ſucceeded, before the middle of the twelfth century, by a ſtyle of architecture perfectly new, the eſſential character of which is the pointed arch, from which, by a natural proceſs, the ſlender cluſter column, the aſpiring cornice or pediment, the crocketed pinnacle and lofty ſpire, with the other ornaments mentioned above, actually grew; that this ſtyle was not borrowed from Northern Goths, nor Eaſtern Saracens, nor Weſtern Moors, nor Southern Italians (for in this ſtyle the Italians themſelves were but novices, and not very apt ones), but that it was diſcovered in this climate, moſt probably by the Engliſh Normans, the greateſt people of the 12th age, and the fondeſt of eccleſiaſtical architecture that ever exiſted; that the ſtyle was improved by the joint efforts of the Normans, Engliſh, and French, at a time when our kings were maſters of the faireſt provinces of France, and brought to its perfection, chiefly by the ingenuity and induſtry of the Engliſh, during a period in which England was in proſperity by her conqueſts, and France in deſolation from her defeats; that there are three diſtinct orders in this ſtyle, the members and proportions of which can be diſtinctly pointed out by profeſſional men, (ſuch as the author of the "Ancient Architecture of England") with almoſt as much accuracy as thoſe of the five Grecian orders; on which ſubject it may be obſerved, that theſe Grecian orders were practiſed long before their members and proportions were accurately laid down, that the characteriſtic of the firſt order is the acute arch, and that the period of its duration may, in a general way, be ſaid to have laſted from the middle of the twelfth to the end of the thirteenth century: of this order, Lincoln, Beverley, and Saliſbury churches are examples; that the chief characteriſtic of the ſecond order, is the perfect or equilateral arch, the reign of which was from the end of the thirteenth, till after the middle of the fifteenth century, to which order York Minſter, and the naves of Wincheſter and Canterbury cathedrals belong; and that finally, the characteriſtic of the third order is the obtuſe arch, which grew into faſhion about the laſt-mentioned period, and laſted to the downfal of pointed architecture itſelf in the middle of the ſixteenth century. The fineſt ſpecimens of this, doubtleſs, are the above-mentioned royal chapels. With reſpect to the proper denomination of this ſtyle, ſome of the learned, as well as the vulgar in general, ſtill call it the Gothic, others the Saracenic, a third claſs, the Norman, a fourth, the Engliſh, and a fifth, the pointed. From the whole of what has been ſaid above, it will be readily concluded, that the preſent writer conceives the laſt of theſe terms to be the beſt adapted to the ſtyle, as being the moſt ſtrictly deſcriptive of its characteriſtical quality.

This article is the abridgment of a much longer treatiſe on pointed architecture, which is ſhortly expected to appear from the preſs of Mr. Taylor's Architectural Library; in which treatiſe many hiſtorical documents in ſupport of the preſent ſyſtem, and certain plates to illuſtrate it, will be ſeen. M.

Gothic *Bible*. See Bible, and Argenteus *Codex*.

Gothic *Character*, or *Writing*, is a character or manner of writing, which, in the main, is the ſame with the Roman, only that it is very full of angles, turns, and bendings, eſpecially at the beginning and ending of each letter.

The manuſcripts in Gothic characters are not very ancient. Ulphilas, biſhop of the Goths, was the firſt inventor of the Gothic characters, or the firſt who compoſed the Gothic alphabet, in imitation of the Greek, and the firſt that tranſlated the bible into the Gothic tongue.

The letters uſed in the Gothic goſpels are twenty-five in number, and formed, with ſlight variations, from the capitals of the Greek and Latin alphabet.

As theſe characters, in which the *Codex* Argenteus, or Gothic verſion of the bible, was written by Ulphilas, their inventor, were derived partly from the Greek and partly from the Latin, Michaelis (Introd. to the N. T.) thinks it natural to aſcribe the ſaid verſion not to the Franks or Germans, but to the Goths, who lived on the borders of the Danube; or in Wallachia, where they at that time reſided, the Latin was ſpoken, and their neareſt neighbours were the Greeks. A mixed alphabet, ſuch as that which is found in the Codex Argenteus, is ſuch as might reaſonably be expected. Some of the words in this verſion are ſtill uſed in the Leſſer Tartary, the ancient ſeat of the Goths; *e. g. ſwiltan*, "to die," from *ſwalt*, "death," a word that is quoted by Buſbeck, from the language of the Crim Tartars. In this verſion, many words are adopted immediately from the Greek; *viz.* αττα, *atta*, father; *ams*, ωμος, the ſhoulder, where even the *s* is retained from the Greek termination, &c. Hence it is inferred, that the dialect, in which ſuch words occur, was that of a nation that lived in the neighbourhood of the Greeks. This verſion has alſo Sclavonian words, ſuch as *ſan*, a maſter, which prove it to have been written in the dialect of a nation that bordered on Sarmatia. The ſame may be ſaid of many Latin words: ſuch as *anacumbjan*, accumbere, to ſit at table, *militondans*, militantes, ſoldiers, *agha*, water, &c. This argument is the more deciſive, when we conſider, that the Goths, in the time of Ulphilas (ſee his biographical article,) lived in Wallachia, a country in which Roman colonies had been planted, and where a corrupt Latin is ſpoken at this very day. Ulphilas himſelf lived in Wallachia, and had it in his power at leaſt to make uſe of Latin letters, as well as thoſe of the Greeks, with whom he had continual intercourſe. See Gothic *Language*.

The Runic characters are alſo frequently called Gothic characters. See Mabillon, De Re Diplomat. lib. i. cap. 2.

But they who take the Gothic characters to be the ſame with the Runic, are miſtaken ; as is ſhewn by Ol. Wormius, Junius in his preface to the Goſpels written in Gothic letters, and Dr. Hicks on the Runic Tongue.

Gothic *Column* is any round pillar in a Gothic building, either too thick or too ſmall for its height.

There are ſome found even twenty diameters high, without either diminution or ſwelling.

Gothic *Language*, the language of the Goths. This language, as the acknowledged parent of the Engliſh, is of conſiderable importance ; while its remote antiquity, the ſcantineſs of its records, and the circumſtance of its having been ſtudied only by few among the learned, have rendered it a matter of great uncertainty as to its character and origin. The queſtions reſpecting its antiquity and genius are reſolvable into thoſe in regard to the people who uſed it. Monſ. Mallet, in his "Northern Antiquities," ſuppoſes that the ancient Gauls and Germans, the Britons and the Saxons, were all originally one and the ſame people : and thus he makes the Gothic the ſame with the Celtic tongue. This opinion, which was firſt taken up by Cluverius in his "German Antiquities," has been ſince adopted by Keyſler in his "Northern and Celtic Antiquities," and Pelloutier in his "Hiſtory of the Celts," and maintained by them with uncommon erudition. According to theſe writers, the ancient and original inhabitants of Europe conſiſted only of two diſtinct races of men, *viz.* the Celts and Sarmatians ; and from one or other of theſe, but chiefly from the former, all the ancient nations of Europe are deſcended. The Sarmatians, or Sauromatæ, were the anceſtors of all the Sclavonian tribes, *viz.* the Poles, Ruſſians, Bohemians, Wallachians, &c. who continue to this day a diſtinct and ſeparate people, extremely different in their character, manners, laws, and language from the other race, which was that of the Celts ; from whom, as they ſuppoſe, were deſcended the old inhabitants of Gaul, Germany, Scandinavia, Britain, and Spain, who were all included by the ancients under the general name of Hyperboreans, Scythians, and Celts, being all originally of one race and nation, and having all the ſame common language, religion, laws, cuſtoms, and manners.

This opinion, though ſupported with an uncommon diſplay of deep erudition and a great variety of ſpecious arguments, is controverted by the late learned and ingenious Dr. Percy, in a preface to Monſ. Mallet's Northern Antiquities, which he has tranſlated and enriched with notes. This profound antiquarian, in oppoſition to the French writers, ſtates that ancient Germany, Scandinavia, Gaul, and Britain, were not inhabited by the deſcendants of one ſingle race ; but, on the contrary, divided between two very different people ; the one of whom he calls with moſt of the Roman authors Celtic, who were the anceſtors of the Gauls, Britons, and Iriſh ; the other Gothic or Teutonic, from whom the Germans, Belgians, Saxons, and Scandinavians derived their origin ; and that theſe were *ab origine* two diſtinct people, very unlike in their manners, cuſtoms, religion, and laws.

The Gothic, then, is radically different from the Celtic according to Dr. Percy, who, on the authority of Hicks, as ſtated in the preface to his "Inſtitutiones Grammaticæ Angloſaxonicæ," gives the following genealogy of the two languages. Gothic is the parent of 1. Old Saxon, or Anglo-Saxon ; 2. Francic or Franco-Theotiſc ; 3. Cimbric, or Old Icelandic. From the firſt, *viz.* the Anglo-Saxon, are again derived Engliſh, Broad Scotch, Belgic, or Low Dutch, and Friſic. From the Francic, are derived German, or High Dutch, German of Swabia, and Swiſs ; while the Cimbric, in its turn, gave birth to the Icelandic, Norwegian or Norſe, Daniſh, and Swediſh. On the other hand, the Celtic is repreſented by the ſame writer as the parent of the ancient Gauliſh, the ancient Britiſh, (ramified into the Corniſh, Armorican, or Bas-Bretagne, and Welſh,) and the ancient Iriſh, which was ſubdivided into Manks, or language of the Iſle of Man, into Erſe, or Highland Scotch, and Iriſh. To the old original mother tongue of all the Gothic dialects, it has been uſual to give the name of Teutonic, not ſo much as Dr. Percy aſſerts from its being the language of Tuiſto, the great father and deity of the German tribes, as from the Teutones, the people who uſed it : the ſame probably with the Cimbri, or as the Greeks called them *Κιμμεριοι*, who inhabited the northern regions, and more particularly the Daniſh iſlands. Now, in oppoſition to this writer, we are free to affirm, there is no ground for believing that this mother tongue, whether called Gothic or Teutonic, was in its primæval form different from the Celtic. And this propoſition we ſhall endeavour to make manifeſt from the very ſpecimens by which Dr. Percy has attempted to ſhew their eſſential difference. But before we enter on this queſtion, it is neceſſary to remark, that learned men, in their enquiries concerning the origin of nations, have not ſufficiently attended to the conſideration which we learn from the Moſaic hiſtory, that all nations originated in a common family, and at firſt ſpoke a common language. Let us ſuppoſe that ſome members or deſcendants of this family, (as we read of Gomer,) emigrated from Aſia to Europe. If they ſettled in Greece, they introduced with them the primæval cuſtoms, and language, though ſomewhat corrupted no doubt from its original purity. Others, actuated by the ſame ſpirit of emigration, would ſoon follow ; and, if more powerful, would diſlodge their predeceſſors, who had no other reſource but to ſeek new habitations in remoter regions.

As theſe wanderers multiplied, they advanced, till, in the courſe of years, all the countries on the north and weſt, as well as on the eaſt of Europe, were completely peopled. But this population of courſe could not take place before they had been divided into independent tribes, and diſtinguiſhed by correſpondent difference in dialects and manners. But ſtill a very great reſemblance muſt have as yet been viſible among them in both theſe reſpects, however ſeparated from each other : for in the earlier periods of ſociety, language, though widely uſed, muſt long have continued the ſame, with little variations, it being corrupted and diverſified into diſtinct tongues only by the progreſs of civilization, by the refinements of literature, by improvements in art and in government, and by thoſe political convulſions which the love of conqueſt, inſpired by conſcious ſuperiority in thoſe arts, produces. All the nations of Europe, therefore, in the ruder and more early ages, may be conſidered as uſing only the ſame great primordial ſpeech, grown indeed into diſtinct branches, and aſſuming in one country the appearance of being independent of, and unconnected with thoſe uſed in other countries. Now, if we ſuppoſe that the Celtæ were the firſt emigrants from Aſia, who, pervading Europe, ſettled in Gaul, Old Spain, Britain and Ireland ; while their brethren, under the names of Getæ (Goths), Scythæ, Cimbri, &c. directing their courſe to the North, occupied Thrace, Scandinavia, and other northern territories ; it would follow, that theſe tribes, however remote, uſed at firſt either the ſame language, or languages which had a cloſe affinity from their relation to the common primæval tongue. Nor would there be material difference in this concluſion, though we ſhould ſuppoſe, with many learned men, that the inhabitants of the North of Europe came, not from the Eaſt but from the

the North of Aſia, as they muſt ſtill have been deſcendants of the ſame primitive family, which, according to Moſes, peopled the world. Thus the Celtic and the Gothic or Teutonic muſt have been, in their origin, the ſame or ſiſter tongues.

But further, while the ancient Celts and Goths continued in the darkneſs for which they became proverbial, the inhabitants of Greece rapidly improved in laws and the arts of life. In this improved ſtate, Greece became, in regard to the leſs favoured inhabitants of the North and Weſt, what Aſia had hitherto been in reſpect to Greece, a freſh ſource of civilization and letters. Its language, growing more copious and refined with the people, diffuſed itſelf with the bleſſings of knowledge and ſociety, which their example or inſtruction imparted to the Northern and Weſtern inhabitants of Europe. Thus Greek, with the arts of Greece imported into Italy, gave birth to the Latin tongue; and this at a later period neceſſarily affected the Celtic language, in conſequence of the victories which the Roman arms atchieved in Gaul and in Britain. This revolution greatly widened the line of diſtinction which for ages had been extending between the Celtic and the Gothic tongues; the former being aſſimilated to the Latin, the latter to the Greek, by a copious influx of new terms. It were indeed matter of great curioſity if ſome records of the Celtic and Gothic tongues had been preſerved before they were yet modified by the aſcendant languages of Greece and Rome; but no ſuch records unfortunately have ſurvived the wrecks of time. And we can judge of the ancient Celtic only from the Welſh, its acknowledged daughter; while we are left to form our judgment of the primæval Gothic from the remnants of a verſion of the New Teſtament, effected by Ulphilas, into the dialect uſed by the Goths in Mœſia, and hence called Mœſo-Gothic.

Having made this preface to ſhew that the Celtic and Gothic had one common baſis, *viz.* the primordial tongue imported from Aſia, we proceed to prove, as far as we are able from their reſpective offspring, that they had in common many Aſiatic words, and were modified by a great portion of Latin and Greek terms: and that from theſe two cauſes they eſſentially reſembled each other. The Lord's prayer is thus rendered in the ancient Gothic of Ulphilas.

	Literal tranſlation :
1 Atta unſar thu in himinam	1 Father our thou in heaven
2 Veihnai namo thein	2 Be ſanctified thy name
3 Quimai thiudinaſſus theins	3 Come thy kingdom
4 Vairthai Vilga theins ſue in himina, gah ana airthai	4 Be done thy will ſo in heaven, alſo on earth
5 Hlaif unſerana thana ſeintinan gif uns himmidaga	5 Give us this day the bread eternal
6 Gah aflet uns thatei ſculans ſigaima, ſua ſue gah veis afletam tham ſculam unſeram	6 And forgive us that we are debtors, as alſo we forgive thoſe our debtors
7 Gah ni bringais uns in fraiſtubngai	7 And bring us not into temptation
8 Ak lauſei uns afthamma ubilin, Amen.	8 But deliver us from evil, Amen.

The following is a ſpecimen of the Celtic, as exiſting in the Welſh tongue:

1 Ein Taad, yr hwn wyt yn y Nefoeth	1 Our father, the one who art in heaven
2 Santeiddier dy enw	2 Be hallowed thy name
3 Deved dy deyrnas	3 Come thy kingdom
4 Bydded dy Ewyllys ar y ddaiar megis y mae yn y nevoeth	4 Be thy will on the earth as it is in the heaven
5 Dyro i ni heddyw ein bara beynyddiol	5 Give to us this day our daily bread
6 A madde i ni ein Dyledion fel y maddeuwn ni ein dyledwyr	6 And remit to us our debts as that we remit to our debtors
7 Ag nac arwain ni i brofedigaeth	7 And lead us not into trial
8 Eithr gwared ni rhag drwg, Amen.	8 But deliver us from evil, Amen.

We propoſe next to lay before our readers a brief analyſis of theſe two ſpecimens, which it is preſumed will ſhew that the two languages in queſtion have much nearer reſemblance to each other, than Dr. Percy, or any perſon who has not a thorough knowledge of both, could poſſibly imagine. The Hebrew דד, *dd*, pronounced with an initial and cloſing vowel, is *adda*, and ſignifies *beloved*, and this is the ſource of the Gothic *atta*, and the Greek αττα, with the utmoſt propriety applied to a parent as the deareſt object of love. The ſame word in Hebrew is written דוד, *dood*, and is no other than the Celtic *taad*, under a difference of character. In the Corniſh it is *taz*, in the Friſic *haita*, in the Lapland *atki*, and the old Cantabrian or Biſcayan *aita*, *father*. *Unſar* is the Greek ἡμετερος, thus ſtrangely corrupted, ἡμετες, *untar*, *unſar*; and hence the Engliſh *our*. In the ſame manner, ὑμεις has degenerated into *ums*, *uns*, *us*. The Celtic *ni* is the Hebrew and Arabic pronoun אני, *ani*, which, ſounded with only the cloſing vowel, is *ni*, *us*, and with only the initial *ein*, *our*. The Gothic *in* and the Welſh *yn* have originated in the Greek εν, or the Latin *in*; but it is obſervable that both theſe languages uſe this prepoſition as it is uſed in Latin, when followed by an accuſative noun in the ſenſe of *into*, *unto*, or *to*: thus *in fraiſtubngai*, into temptation; *inni*, or *i ni*, *to us*. The Welſh language is remarkable for the attention paid to harmony in the arrangement of its terms. To produce this effect the termination of a preceding word, in order to coaleſce with the ſucceeding one, is ſomewhat changed, and thus made to unite both into one. Thus *rhwn* is *yr hwn*, *the one*, where *r* or *rh* (aſpirated after the manner of the Greek ῥ) is prefixed to *wn*, the Latin *unus*, or the Anglo-Saxon *an*. *Wyt*, moreover, is a coalition of *wy ty*, *art thou*, or *thou art*; *wy* being the ſubſtantive Greek verb εω or ειμι, whence the Goths derived their *im*, and the Engliſh our *am*. The Greek χειμων, *tempeſt* or *clouds*, by ſoftening the guttural into an aſpirate, of which we ſhall preſently give ſome more examples, has in the Gothic degenerated into *himin*, the place where the tempeſts or clouds reſide, namely, the *ſky* or *heaven*. In the Franco-Theotiſc the ſame word is *himil*, and in the Cimbric *himal*. It exiſts alſo in the Celtic; but there it has retained its original ſound and ſenſe, under the form of *cwmwl*, *a cloud*. It is ſingular that the ſame aſſociation of ideas, founded on the nature of things, has transferred the Greek νεφος, or the Latin *nubes*, to ſignify in Welſh *heaven*, under the ſhape of *neof* or *nefoedd*.

2. *Veihnai* is the verb of *veiha* or *veihs*, *holy*, which is but the Greek ἁγιος, with the labial *v* ſubſtituted for the aſpirate, as the old Latins have done in numerous inſtances, ſome of which we ſhall preſently produce. On the other hand, *ſantiddier* is *ſanctus*, converted by the Welſh into a verb; while

dy is the ſame with the Gothic *thu*, and no other than the Latin *tu*, or the Æolic τυ, or the Engliſh *thou.* The Gothic *thein*, it is obvious, has given birth to the Engliſh form of *thine.* *Namo*, whence our *name*, retains the Perſian character of *naam*, though perhaps it is more immediately derived from *nomen*, and is a kindred noun with the Welch *enw*, which probably degenerated from ονομα, by dropping the laſt ſyllable.

3. The Arabic קואים, *quaem*, *legs*, has given birth to the Gothic *quiman*, *to uſe the legs*, *i. e.* to come, and to the Anglo-Saxon *cyman*, and our *come.* The ſame word has been imported into the Celtic in the ſhape of *cammu*, ſignifying to *hop* or *ſtep*. The ſame word exiſts in the Shanſcrit, *gumun*, *to go.* The correſponding Welſh *deved* or *dywad*, is the Greek ταω, ταζω, or τεινω, *to ſtretch to an object*, which laſt deſcended from the Arabic אתי, *ata*, by dropping the initial vowel. The ſame verb exiſts in Welſh, under the different figure of *thowy* or *thowys*, and is no other than the Engliſh *tow*, *to conduct.* The Gothic *thiudinaſſus*, *a kingdom*, ſeems originally to have meant *the emperor of a ſubdued nation*, from the Greek θητευς and αναξ, or ανασσω, as the offspring of the former exiſts in this tongue *thiuda*, *gens*, *populus.* On the other hand, the Welſh *deyrnas* is the Greek θρονος, corrupted, by the tranſpoſition of *r*, into *thornos* or *dyrnas*. Our Engliſh *throne* conforms to the original in ſound and ſenſe. In the Anglo-Saxon the correſponding word is *ryc*, which ſtill exiſts in ſuch Engliſh compoſitions, as *biſhopric*, *i. e.* the dominion of a biſhop. In the Great Indian language abovementioned, this term ſubſiſts under the character of *reyh*, meaning *wealth*, and which is nearly the ſame in ſound and ſenſe with the Anglo-Saxon *ryc*, or our *rich*, and the Latin *res*, *property*.

4. As *light* or *air* is the chief medium of exiſtence, the Hebrew term אור, *awar*, gave birth to the Latin *eram*, *ero*, and the Gothic *wair* or *wairthan*, *to be*, *to become.* The Welſh *bydded*, which exiſts alſo in the form of *byw*, and which is the ſame with the Greek βιοω, and the Latin *vivo*, deſcended from the Perſian *bodan*, *to be.* *Wilga* is βουλω, or *volo*, with *ga* annexed, by an analogy common in the Gothic tongue. The Welch *wollys*, or with *e* prefixed, *ewyllys*, has flowed from the ſame ſource; and under the former of theſe forms is nearly allied to the Engliſh *will.* *Sue* is our *ſo*, or the Greek ὡς reverſed, a fate very common with monoſyllables in the ancient languages. *Gah* came from και, and *ana* from ανα, which, in compoſition, means *up*, and has given birth to the Gothic ſenſe of *upon.* *Airthai* is the Arabic *ardd*, from the Hebrew ארץ, *arets;* while the Welſh *daiar*, or as it is otherwiſe written, *tyr*, originated in *terra.* The Hebrew עבר, *aber*, the parent of ὑπερ in Greek, of *uber* in German, *ufer* in Gothic, and *over* in Engliſh, has contracted in Celtic into *ar*, in the ſenſe of *upon.*

5. The Arabic עלף, *âleph*, *food*, is the origin of the Gothic *hlaif*, and the Engliſh *loaf.* *Thana*, or *than*, is the accuſative article τον. *Sintinein* is formed from the noun *ſinth*, *viciſſitude*, *change*, which is no other than the Hebrew שנה or שנת, *ſinth*, that change or period of time called a year: hence *ſintinein* came to ſignify *continual*, or *perpetual.* Our Lord, we believe, by the clauſe τον αρτον τον επιουσιον, meant not, as it is generally rendered, *daily bread;* but the bread belonging to us, and eſſential to us as immortal beings, namely, the bread of the ſoul. (See " Mr. Jones's Illuſtrations of the four Goſpels," p. 123.) In this ſenſe the clauſe was underſtood by the early commentators, and by the Gothic tranſlator, who has rendered it *hlaif thana ſintinein*, the eternal bread. In Hebrew, Arabic, and Perſian, כף, *kaph*, denotes the palm of the hand; hence it came to ſignify the action of the hand, which conſiſts either in imparting or receiving. In the former ſenſe it gave birth to the Gothic *gif*, and in the latter to the Latin *capio.* *Himmidaga* means *this day;* *himma*, or as we write it, *him*, being the perſonal pronoun uſed definitively, and *diga*, or *daeg*, according to the Anglo-Saxon, being the Latin *dies;* *him day* for *this day*, which is more common in the plural form among the vulgar *them days.*

The Welch *dyro*, in the ſame verſe, is the Greek δωρον, *a gift*, converted into a verb. *Heddyw* is a diſguiſed form of *hodie*, which laſt is only a contraction of *hoc die*, this day. *Bara* is a word which exiſts in all languages. Its origin is the Hebrew פרה, *pharah*, *fruit:* and hence πυρος in Greek, *far*, and *pario* in Latin, *brodh* in Cimbric, *brot* in Francic, *broodt* in German, *branta* in Norſe, *bread* in Engliſh, *brod* in Daniſh, and *brae* in Friſic. *Brynhyddiol*, rendered *daily*, appears to be compoſed of *bryn*, *a top* or *ſummit*, and *yddiol*, the Latin *dies* adjectived, and means a top of each day, or a head of each day, *i. e.* daily. The word is alſo uſed *beynyddial*, *beyn* being a corruption of *pen*, a head. The Welſh are fond of this expreſſion, and have a phraſe, *poeb dyth ar y pen*, each day on his head, meaning every day in ſucceſſion.

6. *Aflet uns*, i. e. *of-let*, or *let off*, *diſmiſs to us.* *Thatei* is a corruption of the Greek τουτο, *this* or *that thing*, and is thus the parent of the Engliſh *that:* hence the reaſonableneſs of the explanation which the celebrated Mr. Tooke has given of ſuch phraſes—remit to us *that thing*, *viz.* *ſculans ſigaima*, we are debtors. *Sculans* were perſons under command, under obligation or debt, from the Greek σκυλλειν, *to labour:* hence appears to have been derived our *ſcullion*, a mean domeſtic ſervant. In ancient times labourers uſually paid their rents in kind from the products of their fields: hence, in Greek, the tenant was called χειρωφειλετης. On the ſame principle, in Gothic, the word ſignifying *to labour*, came to ſignify *to owe*, or *to be in debt.* *Sigaima* is only the Latin *ſimus* corrupted by the inſertion of *ga*, a particle of frequent uſe in Gothic. The Welſh *a mathe*, or as it may be written, *ammaddeu*, is a compoſite of *ag madde*, *and remit*, the firſt being the Latin conjunction *ac*, the ſecond the Greek μεθιεω, the ſame with μεθιημι, *to diſmiſs* or *remit.* *Dyledion*, the plural of *dyled*, is the Latin *deleta*, things to be *eraſed*, or to be cancelled by being paid, *i. e.* debts. The noun *wr*, or the plural *wyr*, which in this tongue is ſo often added to the name of a thing, is but the Latin *vir*—*dyledwyr*, *debtmen* or *debtors.*

7. The Goths and Anglo-Saxons corrupted φερειν into *beoran* and *bringan*, and hence our *to bear*, and *to bring*—*ni bringai*, do not bring us. The Latin *nē* in Gothic is *ni*, in Anglo-Saxon and Engliſh *no*, in Welſh *na* or *nag.* *Fraiſtubngai* is the correſponding noun of *fraiſan*, to tempt, and appears to have been borrowed from the Latin *preſſus*, and therefore primarily meant *preſſure*, *ſtraightneſs.* The Welſh *arwain* is the French *rene* with the vowel *a* prefixed, and is the ſame with our *rein:* its proper ſenſe is to lead a horſe with a bridle. The French, in deriving words from the Latin, generally reject the guttural in the middle or at the end; and on this principle the root of *rene* is *regno*, *to rule*, *direct.* *Profedigaeth* ſtrictly denotes *experience*, and its origin is the Latin *probo*, which laſt is itſelf taken from the Greek φορβη, *paſture*, or the correſponding verb φερβω, *to taſte* or *chew.*

8. The Gothic *ak* is the Latin *ac*, though uſed by the latter in a conjunctive, by the former in a disjunctive ſenſe—*but.* The root is αεξω, or the thence derived *augeo*, whence the Gothic *augan:* and *ak*, conformably to the form of this

laſt verb, is alſo written *auk* in the ſenſe of *nam*, *enim*. The correſponding Welſh word is *eithr*, derived from ἑτερος, *another*. The explanation of it is this—lead us not into trial; another thing, *i. e.* do another thing, namely, deliver us from evil: on this principle the conjunction αλλα, *but*, originated in αλλος. *Lauſei*, which has given birth to various words in Anglo-Saxon and in Engliſh, and among the number to *looſe*, *loſe*, *leaſe*, *releaſe*, *let*, is apparently the offspring of the Hebrew לוז, *luz*, *decedo*, *recedo:* to *deliver* from evil is but to cauſe to recede from evil, and thus *lauſen* correſponds in ſenſe as well as in ſound to the original. A looſe character is a character freed or looſened from the rules of ſobriety and juſtice, and this deviation from rectitude is implied in the original לוז; while the compound *releaſe* comes cloſe to the Gothic ſignification of *lauſan*, to deliver. The Welſh which anſwers to this is *gwared*, and is no other than the Latin *gero*, (properly pronounced *guero,) to manage*, *to carry*. The Arabic פרע, *pharâ*, is the origin of our word *free*, its primary ſenſe. Being thence applied to men, it came to ſignify thoſe who were the *heads* of families, or who went before them: hence it was uſed to convey the more general and abſtract ideas of precedence or *beginning*; in this ſenſe it is the origin of πρωι in Greek, *præ* in Latin, *fra* or *fram* in Gothic, *ifra* in Cimbric. In the Anglo-Saxon *m* is annexed, and hence our word *from*, though the Scotch uſe it in the original purity of *frae*. The correſponding Welſh *rhag*, which means *far*, *diſtance*, has retained with great exactneſs the ſound and ſenſe of רחק, *rhak*, its Hebrew original. The Gothic *ubil*, German *ubel*, Anglo-Saxon *iſle*, and Engliſh *evil*, is the Perſian and Arabic בלי, *bala*, with a vowel prefixed. The Perſian *tarīk*, is the parent of the Engliſh *dark:* and as darkneſs was the ſymbol of *evil*, or of the ſuppoſed dæmon which created it, the Celts received it to expreſs *evil* under the form of *drwg:* and it is remarkable that the ſame word with *alpha privativum* is uſed by the Greeks to denote a contrary ſenſe—ατρεκης, *not dark*, *ingenuous*, *ſincere*, *true*. In the ſame language τρωκτης means an *impoſtor*, which the lexicographers, miſled by mere ſimilarity of ſound, have erroneouſly referred to τρωγω, *to eat*.

From this analyſis, which we hope is worthy the attention of the learned, we ſhall draw a few concluſions reſpecting the Gothic tongue. Firſt, it appears to reſemble the Celtic, in having a common Aſiatic baſis, and in containing a copious influx of Greek and Latin words. As the two languages were not eſſentially different, there is no foundation for ſuppoſing, with Dr. Percy, that the Celts and the Goths were originally diſtinct races of men. And here we cannot help ſpecifying a feature in theſe tongues, which, in a remarkable manner, beſpeaks their original identity, or their immediate deſcent from a common parent.

The Gothic, with its offspring the Anglo-Saxon and the German, uſes the particle *ga* or *ge* prefixed to words, and eſpecially to verbs. The Gothic ſometimes inſerts *g* in the middle of words, and frequently before the infinitive termination of verbs: αυξειν, or *augere*, is *wahſgan*, and χλευειν, *to deride*, *hlahgan*, *to laugh*. In conſequence of this analogy, words borrowed from Greek and Latin are remarkably diſguiſed, and they muſt be ſtripped of this peculiarity before they can be traced to their true origin. The Celtic, if we may judge from the Welſh, was diſtinguiſhed by the ſame characteriſtic feature: thus, the Latin *vir* is *gwr; vinum*, *gwyn; vagus*, *gwaeg*, &c. On this principle ὁμως, *like*, *as*, in Welch is *megis*, which bears the ſenſe of the original. The identity or ſimilitude of the two languages will account for the Goths and Celts being called by the common name of Cimmerians or Cimbri, which the true Britons, the undoubted deſcendants of the Celts, ſtill inherit under the name of Cymri.

Sir W. Jones, in his ſixth diſcourſe delivered to the ſociety at Calcutta on the antiquities of Aſia, has the following paſſage well worthy of our attention, as tending to confirm, in a remarkable manner, the reſult of the preceding inquiry. The paſſage is this: "It has been proved by clear evidence and plain reaſoning, that a powerful monarchy was eſtabliſhed in Iran long before the Aſſyrian government; that it was in truth a Hindoo monarchy, though, if any chuſe to call it Cuſean, Caſdean, or Scythian, we ſhall not enter into a debate on mere names; that it ſubſiſted many centuries, and that its hiſtory has been ingrafted on that of the Hindoos, who founded the monarchies of Ayodhya and Indraprеſtha; that the language of the firſt Perſian empire was the mother of the Sanſcrit, and, conſequently, of the Zend and Parſi, as well as of Greek, Latin, and Gothic; that the language of the Aſſyrians was the parent of Chaldaic and Pahlavi, and that the primary Tartarian language alſo had been current in the ſame empire; although, as the Tartars had no books, or even letters, we cannot, with certainty, trace their unpoliſhed and variable idioms. We diſcover, therefore, in Perſia, at the earlieſt dawn of hiſtory, the three diſtinct races of men, whom we deſcribed on former occaſions as poſſeſſors of India, Arabia, and Tartary; and whether they were collected in Iran from diſtant regions, or diverged from it, as from a common centre, we ſhall eaſily determine from the following conſiderations. Let us obſerve, in the firſt place, the central poſition of Iran, which is bounded by Arabia, by Tartary, and by India; whilſt Arabia lies contiguous to Iran only, but is remote from Tartary, and divided even from the ſkirts of India by a conſiderable gulf. No country, therefore, but Perſia ſeems likely to have ſent forth its colonies to all the kingdoms of Aſia: the Brahmans could never have migrated from India to Iran, becauſe they are expreſsly forbidden by their oldeſt exiſting laws to leave the region, which they inhabit at this day; the Arabs have not even a tradition of an emigration into Perſia before Mohammed; nor had they, indeed, any inducement to quit their beautiful and extenſive domains: and as to the Tartars, we have no trace in hiſtory of their departure from their plains and foreſts till the invaſion of the Medes, who, according to etymologiſts, were the ſons of Madai, and even they were conducted by princes of an Aſſyrian family. The three races, therefore, whom we have already mentioned, (and more than three we have not yet found,) migrated from Iran, as from their common country: and thus the Saxon Chronicle, I preſume on good authority, brings the firſt inhabitants of Britain from Armenia; while a late very learned writer concludes, after all his laborious reſearches, that the Goths or Scythians came from Perſia; and another contends, with great force, that both the Iriſh and Old Britons proceeded ſeverally from the borders of the Caſpian; a coincidence of concluſions from different media, by perſons wholly unconnected, which could ſcarce have happened, if they were not grounded on ſolid principles. We may, therefore, hold this propoſition firmly eſtabliſhed, that Iran or Perſia, in its largeſt ſenſe, was the centre of population, of knowledge, of languages, and of arts; which, inſtead of travelling weſtward only, as it has been fancifully ſuppoſed, or eaſtward, as with equal reaſon might have been aſſerted, expanded in all directions to all the regions of the world." Here we ſee it ſtated, as the reſult of ſir William Jones's inquiry, that the Goths, the Iriſh, and the Old Britons, or the Celtæ, were originally the ſame people, and of Aſiatic origin; that they uſed the ſame language derived from the primæval language of Aſia: and this he gives not merely as the conſequence of his own inveſtigation, but as a coincidence of concluſions, through different media, by perſons wholly unconnected." We know not whether this great man was aware of the great ſimilitude ſubſiſting between the Gothic and the Celtic tongues. From his ſilence we may conclude that he was not: and if he had ſeen ſpecimens of them, analyſed ſimilar to that above, he would have deemed the reſemblance a ſurpriſing confirmation of his theory.

We conclude, in the ſecond place, from the above analyſis, that the Gothic had a cloſe affinity to the Greek and Latin. And ſir William Jones gives it as his opinion, that the Greek, Latin, and Gothic originated in one and the ſame language; namely, the ancient language of Perſia. Theſe three languages, therefore, originally reſembled each other, not merely becauſe they borrowed ſome words one from the other, but becauſe they had the ſame words, phraſes, and even conſtruction, in conſequence of having derived them from a common tongue. And here we cannot help mentioning one feature in which the ancient Gothic bore a very ſingular reſemblance to the Greek in the time of Homer, or that dialect of the Greek (namely, the Æolic), from which the Latin was principally derived: we mean the much diſputed Æolic *digamma.* In the Oriental languages gutturals abounded: theſe, by degrees, ſoftened into a mere aſpirate; and for this aſpirate was, in very numerous inſtances, ſubſtituted a *labial* letter *w* or *v*, or *f*, or ϝ. Thus *khaan, a king*, degenerated into *hân;* and being introduced into Greek in the form of αναξ, or ανασσω, was pronounced ϝαναξ, ϝανασσω. While the oral Greek was thus corrupted, the written retained the aſpirate; and as the works of Homer became the ſubject of univerſal ſtudy, the true orthography triumphed over the caprice of oral ſounds. But the Latins had no ſuch monument of genius as the Iliad to ſtudy: the corruptions of pronunciation, therefore, prevailed, and the digamma was univerſally ſubſtituted for the aſpirate. Thus ἑστια, *veſta*, ἑσπερα, *veſpera.* The digamma was alſo prefixed to a broader open vowel, and always inſerted between a diphthong, as οις, pronounced *owis, ovis;* οινος, *woinos, vinum;* οικος, *woikos, vicus.* Now, this ſame digamma runs through the Gothic language, which ſhews that a great part of it, through ſome channel or other, was derived from the Greek, about the early age in which the Latin ſeparated into a diſtinct dialect. We ſhall give a few examples of this fact. The Greek αναξ, in Gothic, is written conformably to the corrupt pronounciation of ϝαναξ, *fân;* αειν, *ſpirare*, is *waian;* αεξειν, (which is equivalent to αυξανειν) is *wahſgan, creſcere;* εργαζειν, *waurkgan;* hence the Engliſh, *to work.*

But though the Greek may have the ſame form and baſis with the Gothic; and though by ſome communications, now unknown, it may have enriched the Gothic with its own early improvements, yet the dialect dignified with this name is only the remains of the Gothic tongue, debaſed by a ſtrong mixture of Greek and Latin terms, a century or two after the commencement of the Chriſtian era. The Goths who uſed it lived in Wallachia, a country in which Roman colonies had been planted, and which was contiguous to the provinces of Greece. As the verſion of Ulphilas, contained in the "Codex Argenteus," is the only repoſitory of this dialect, it is worth while to hear what Michaelis ſays of it in his "Remarks on the Ancient Verſions," Marſh's tranſlation, vol. ii. p. 142. "In the "Codex Argenteus," many words are adopted immediately from the Greek. Here I underſtand, not ſuch as have been common to the German and the Greek from the earlieſt ages of antiquity, and ſhew either an original relation, or original connection between the two nations, but ſuch Greek words as are found in no other German dialect than that of the "Codex Argenteus," and have been transferred from the Greek, after the complete formation of both languages: for inſtance, αττα, *father, ams, the ſhoulder*, ωμος, where even the *s* is retained from the Greek termination. *Spyreïdans, baſkets*, σπυριδες; *rhatizo, eaſier*, ῥαδιος; *maizo, greater*, μειζων; *aſtaſſais*, (αποστασιου,) *bokos, bill of divorce.* This betrays not a dialect that was uſed in Germany, or in the North, but that of a nation that lived in the neighbourhood of the Greeks. Even the mode of expreſſing the ſound of *ng*, in the "Codex Argenteus," is purely Greek, and never uſed in Germany, where the Latin orthography has been received; for *finger* is written in that manuſcript *figgr*, as the Greeks would have expreſſed it by a double gamma." Ulphilas is ſaid to have invented the characters of this dialect; which are evidently a mixture of the Greek and Latin alphabet. The uſe of ſuch characters was natural, if the dialect which they expreſſed contained a great mixture of the languages to which they properly belonged.

This repreſentation muſt greatly diminiſh our veneration for the Gothic, as far as it can be known by us; yet, in this light, it demands our attention and reſpect as the undoubted parent of the Engliſh tongue. Nevertheleſs, we are hence compelled to regard the Gothic and the Anglo-Saxon as but corrupt channels by which the terms of Greece and Rome have been imported into our own language. There are, indeed, thoſe who conſider them in this humble and degraded ſtate, as claiming the dignity of original, ancient, and independent languages. And Mr. Horne Tooke, in particular, in his celebrated work on grammar, has attempted to induce the public to receive corruptions from Greek and Latin in the dark ages, as the original words of a Northern language; whence Greek and Latin have, according to him, themſelves been derived. The merits of this queſtion will more properly be diſcuſſed under the articles GRAMMAR and GREEK. But if the account we have given of the Gothic be juſt, we ſhall want no other evidence to convince us that the theory of Mr. Tooke, as far as this queſtion is concerned, (and it forms a very leading feature of his ſyſtem,) is not only erroneous, but ridiculous and abſurd.

GOTHIC *Medals.* See MEDAL.

GOTHIC *Muſic.* When ſig. Eximeno calls fugues and canons Gothic compoſitions, he does not diſgrace their ſtructure any more than he would our cathedrals, by calling them Gothic buildings. Let fugues be baniſhed from the theatre and private concerts, if he pleaſes, but let them remain in the church as a diſtinct ſpecies of compoſition, where they were firſt generated, and where they can never become vulgar or obſolete. The ſtyle is naturally grave, requires muſical learning, and will, by the ſolemnity of the words and place of performance, continue to be reverenced and reſpected. It is allowed that variety is more wanted in muſic than in any other art, and by totally excommunicating canons and fugues from the church, the art would loſe one capital ſource of variety, as well as ingenuity; and intelligent hearers be bereaved of a ſolemn ſtyle of muſic, to be heard no where elſe.

GOTHINI, or GOTHUNI, in *Ancient Geography*, a name given to the Goths. They were called Getones by Tacitus and Juſtin, and Guttones by Pliny. Claudian calls them Gothuni.

GOTHLAND, a country of Sweden, bounded on the N. by Sweden Proper, on the E. and S. by the Baltic, and on the W. by the Sound, the German ocean, and Norway. This country is inhabited by a people, who derived their origin from the Getæ, or Tartars of the Crimea. The Goths had kings of their own, till the year 1132, when they were united to Sweden. The country is pleaſant and fertile, conſiſting of paſture and arable land; and abounding in lakes and rivers plentifully ſtored with fiſh, and alſo with foreſts and mines. It contains 48 towns, and is divided into Eaſt, Weſt, and South Gothland.

Eaſt Gothland is bounded on the N. by the provinces of Nericia or Nerike, and Sudermanland, on the E. by the Baltic, on the S. by Smoland or Smaland, and on the W. by the Wetter lake, which ſeparates it from Weſt Gothland. It is about 80 miles long, and 70 broad. It produces wheat, rye, barley, oats, peaſe, &c. in ſuch abundance as to ſupply the neighbouring provinces. It has likewiſe many fine orchards, with meadows, paſtures, lakes, and rivers abounding with fiſh, extenſive foreſts, iron-mines and founderies, and quarries of ſtone and marble. The inhabitants are occupied in huſbandry, hunting, and fiſhing, and alſo in ſome places in the mines. The chief towns of this province are Nordkioping, Soderkioping, Linkioping, and Wadſtena; which ſee reſpectively.

South Gothland is divided into three provinces, *viz.* Schonen or Skone, Halland, and Blekingen, which have at ſundry times changed their maſters, till at length Charles Guſtavus annexed them for perpetuity to the Swediſh dominions, by the treaty of Roſchild, in the year 1658.

Weſt Gothland is bounded on the N. by Warmeland, on the E. by Nericia, the Wetter lake, and Smaland, on the S. by Smaland and Halland, and on the W. by the Scaggerac. It is about 115 miles long, and 15 broad; like Eaſt Gothland it was under the adminiſtration of its own kings and laws. The ſoil produces corn, vegetables, and fruit; and affords excellent paſtures, which enable the occupiers to ſupply other provinces with butter and cheeſe. The rivers, lakes, and ſea-coaſt abound with fiſh; and in ſeveral places are erected iron-forges, alum-works, paper mills. The inhabitants are chiefly employed in agriculture and fiſhing. The chief towns are Gotheborg, Wenneſborg, Lidkioping, and Falkioping; which ſee reſpectively.

GOTHLAND, or *Gottland*, an iſland belonging to Sweden, ſituated in the Baltic, between N. lat. 56° 54′, and 57° 56′, and E. long. 18° 6′, and 19° 6′; about 70 miles long and 25 in its greateſt breadth. It was formerly an independent kingdom, but is now ſubject to the ſupreme court of juſtice at Stockholm. Its ſituation has gained for it the appropriate denomination of the "Eye of the Baltic." The ſoil is fertile, and affords fine woods of oak and pine, and good paſtures; and its breed of ſheep is accounted excellent. It has large quarries of ſtone, which is exported to Stockholm and other places, and ſome curious ſpecies of ſtone corals, carnelians, agates, and beautiful petrifactions. It furniſhes likewiſe good lime-ſtones, tar, and deal-boards. Although it is not infeſted with bears or wolves, it abounds with foxes, deer, and hares. The inhabitants gain their ſubſiſtence by tilling the ground, grazing, fiſhing, working in the quarries, burning lime, and other ſorts of mechanic trades, and navigation. The peaſants are in a ſtate of abſolute dependence on the burghers, who ſupply them with neceſſaries, and with money for paying their taxes, and to whom they ſurrender the whole produce of their induſtry, without ſtipulating any price. This iſland was at firſt ſubject to the crown of Sweden, and afterwards to the Danes for near two centuries, till the year 1645, when by the treaty of Bromſebro, it was reſtored to Sweden. The capital of the iſland is Wiſby, on the weſtern coaſt.

GOTHS, a people, who came originally, according to Jornandes (Rer. Get.) who abridges the Gothic hiſtory of the learned Caſſiodorus, compriſed in 12 books, from the vaſt iſland, or rather peninſula, called Scandinavia, and including the preſent Sweden, Norway, Lapland, and Finmark. The learned Grotius, and after him Sheringham, and moſt of the northern writers, maintain by arguments, which, as many conceive, have not been refuted, but which are not convincing to others, that the Cimbrians (ſee CIMBRI), Getes (ſee GETÆ), and Goths, were the ſame nation; that Scandinavia was firſt peopled by them; and that from thence they detached colonies into the iſlands in the Baltic, the Cherſoneſus, and the adjacent places, yet deſtitute of inhabitants. Many veſtiges, which cannot be aſcribed to the arts of popular vanity, atteſt the ancient reſidence of the Goths in the countries beyond the Baltic. From the time of the geographer Ptolemy, the ſouthern part of Sweden ſeems to have continued in the poſſeſſion of the leſs enterpriſing remnant of the nation, and a large territory is even at preſent divided into Eaſt and Weſt Gothland. (See GOTHLAND.) The time when the Goths firſt ſettled in Scandinavia, and the period at which they firſt peopled with their colonies the iſlands, the Cherſoneſus, and the neighbouring places, have not been aſcertained. Some have ſaid, that their firſt ſettlement was conducted by Eric, contemporary with Sarach, grandfather of Abraham. However this be, the peopling of the iſlands in the Baltic ſea, of the Cherſoneſus, and of the adjacent places on the continent, is called by the Northern writers, the *firſt* emigration of the Goths or Getes. The attempt to croſs the Baltic was natural and eaſy. The inhabitants of Sweden (as we learn from Tacitus) were maſters of a ſufficient number of large veſſels with oars; and the diſtance is little more than 100 miles from Carlſcroon to the neareſt ports of Pomerania and Pruſſia. At leaſt as early as the Chriſtian era, and as late as the age of the Antonines, the Goths were eſtabliſhed towards the mouth of the Viſtula, and in that fertile province, where the commercial cities of Thorn, Elbing, Koningſberg, and Dantzick were long afterwards founded. Weſtward of the Goths, the numerous tribes of the Vandals were ſpread along the banks of the Oder, and the ſea-coaſt of Pomerania and Mecklenburg. A ſtriking reſemblance of manners, complexion, religion, and language, ſeemed to indicate that the Vandals and Goths were originally one great people. (See VANDALS.) In the age of the Antonines the Goths were ſtill ſeated in Pruſſia. About the reign of Alexander Severus, they made frequent and deſtructive inroads into the Roman province of Dacia. In this interval, therefore, of about ſeventy years, we muſt place the *ſecond* emigration of the Goths, from the Baltic to the Euxine. To what cauſe this was owing is matter of mere conjecture. Perhaps a peſtilence or a famine, a victory or a defeat, an oracle of the gods, or the eloquence of a daring leader, were ſufficient to impel the Gothic arms on the milder climates of the ſouth. Beſides the influence of a martial religion, the number and ſpirit of the Goths were equal to the moſt hazardous adventures. The uſe of round bucklers and ſhort ſwords rendered them formidable in a cloſe engagement; the manly obedience which they yielded to hereditary kings gave uncommon union and ſtability to their councils; and the renowned Amala, the hero of that age, and the tenth anceſtor of Theodoric, king of Italy, enforced, by the aſcendant of perſonal merit, the prerogative of his birth, which he derived from the *anſes*, or demigods of the Gothic nation.

Whatever was the motive of their migration, they took their route eaſtward, entered Scythia, advanced to the Cimmerian Boſphorus, and, driving out the Cimmerians, ſettled in the neighbourhood of the Mæotic lake. Thence, in proceſs of time, they ſent out numerous colonies into Thrace, Dacia, Mœſia, or Italy, and laſtly into the countries bordering on the Euxine ſea, forcing every where the ancient inhabitants to abandon their native abodes. Such is the account given by Jornandes, and Ablavius, a celebrated writer among the Goths, who lived long before him. In the vicinity of the Mæotic lake, they had, it is ſaid, Filimir for their king, who was a warlike prince; in Thrace, Mœſia, and Dacia, Xamolxis, a great philoſopher; and in the countries on the Euxine ſea, princes of the illuſtrious families of the Balthi and the Amali, the Viſigoths being ſubject to the former, and the Oſtrogoths to the latter. In all theſe countries they were the ſame people, though ſubject to different princes, and known by various appellations. As for the denominations of Weſtrogoths, ſoftened by the Latins into that of Viſigoths, and Oſtrogoths, they were diſtinguiſhed by thoſe names before they left Scandinavia, being called Weſtrogoths and Oſtrogoths, or weſtern and eaſtern Goths, from their ſituation to the weſt and eaſt, the former inhabiting that part of Scandinavia which borders on Denmark, and the latter the more eaſtern parts, near the Baltic. The information we derive from Jornandes concerning the various migrations and ſettlements of the Goths is conformable to the accounts that are given by the ancient Greek and Latin authors with reſpect to the different colonies and ſettlements of the Getes. That the Goths and Getes were the ſame people, is ſuppoſed by all the writers who flouriſhed in or near the times in which both empires were overrun by them. Thoſe authors, without doubt well acquainted with their origin, call them ſometimes Goths, ſometimes Getes, and ſometimes Scythians; and ſeveral authors tell us, that the Getes and Goths had been long known to the Romans, and alſo to the Greeks by the former names, but not by the latter, till their incurſions into the empire.

When the Goths greatly increaſed in Scythia, they reſolved to ſeek new ſettlements; and accordingly, purſuing their route eaſtward, and travelling through ſeveral countries, they returned at length into Germany. Their leader in this migration was the celebrated Woden or Odin, of whom many ſtrange things are related. It is ſaid by the northern writers, that he was king of the Aſgardians, ſuppoſed to be the ſame people with the Aſpurgians mentioned by Ptolemy and Strabo. Aſgardia and Aſpurgia are ſaid to be a common name of their city, ſituated, according to Strabo, near Boſphorus Cimmerius; and Aſpurgia was the metropolis of a country which Strabo calls Aſia; hence Woden and his followers are ſtyled by the ancient Gothic writers Aſæ, Aſiani, and Aſiatæ. The kings of Aſpurgia are repreſented as being maſters of all that part of Scythia that lay weſt of mount Imaus, and which the Latins called "Scythia intra Imaum," or Scythia within mount Imaus. Of this Aſgardia or Aſpurgia, Woden is ſaid to have been king; and hence he emigrated with a great multitude of his followers in queſt of new ſettlements; or, as ſome ſay, with the great deſign of forming in Sweden, conſidered as the inacceſſible retreat of freedom, a religion and a people, which, in ſome remote age, might be ſubſervient to his purpoſes; when his invincible Goths, armed with martial fanaticiſm, ſhould iſſue in numerous ſwarms from the vicinity of the Polar circle to chaſtiſe the oppreſſors of mankind. Having paſſed through different countries, and performed a variety of exploits, he at length arrived in Sweden, where he was allowed to ſettle, and where he reigned till his death. His name became ſo famous that the northern nations ranked him among the gods, and worſhipped him with divine honours. He is ſuppoſed to have brought with him out of Aſia the Runic characters (ſee Runic), and to have taught the northern nations the art of poetry; whence he is ſtyled the father of the Scaldi or Scaldri. See Scalds.

That the Goths, under the conduct of Woden, came from Scythia into the northern parts of Germany, is a received opinion among the northern writers, and, as they allege, confirmed by an immemorial tradition, by the ancient chronicles of thoſe countries, and by many monuments and inſcriptions in Runic characters, ſome of which are ſtill to be ſeen in Sweden, Denmark, and the neighbouring iſlands. That there were ſuch migrations can hardly be queſtioned, ſince we find the ſame names common to the inhabitants of Scandia and Aſiatic Scythia, and likewiſe the ſame language, as Grotius, and after him Sheringham, have ſhewn. The ancient language of the Goths is now ſpoken by the Tartars of Precop, whence, and from other collateral circumſtances, it has been concluded that the Scandian Goths and Aſiatic Scythians had one and the ſame original. As to the time of this migration of Scythians under Woden into the northern parts of Germany, thoſe who maintain it have not been able to determine. Some refer it to a period about 24 years B. C.; for at that time, they ſay, Pompey laid waſte Syria, and great part of Aſia, and menaced the north with ſervitude. After all, this wonderful expedition of Woden or Odin is admitted with great heſitation, or indeed ſcarcely admitted at all by many, into authentic hiſtory. According to the obvious ſenſe of the Edda (ſee Edda), and the interpretation of the moſt ſkilful critics, Aſ-gard, inſtead of denoting a real city of the Aſiatic Sarmatia, is the fictitious appellation of the myſtic abode of the gods, the Olympus of Scandinavia; from whence the prophet was ſuppoſed to deſcend, when he announced his new religion to the Gothic nations, who were already ſeated in the ſouthern parts of Sweden.

Before we proceed with our brief abſtract of the hiſtory of the Goths, we ſhall give ſome account of their character, cuſtoms, laws, and religion, before they embraced Chriſtianity. With regard to their general diſpoſition and character, they were celebrated for their hoſpitality and kindneſs to ſtrangers; and it is ſaid that they derived their name from their being eminently good; the name of Goth being derived, according to Grotius and other writers, from the German word *goten*, ſignifying *good*. They encouraged, ſays Dio, the ſtudy of philoſophy more than any other barbarous or foreign nation, and often ſelected their kings from among their philoſophers. Polygamy was not only allowed, but encouraged, and every one was reſpected according to the number of his wives, and of courſe his children. Adultery with them was a capital crime, and invariably puniſhed with death. This ſeverity, and likewiſe polygamy, prevailed among them, when they were known to the Greeks and Romans only by the name of Getes, as appears from the poet Menander, who was himſelf a Gete, and from Horace (l. iii. od. 24.) who beſtows great encomiums on the virtue and chaſtity of their women. Of their laws we ſhall have occaſion to ſpeak in the ſequel of this article. Their government was monarchical. Their religion ſeems to have been the ſame with that of the ancient inhabitants of Scandinavia and Saxony; which ſee reſpectively. Till the end of the eleventh century, a celebrated temple ſubſiſted at Upſal, the moſt conſiderable town of the Swedes and Goths. This temple was enriched with the gold which the Scandinavians had acquired in their piratical adventures, and ſanctified by the uncouth repreſentations of the three principal deities, the god of war, the goddeſs of generation, and the god of thunder. In the general feſtival that was ſolemnized every ninth year, nine animals of every ſpecies (without excepting the human) were ſacrificed, and their bleeding bodies ſuſpended in the ſacred grove adjacent to the temple. The only traces that now ſubſiſt of this barbaric ſuperſtition are contained in the *Edda;* which ſee. See alſo Odin.

Caracalla was the firſt Roman emperor who quarrelled with the Goths, and marched againſt them into that part of Dacia, north of the Danube, of which they had taken poſſeſſion; but the advantages which he ſeems to have gained over them in a few ſkirmiſhes were very inconſiderable. It appears, that the Romans were alarmed at an early period by the progreſs of this warlike nation; for in the reign of Alexander, which began in 222, conſiderable ſums of money were ſent to them from Rome, in order to prevent their diſturbing the peace of the empire. Notwithſtanding theſe bribes, as ſoon as they heard of the aſſaſſination of the emperor Maximin, who was of Gothic extraction, they reſolved to revenge it, and accordingly entering Mœſia, they totally laid waſte that province. Not long after they made themſelves maſters of Thrace, from which they were driven by Gordian. Under Philip, his ſucceſſor, they committed dreadful ravages both in Thrace and Mœſia. Soon after their retreat from the ſiege of Marcianopolis, the capital of the ſecond Mœſia, and after having compelled the inhabitants to ranſom their lives and property, they paſſed the Danube a ſecond time, under the command of their king, Cniva, with a more conſiderable force; and having obliged Darius the ſon of the Roman emperor, to ſave himſelf by flight, they were oppoſed by the emperor himſelf. Darius, having compelled them to raiſe the ſiege of Nicopolis, they retired towards Philoppolis, took it by ſtorm, and maſſacred, as is ſaid, 100,000 perſons in the ſack of that city. The time, however, which was conſumed in this tedious ſiege, enabled Darius to revive the courage, reſtore the diſcipline, and recruit the number of his troops, after the defeat they had ſuſtained in their purſuit of the Goths. Thus recruited, the emperor exerted his utmoſt vigilance to oppoſe either the progreſs or the retreat of the barbarians. The Goths were now, on every ſide, ſurrounded and purſued by the Roman arms; and exhauſted by the long ſiege of Philoppolis, they would gladly have purchaſed, by the ſurrender of all their booty and priſoners, the permiſſion of an undiſturbed retreat. The emperor, confident of victory, refuſed to liſten to any terms of accommodation; and the high-ſpirited barbarians preferred death to ſlavery. The two armies, therefore, prepared for an engagement. The conflict was ſevere; two lines of the Gothic army were thrown into diſorder; and the third only remained entire, prepared to diſpute the paſſage of a moraſs, which was imprudently attempted by the Roman troops. Here the fortune of the day aſſumed a new aſpect. In this moraſs the Roman army, borne down by the weight of their armour, after an ineffectual ſtruggle, was irrecoverably loſt; nor could the body of the emperor ever be found. Upon the election of Gallus A. D. 251, the firſt object of his attention was to deliver the Illyrian provinces from the intolerable weight of the victorious Goths. He offered them every inducement in his power to withdraw their forces; and he even promiſed to pay them annually a large ſum of gold, on condition they ſhould never afterwards infeſt the Roman territories by their incurſions. This tribute, however, though granted at the expence of the honour of the Romans, was inſufficient to ſecure their permanent repoſe. New ſwarms of barbarians, encouraged by the ſucceſs, and conceiving themſelves not bound by the obligation of their brethren, ſpread devaſtation through the Illyrian provinces, and terror as far as the gates of Rome. In this period of alarm and diſtreſs, Æmilianus, governor of Pannonia and Mœſia, rallied the ſcattered forces of the empire; and the barbarians were unexpectedly attacked, routed, chaſed, and purſued beyond the Danube. Under the reigns of Valerian and Gallienus, the frontier of the laſt-mentioned river was perpetually infeſted by the inroads of the Germans and Sarmatians; but it was defended by the Romans with more than uſual firmneſs and ſucceſs. Nevertheleſs, the great ſtream of the Gothic hoſtilities was diverted into a very different channel. The Goths, in their new ſettlement of the Ukraine, ſoon became maſters of the northern coaſt of the Euxine: to the ſouth of that inland ſea were ſituated the wealthy provinces of Aſia Minor, which poſſeſſed all that could attract, and nothing that could reſiſt, a barbarian conqueror. The little kingdom of Boſphorus, whoſe capital was ſituated on the ſtraits, through which the Mæotis communicates itſelf to the Euxine, was compoſed of degenerate Greeks, and half-civilized barbarians. In this ſmall kingdom, domeſtic factions, and the fears, or intereſt, of obſcure uſurpers, who ſeized on the vacant throne, admitted the Goths into the heart of Boſphorus.

Here they acquired a naval force ſufficient to tranſport their troops to the coaſt of Aſia. For this purpoſe, they conſtructed a ſort of flat-bottomed boats, called "Camaræ," framed of timber only, without any iron, and occaſionally covered with a ſhelving roof, on the appearance of a tempeſt. With this kind of fleet, they firſt appeared before Pityus, at the utmoſt limit of the Roman provinces, with a convenient port, and fortified with a ſtrong wall. Their firſt attack was repulſed; but, renewing their attempts, they deſtroyed this city. Then circling round the eaſtern extremity of the Euxine ſea, their navigation from Pityus to Trebiſond was a courſe of about 300 miles. This city was large and populous, defended by a double incloſure of walls, and had its uſual garriſon ſtrengthened by a reinforcement of 10,000 men. But this numerous garriſon was diſſolved in riot and luxury, and thus rendered careleſs in guarding their impregnable fortifications. The Goths, availing themſelves of the ſupine negligence of the beſieged, erected a lofty pile of faſcines, aſcended the walls in the ſilence of the night, entered the defenceleſs city, ſword in hand, maſſacred the inhabitants, deſtroyed the temples and ſplendid edifices, and gained an immenſe booty. With the rich ſpoils of the city they filled a great fleet of ſhips, which they found in the port, and, ſatisfied with the ſucceſs of their firſt naval expedition, returned in triumph to their new eſtabliſhments in the kingdom of the Boſphorus. In their ſecond naval expedition, poſſeſſed of greater powers both of men and ſhips, they took a new courſe, followed the weſtern coaſt of the Euxine, paſſed before the wide mouths of the Boryſthenes, the Nieſter, and the Danube; and increaſing their fleet by a great number of fiſhing barks, they approached the narrow outlet through which the Euxine ſea pours its waters into the Mediterranean. In this expedition they plundered the cities of Bithynia, Chalcedon, Nice, Pruſa, Apamea, Cius, and Nicomedia. From the recent attack of Pruſa, the Goths advanced within 18 miles of Cyzicus; but their progreſs was ſtopped by the ſmall river Rhyndacus, which iſſues from the lake Apollionates, and which was then ſwelled into a broad and rapid ſtream. Their retreat to the maritime city of Heraclea, where their fleet was probably ſtationed, was attended by a long train of waggons, laden with the ſpoils of Bithynia, and was marked by the flames of Nice and Nicomedia, which they wantonly burnt. The third naval expedition of the Goths conſiſted of 500 ſail of tranſports, containing about 15,000 warriors. They now ſteered their deſtructive courſe from the Cimmerian to the Thracian Boſphorus; and were carried to the lake of the Propontis. Their landing on the little iſland of Cyzicus was followed by the ruin of that ancient and noble city. They thence iſſued through the narrow paſſage of the Helleſpont, and purſued their winding navigation amidſt the numerous iſlands ſcattered over the Archipelago, or Ægean ſea. At length the Gothic fleet anchored in the port of Piræus, five miles from Athens, ravaged Greece, and cauſed the rage of war, both by land and ſea, to ſpread from the eaſtern point of Sunium, to the weſtern coaſt of Epirus, advancing within ſight of Italy. The indolent Gallienus was rouſed; the emperor appeared in arms; and his preſence contributed to check the ardour of the enemy. Some of the numerous Gothic hoſt broke into Mœſia, for the purpoſe of forcing their way over the Danube to their ſettlements in the Ukraine. Others returned on board their veſſels, and re-tracing their courſe through the Helleſpont and the Boſphorus, and finding themſelves ſecure within the baſon of the Euxine, landed at Anchialus, in Thrace, near the foot of mount Hæmus, and refreſhed themſelves by the uſe of thoſe pleaſant and ſalutary hot-baths. Amidſt their devaſtations, we may ſelect the deſtruction of the famous temple of Diana at Epheſus, which they burnt in their third naval invaſion. It is alſo ſaid, that they threatened to deſtroy all the libraries of Athens, but were prevented from executing their menace by the profound obſervation of one of their chiefs, that as long as the Greeks were addicted to the ſtudy of books, they would never apply themſelves to the exerciſe of arms. Under the reign of Claudius, A. D. 269, the Goths collected an armament more formidable than any that had yet iſſued from the Euxine. On the banks of the Nieſter they conſtructed a fleet of 2000, or even of 6000 veſſels, which, in their paſſage through the Boſphorus, encountered various diſaſters. However, they made ſeveral deſcents on the coaſts, both of Europe and Aſia. But diſcontent and diviſion aroſe in the fleet, and ſome of their chiefs deſerted them, and ſailed away towards Crete and Cyprus: the main body, nevertheleſs, purſued their courſe, anchored at the foot of mount Athos, and aſſaulted the city of Theſſalonica. Their attacks were ſoon interrupted by the rapid approach of Claudius. The Goths, eager for a general engagement, relinquiſhed the ſiege of Theſſalonica; and with this view, leaving their navy at the foot of mount Athos, traverſed the hills of Macedonia. Claudius was diſtreſſed, but at the ſame time firm and determined. The event exceeded even his own expectations, as well as thoſe of the world; and having gained ſignal victories, and delivered the empire from this hoſt of barbarians, he was diſtinguiſhed by poſterity under the glorious appellation of the Gothic Claudius. The deciſive battle was fought near Naiſſus, a city of Dardania. The war was afterwards diffuſed over the provinces of Mœſia, Thrace, and Macedonia, and the ſuperior talents of the emperor generally enſured the ſucceſs of his arms. The Goths ſuffered to ſuch a degree, that a ſelect body of their youth was received among the Imperial troops, the remainder was ſold into ſervitude, and the female captives were ſo numerous, that every ſoldier appropriated to himſelf two or three women. To complete the diſaſters of the Goths, their fleet was either taken or ſunk, ſo that their retreat was thus intercepted. Aurelian, the ſucceſſor of Claudius, diſtinguiſhed himſelf during the Gothic war, and, at laſt, put an end to it by a laſting and beneficial treaty. The Gothic nation engaged to ſupply the armies of Rome with a body of 2000 auxiliaries, conſiſting entirely of cavalry, and, in return, ſtipulated an undiſturbed retreat, with a regular market as far as the Danube, provided by the emperor's care, but at their own expence. But the moſt important condition of peace was underſtood rather than expreſſed in the treaty. Aurelian withdrew the Roman forces from Dacia, and tacitly relinquiſhed that great province to the Goths and Vandals. This proved, in the event, a wiſe meaſure; for, after Dacia became an independent ſtate, it ſeemed as the firmeſt barrier of the empire againſt the invaſions of the ſavages of the North.

About the year 277, the ſecond of the reign of Probus, the Goths entered Thrace, and advanced as far as Illyricum, laying waſte the country with fire and ſword; but as ſoon as they heard that the emperor was marching againſt them, they retreated and left their booty behind them. In Illyricum, Probus was met by deputies from the Gothic nations, ſuing for peace, and ſubmitting to his power. No further mention is made of the Goths till the year 289, at which time Diocleſian is ſaid to have gained a complete victory over them. From this victory Diocleſian aſſumed the name of "Sarmaticus," as appears from ſeveral ancient coins and inſcriptions. From this year to the 15th of Conſtantine, the Goths gave no diſturbance to the empire, being engaged in wars with the neighbouring nations. As ſoon as the Goths were diſengaged from other wars, they invaded the Roman empire; but they were overcome by Conſtantine in ſeveral battles, fought at Campana, in Pannonia, and at Margus and Bononia, in Upper Mœſia. The emperor determined to chaſtiſe as well as to repulſe the inſolent barbarians who had dared to attack the territories of Rome, paſſed the Danube, and penetrated into the inmoſt receſſes of Dacia; and when he had inflicted a ſevere revenge, condeſcended to give peace to the ſuppliant Goths, on condition that as often as they were required, they ſhould ſupply his army with a body of 40,000 ſoldiers. In the year 331, a war broke out between the Goths and Sarmatians; on which occaſion the latter had recourſe to Conſtantine, who was glad to embrace an opportunity of humbling that ferocious nation. In the firſt action the barbarians gained the advantage; but the event of a ſecond and more ſucceſsful action, in April 332, retrieved the honour of the Roman name. Near 100,000 of the enemy were either put to the ſword, or periſhed after the battle with hunger and cold; and this defeat was ſo ſignal, as to oblige Alaric, king of the Goths, to ſue for peace, and to deliver hoſtages to the emperor, one of whom was his own ſon. The Goths not only continued quiet, but ſerved the Romans with great fidelity, during the remaining part of Conſtantine's reign; and in the reigns of Conſtans, Julian, Trajan, and Valentinian I. But in the firſt of Valens, they made inroads into Thrace, and laid waſte that province. The emperor purchaſed their retreat for a ſum of money. In the following year news was brought him to Bithynia, that the Goths were again ready to break into Thrace. When Procopius revolted, and aſſumed the title of emperor, the Goths eſpouſed his cauſe, and ſent a body of troops to his aſſiſtance; but before their arrival, he was defeated and put to death. They, however, continued in the territories of the empire, committing great ravages in Thrace and Mœſia. Valens ſent a ſtrong detachment againſt them, and their retreat being cut off, they were obliged to lay down their arms, and yield themſelves priſoners. After hoſtilities which laſted three years from 366 to 369, the barbarians ſubmitted, and thus appeaſed the reſentment of Valens. After the ratification of the treaty, Valens returned in triumph to Conſtantinople,

ſtantinople, and the Goths remained in a ſtate of tranquillity about ſix years; till they were violently impelled againſt the Roman empire by an innumerable hoſt of Scythians, who appeared to iſſue from the frozen regions of the North. In the year 375 the Huns invaded the territories of the Goths, and ſpread among them ſuch a general conſternation, that they fled for refuge to the Roman dominions. Valens liſtened to their ſupplications, and granted them protection. The liberality of the emperor, however, was accompanied with too harſh and rigorous conditions. Before they paſſed the Danube, they were required to deliver their arms; and it was inſiſted that their children ſhould be taken from them, and diſperſed through the provinces of Aſia; where they might be civilized by the arts of education, and ſerve as hoſtages to ſecure the fidelity of their parents. A probable teſtimony has fixed the number of the Gothic warriors at 200,000 men; and if we can venture to add the juſt proportion of women, of children, and of ſlaves, the whole maſs of people which compoſed this formidable emigration muſt have amounted to near a million of perſons, of both ſexes and of all ages. The Goths, juſtly provoked at the cruel treatment they met with from the Roman officers, who were to ſupply them with proviſions, had ſcarcely entered Thrace, under the conditions impoſed upon them, when they began to mutiny and plunder the country. This occaſioned a long and bloody war between them and the Romans. They were joined by the Huns, Alani, Taifalæ, and other ſwarms of their countrymen. In the battle of Hadrianople, A. D. 378, the Roman cavalry fled; and the infantry was abandoned, ſurrounded, and cut in pieces; and though the Goths were obliged to raiſe the ſiege of Hadrianople, the tide of the Gothic inundation rolled from the walls of this city to the ſuburbs of Conſtantinople; and the Roman provinces were ravaged by the barbarians. At this time a ſuſpicion prevailed, that the Goths of Aſia had formed a ſecret and dangerous conſpiracy againſt the public ſafety. An order was promulgated that, on a ſtated day, the Gothic youth ſhould aſſemble in the capital cities of their reſpective provinces; and as a report was induſtriouſly circulated, that they were ſummoned to receive a liberal gift of land and money, the pleaſing hope allayed the fury of their reſentment, and perhaps ſuſpended the motions of the conſpiracy. On the appointed day, the unarmed crowd of the Gothic youth aſſembled in the ſquare, or forum; the ſtreets and avenues were occupied by the Roman troops; and the roofs of the houſes were covered with archers and ſlingers. At the ſame time in all the cities of the Eaſt, the ſignal was given of indiſcriminate ſlaughter; and the provinces of Aſia were delivered by the cruel prudence of Julius, who was maſter-general of the troops, from a domeſtic enemy, who, in a few months, might have carried fire and ſword from the Helleſpont to the Euphrates. At length the Goths ſubmitted to Theodoſius I., and were allowed by him to ſettle in Thrace and Mœſia, which two provinces had been almoſt depopulated by the frequent incurſions of the neighbouring barbarians, and the late deſtructive war. A numerous colony of the Viſigoths was ſettled in Thrace; the remains of the Oſtrogoths were planted in Phrygia and Lydia; their immediate wants were ſupplied by a diſtribution of corn and cattle; and their future induſtry was encouraged by an exemption from tribute for a certain number of years. Hopes were entertained that the manners of the barbarians would in time be poliſhed, and that their poſterity would be inſenſibly blended with the body of the Roman people. Notwithſtanding theſe flattering expectations, it was apparent to every diſcerning eye, that the Goths would long remain the enemies, and might ſoon become the conquerors of the Roman empire. As the impatient Goths could only be reſtrained by the firm and temperate character of Theodoſius, the public ſafety ſeemed to depend on the life and abilities of a ſingle man. He died in the month of January A.D. 395, and before the end of the winter of the ſame year, the Gothic nation was in arms. The interruption, or at leaſt the diminution, of the ſubſidy which the Goths had received from the prudent liberality of Theodoſius, was the ſpecious pretence of their revolt. Inſtead of being impelled by the blind and headſtrong paſſions of their chiefs, they were now directed by the bold and artful genius of Alaric. In the year 396 Alaric marches into Greece; and he haſtened to occupy the city of Athens, and the important harbour of the Piræus. Corinth, Argos, and Sparta yielded without reſiſtance to the arms of the Goths. From Thermopylæ to Sparta, the leader of the Goths purſued his victorious march, without encountering any mortal antagoniſts; and the Chriſtian faith, which he had devoutly embraced, taught him to deſpiſe the imaginary deities of Rome and Athens. In 397 Stilicho, the general of the Weſt, advanced to chaſtiſe the invaders of Greece. The ſkill and perſeverance of the Roman at length prevailed: and the Goths, after ſuſtaining a conſiderable loſs by diſeaſe and deſertion, gradually retreated to the lofty mountains of Pholoe, near the ſources of the Peneus, and on the frontiers of Elis; a ſacred country, which had formerly been exempted from the calamities of war. Their camp was immediately beſieged; and reduced to great diſtreſs by thirſt and hunger. A ſtrong line of circumvallation was formed to prevent their eſcape. Alaric was ſecret, prudent, and rapid in his operations: he immediately negotiated a treaty with the miniſters of Conſtantinople; and Stilicho was compelled to retire from the dominions of Arcadius; and he reſpected, in the enemy of Rome, the honourable character of the ally and ſervant of the emperor of the Eaſt. Alaric is declared maſter-general of the Eaſtern Illyricum: and the uſe to which he applied his new command diſtinguiſhes the firm and judicious character of his policy. He iſſues his orders to the four magazines of offenſive and defenſive arms, Margus, Ratiaria, Naiſſus, and Theſſalonica, to provide his troops with an extraordinary ſupply of ſhields, helmets, ſwords, and ſpears. With the unanimous conſent of the barbarian chieftains, the maſter-general of Illyricum was elevated, according to ancient cuſtom, on a ſhield, and ſolemnly proclaimed king of the Viſigoths. Thus armed with double power, and ſeated on the verge of the two empires, he amuſed the two emperors Arcadius and Honorius, till he declared and executed his reſolution of invading the dominions of the Weſt. He was tempted by the fame, the beauty, and the wealth of Italy, which he had twice viſited; and he ſecretly aſpired to plant the Gothic ſtandard on the walls of Rome, and to enrich his army with the accumulated ſpoils of three hundred triumphs. Alaric loſes no time in executing his purpoſe of invading Italy, and advances, againſt much oppoſition, towards the capital of the empire. It was in the year 400 that he firſt entered Italy, making dreadful ravages in his progreſs. His march, probably from Theſſalonica, through the warlike and hoſtile country of Pannonia, as far as the foot of the Julian Alps; his paſſage of thoſe mountains, which were ſtrongly guarded by troops and entrenchments; the ſiege of Aquileia, and the conqueſt of the provinces of Iſtria and Venetia, appear to have employed a conſiderable time. In the year 403, Alaric approached Milan, and the emperor Honorius, dreading his arrival, fled to Ravenna. Stilicho, however, prepared to march againſt the enemy, whom he found encamped at Pollentia, on the Tanaro, in Piedmont. While the

Chriſtian Goths were devoutly celebrating Eaſter, they were attacked by Stilicho, and after a very ſevere engagement, they retreated from the field of battle, after the total defeat of the infantry, with their cavalry entire, under the command of Alaric, who poſſeſſed a mind, that was invincible and ſuperior to misfortune, and that derived new reſources from adverſity. The Gothic ſovereign, wiſhing to diſtinguiſh his retreat by ſome illuſtrious exploit, attacked Verona, but in the battle that enſued he ſuffered a defeat no leſs diſaſtrous than that at Pollentia. In the year 408 Alaric marched again towards Rome; with bold and rapid marches he paſſed the Alps and the Po; haſtily pillaged the cities of Aquileia, Altinum, Concordia, and Cremona; increaſed his forces by the acceſſion of 30,000 auxiliaries; and, without meeting a ſingle enemy in the field, advanced as far as the edge of the moraſs, which protected the impregnable reſidence of the emperor of the Weſt. He ſoon after pitched his camp under the walls of Rome. A ranſom having being offered and accepted, he raiſes the ſiege A.D. 409. Alaric's next attack was directed againſt the port of Oſtia, one of the boldeſt and moſt ſtupendous works of Roman magnificence; and as ſoon as he was in poſſeſſion of this important place, he ſummoned the city to ſurrender at diſcretion; but he contented himſelf with ſuperſeding Honorius, and beſtowing the purple on Attalus, prefect of the city. Attalus was ſoon after degraded, and his degradation was followed by the third ſiege and ſack of Rome, Aug. 24, A. D. 410. At the hour of midnight the Salarian gate was ſilently opened, and the inhabitants were awakened by the tremendous ſound of the Gothic trumpet. Eleven hundred and ſixty-three years after the foundation of Rome, the Imperial city, which had ſubdued and civilized ſo conſiderable a part of mankind, was delivered to the licentious fury of the tribes of Germany and Scythia. After ſix days' pillage and devaſtation, the victorious Goths evacuated Rome, and their intrepid leader advanced into Campania, and having ravaged that and the neighbouring provinces of Lucania, Samnium, Apulia, and Calabria, he approached the ſtraits of Sicily, with a deſign to paſs over into that iſland, and thence into Africa; but he was ſeized in the neighbourhood of Rhegium with a fit of illneſs, of which he died in a few days. (See ALARIC.) He was ſucceeded in the Gothic throne by his brother-in-law Ataulphus, or Adolphus, who concluded a peace with the empire, and marched into Gaul A. D. 412. Being driven out of Gaul A. D. 415, he retired to Spain, where he was ſoon after aſſaſſinated. Jingeric, his ſucceſſor on the Gothic throne, ſhared the ſame fate. After his death the free choice of the nation beſtowed the Gothic ſceptre on Vallia or Wallia, who concluded a peace with the Romans, and commenced a ſanguinary, but ſucceſsful war with the barbarians, who had ſettled in Spain. His victorious Goths, A. D. 419, forty-three years after they had paſſed the Danube, were eſtabliſhed, according to the faith of treaties, in the poſſeſſion of the ſecoud Aquitain, a maritime province between the Garonne and the Loire, under the civil and eccleſiaſtical juriſdiction of Bourdeaux. The Gothic limits were afterwards enlarged by the additional grant of ſome neighbouring dioceſes; and the ſucceſſors of Alaric fixed their royal reſidence at Thoulouſe. Thus, about the ſame time, in the laſt year of the reign of Honorius, the Goths, the Burgundians, and the Franks, obtained a permanent ſeat and dominion in the provinces of Gaul. Vallia was ſucceeded by Theodoric, who firſt made war with the Romans, and gained ſeveral places in Gaul belonging to them, and afterwards concluded a peace with them. The Goths continued quiet in the countries that had been allotted them in Gaul for the ſpace of ten years, or till the year 436, when, the Romans being engaged in a war with the Burgundians, Theodoric availed himſelf of that opportunity to enlarge his dominions. At length the Gothic king made peace with the Romans; and in the year 453 engaged by an alliance with them to aſſiſt them againſt the Huns, who had entered Gaul. Thoriſmund, his ſon and ſucceſſor, breaks with the Romans; but his brother Theodoric, who next occupied the Gothic throne, and who was eminently diſtinguiſhed by his talents and attainments, cultivated the friendſhip of the Romans, and contributed by his martial exploits to the ſupport of the Roman empire. Theodoric entered Spain with a large army of Goths and Burgundians: and having almoſt reduced the Suevians in Galicia, A. D. 457, he paſſed from thence into Luſitania, and reduced ſeveral places. Upon his return to Gaul, he took ſeveral cities belonging to the Romans, but was at length checked in his career and defeated by Ægidius, commander in chief of the Roman forces in that country. In Spain the Goths were more ſucceſsful than they were in Gaul, and became maſters of the greater part of the country. Under Euric, who aſcended the throne A. D. 466, the Goths drove the Romans out of Spain; and all the provinces, except Galicia, and part of Luſitania, which were ſubject to the Suevians, acknowledged him for their king, who reſiding at Thoulouſe, governed them by his lieutenants. Euric, having alſo made himſelf maſter of the beſt part of Gaul, compriſing the whole tract between the Rhone and the Loire, and of the greateſt part of Spain, was ſtill deſirous of reducing the remaining parts of both countries, when his death at Arles, A. D. 484, put a ſtop to his great deſigns. Euric is ſaid to have been the firſt who gave written laws to the Goths, for till his reign they had been governed by cuſtoms only; and for this purpoſe he employed Leo, his prime miniſter, one of the moſt learned men, and beſt civilians of that period. Theſe laws were called the "Theodorician" laws; and were obtruded by Euric upon the people of Gaul and Spain, who had been long accuſtomed to the Roman laws; but Alaric, his ſon and ſucceſſor, reſtored the Roman laws to their former authority, and cauſed them to be obſerved throughout his dominions. About this period the kingdom of the Viſigoths in Gaul terminated; and they, being driven from thence, fixed their royal ſeat at Toledo, in Spain. (See VISIGOTHS.) For the hiſtory of the Oſtrogoths; ſee OSTROGOTHS. Under Theodoric, who, A. D. 493, cauſed himſelf to be proclaimed by his Goths king of Italy, and was acknowledged as ſuch by the emperor Anaſtaſius, the ſucceſſor of Zeno, Theodoric ſecured his new kingdom by alliances with neighbouring powers: he quartered all his Goths in the caſtles and ſtrong holds, with their officers who were to command them in time of war, and govern them in time of peace; he retained the Roman laws, the ſame form of government, the ſame diſtribution of provinces, the ſame magiſtrates and dignities; and, beſides, according to the cuſtom of the Goths, he appointed for each city inferior judges, diſtinguiſhed by the title of counts, who were to adminiſter juſtice, and decide all diſputes; and in this reſpect the polity of the Goths, as Grotius obſerves, far excelled that of the Romans. Thus Italy, from the dominion of the Romans, fell under that of the Goths, almoſt without any perceptible change. See THEODORIC.

At ſubſequent periods attempts were made to recover the country from ſubjection to their government; particularly in the reign of Juſtinian. Under the weak reign of Theodatus, the Gothic king of Italy, Beliſarius invaded Italy, entered Rome A. D. 536, and reduced Naples A. D. 537. He defended Rome againſt the whole army of the

Goths, who beſieged it A. D. 537, and continued it above a year till their final departure. During this ſiege, which was raiſed in March, A. D. 538, one-third of their enormous hoſt was deſtroyed in frequent and bloody combats under the walls of the city, and the evils of famine and peſtilence were aggravated by their own licentiouſneſs, and the unfriendly diſpoſition of the country. Vitiger, their king, retired for ſhelter within the walls and moraſſes of Ravenna. At length Beliſarius beſieged the city, and took it in the latter end of the year 539. The ſubmiſſion of the capital was imitated in the towns and villages of Italy; and the independent Goths who remained in arms at Pavia and Verona, were ambitious only to become the ſubjects of Beliſarius. But his inflexible loyalty rejected, except as the ſubſtitute of Juſtinian, their oaths of allegiance. In the year 540, the Goths revolted, and Totila, the nephew of their late king, undertook the reſtoration of the kingdom of Italy. His firſt movements were rapid and ſucceſsful; and after reducing by force, or treaty, the towns of inferior note in the midland provinces of Italy, Totila proceeded, A. D. 546, to encompaſs Rome, and to ſtarve its inhabitants. Famine had relaxed the ſtrength and diſcipline of the garriſon, and Rome was taken by the Goths in December, A. D. 546. After the departure of Totila, it was recovered by Beliſarius in February, A. D. 547. (See BELISARIUS.) When Totila returned to avenge the injury and diſgrace, the Goths were thrice repulſed; they loſt the flower of their troops; the royal ſtandard had almoſt fallen into the hands of the enemy, and the fame of Totila ſunk, as it had riſen, with the fortune of his arms. Rome was again taken by the Goths, A. D. 549. Juſtinian made great preparations for the Gothic war, the conduct of which was committed to Narſes, who defeated Totila in a bloody engagement, July, A. D. 552, and Totila himſelf was ſtruck through the body with a lance. Narſes then proceeded to the conqueſt of Rome; and Juſtinian once more received the keys of the imperial city, which, under his reign, had been *five* times taken and recovered. The laſt king of the Goths was Teias, who was unanimouſly choſen to ſucceed and revenge their departed hero, March, A. D. 553. Sixty days were conſumed in diſtant and fruitleſs combats, between the Gothic and Roman armies, but at length, after an engagement of many hours, Teias fell, and his head, exalted on a ſpear, proclaimed to the nations, that the Gothic kingdom was no more. After a reign of 60 years, the throne of the Gothic kings was filled by the exarchs of Ravenna (ſee EXARCH); and the remains of the Gothic nation evacuated the country or mingled with the people. (Anc. Un. Hiſt. vol. xvii. Gibbon's Hiſt. vol. vii. paſſim.)

The Goths ſpread themſelves very widely in their various migrations, and formed part of the population of the ſeveral nations of Europe. In England the Celtic population was ſucceeded by the Gothic, and about two-thirds of England were poſſeſſed by the Belgic Goths. (See BELGÆ and ENGLAND.) About the time that the Belgæ ſeized on the ſouth of England, it appears that a hundred Gothic tribes paſſed to the ſouth of Ireland. (See IRELAND.) In France, or Gaul, the Goths, or warlike German tribes, under the denomination of Belgæ, ſeized on a third part of the country into which they introduced the Gothic language and manners. (See BELGÆ and GAUL.) The original population of the Netherlands was Celtic; but it was afterwards ſupplanted by the Belgæ. (See BELGÆ and NETHERLANDS.) In Germany, the Scythians or Goths, proceeding either from Scandinavia, or, as others ſay, from their original ſeats on the Euxine, expelled the Cimbri and Fins, and theſe, intermixed with the German nations, deſtroyed the Roman empire in the weſt. (See GERMANY, and the preceding part of this article.) Pruſſia appears to have been peopled by the Peucini and Æſtii, Gothic tribes bordering on the Venedi, who were Slavonians. (See PRUSSIA.) The Vandals, who conquered Spain in the fifth century, were ſubdued by the Viſigoths under Euric, who founded the modern kingdom of Spain. (See SPAIN.) The original population of Turkey in Europe chiefly ſprung from the ancient Scythians on the Euxine, the progenitors of the Dacians, Thracians, &c. and even of the Greeks. The regions of Turkey in Aſia were peopled by Scythic nations, intermixed with a few Aſſyrians from the ſouth. (See TURKEY.) The Batavi of Holland were the moſt northern people of Belgic Gaul, and without doubt a German or Gothic progeny. (See BATAVI, GAUL and HOLLAND.) The Cimbri or northern Celts, who originally peopled Denmark, were expelled by the Goths, if they were not, as ſome conceive, tribes of the ſame nation; and the Fins or Laps of Norway, which, with Sweden, conſtitutes the ancient Scandinavia, were driven to the northern extremities by the Gothic invaſion. (See DENMARK, NORWAY, SCANDINAVIA, and SWEDEN.) The Helvetians, or original Swiſs, are ſuppoſed by ſome writers to have been Celts; but others, with greater probability, conſider them as a Gothic race, or very ancient colony of Germans.

It has been a general opinion, ſtrenuouſly maintained by Cluverius and Pelloutier, and adopted by Mallet in his "Northern Antiquities," that the Gothic and Celtic nations were the ſame; but the ingenious Engliſh tranſlator of Mr. Mallet's "Northern Antiquities" has produced a variety of teſtimonies from ancient authors, to prove that the Celtic and Teutonic or Gothic nations were, *ab origine*, diſtinct, and that they differed conſiderably in perſon, manners, laws, religion, and language. The former were the anceſtors of the Gauls, Britons, and Iriſh; and the Germans, Saxons, and Scandinavians derived their origin from the latter. The Celtic tribes were probably the firſt that travelled weſtward; and the Goths, or Getæ of the ancients, who emigrated at different times from the eaſtern countries after them, might borrow ſome of their opinions and practices, which will account for the reſemblance that has been obſerved between them, without admitting that they were deſcended from them, or that they ſhould be conſidered as the ſame people. In the ſame way we may account for thoſe relics both of Celtic and Gothic ſuperſtitions, which are diſcernible in Gaul and Britain, and many other countries, the inhabitants of which derive their deſcent equally from the Celts and Goths, who were at different times maſters of theſe kingdoms, and whoſe deſcendants are now blended together; thus, the firſt inhabitants of Gaul and Britain being of Celtic race, followed the Druidical ſuperſtition. The ancient Germans, Scandinavians, &c. being of Gothic race, profeſſed that ſyſtem of polytheiſm which was afterwards delivered in the Edda; and the Franks and Saxons, who afterwards ſettled in Gaul and Britain, being of Gothic race, introduced the polytheiſm of their own nation, which was in general the ſame that prevailed among all the other Gothic or Teutonic people. See, however, the article GOTHIC *language*, where the original identity of the Celts and Goths is maintained partly by general reaſoning, and partly by etymological inveſtigation.

GOTLUNDA, in *Geography*, a town of Sweden, in Nericia; nine miles N. N. E. of Orebro.

GOTOMB, a town of Poland, in the palatinate of Lublin; 28 miles N. W. of Lublin.

GO-TON, a town of China, in the province of Se-tchuen; 48 miles N. W. of Ou-mong.

GOTSEELA, a town of Bengal; 48 miles W. of Midnapour.

GOTTA, or Gotto *Iſlands*, a cluſter of ſmall Japaneſe iſlands. N. lat. 30° 40′. E. long. 131° 40′.

GOTTAUL, a town of Bengal; 33 miles S. of Burdwar. N. lat. 22° 42′. E. long. 88° 5′.

GOTTESBERG, a town of Sileſia, in the principality of Schweidnitz, near which are two mines, one of gold, not now worked, and another of coals. The manufacture of this town conſiſts of knit worſted ſtockings. It contains two churches; 12 miles S. W. of Schweidnitz. N. lat. 50° 35′. E. long. 15° 54′.

GOTTESGAB, a town of Bohemia, in the circle of Saatz. N. lat. 30° 22′. E. long. 12° 54′.

GOTTI, Vincent-Lewis, in *Biography*, was born at Bologna in the year 1664. At ſixteen years of age he embraced the eccleſiaſtical life among the Dominican monks, and when he had completed his courſe of philoſophy at Bologna, he was ſent to ſtudy theology for four years at Salamanca in Spain. Upon his return to Italy in 1688, he was appointed profeſſor of philoſophy in the univerſity of Bologna; and ſoon recommended himſelf by his talents and virtues to the poſts of prior and provincial of his order. In 1728, pope Benedict XIII. raiſed him to the dignity of the purple; and three years afterwards appointed him member of the congregation for examining biſhops. So highly was he eſteemed, that in the laſt conclave, which was held during his time, he had the ſuffrages of a great number of the college for his being raiſed to the papal throne. He died at Rome in 1742, in his 79th year. His works, which are much valued by the Catholics, particularly by thoſe in Italy, diſplay conſiderable erudition and abilities. Of theſe the principal are "De vera Chriſti Eccleſia," in three volumes; "Theologia Scholaſtico-dogmatica, juxta Mentem divi Thomæ Aquinatis, &c." in ſix volumes 4to.; "Colloquia Theologica-polemica, in tres claſſes diſtributa, &c." 4to.; "De Eligenda inter Diſſidentes Chriſtianos Sententia," written in anſwer to a piece with the ſame title, by the celebrated John le Clerc; and an elaborate work in defence of the truth of the Chriſtian religion againſt Atheiſts, Idolaters, Mahometans, Jews, &c. in 12 volumes. He was employed at the time of his death in writing "A Commentary on the book of Geneſis." Moreri.

GOTTIGNIES, Giles-Francis, was born at Bruſſels in the year 1630, and entered into the order of the Jeſuits at Mechlin in 1653, whence he was ſent to Rome, to purſue his theological ſtudies; here he ſpent the reſt of his life employed in teaching the mathematics, and writing different works in that ſcience. He died in 1689, when he was about ſixty years of age. He was a conſiderable mathematician: a great lover of pure geometry, and had a diſtaſte to the algebraic method of reſolving problems; his works are very numerous, and have been highly commended for perſpicuity and preciſion. They relate to arithmetic and geometry; to the various parts of aſtronomy, and other branches of ſpeculative and practical mathematics. Moreri.

GOTTINGEN, or Goettingen, in *Geography*, a town of the kingdom of Weſtphalia, and principal place of a diſtrict, named from it, is ſituated in a ſpacious, pleaſant, fertile valley, on a canal, branching from the river Leine, and dividing the town into the New town and Marſch. The number of houſes is about 1000, containing about 8000 perſons; the ſtreets are large and paved; it has five pariſh churches, and one for Calviniſts; the Roman Catholics perform their religious ſervice in a private houſe. The town is governed by a provoſt, named by the ſovereign, burgo-maſters, and a ſynod choſen by the regency, aſſiſted by a council. The univerſity of Gottingen claims peculiar notice; it was founded in 1734 by George II, king of England, and conſecrated on the 17th of September 1737, and by the attention of its firſt curator, baron Munchauſen, it has riſen to diſtinguiſhed reputation. It has a ſplendid church, with its own paſtor; and it is accommodated with a ſtately edifice of ſtone, the ground-floor of which ſerves as a hall for public lectures, and the upper apartments are appropriated to the library, council-chamber, and other neceſſary purpoſes. Its library is very large and valuable, and it is called the "Bulowean," from a collection of about 10,000 volumes, with which it originated, bequeathed by baron Bulow for public uſe, and granted by his heirs to the univerſity. A royal ſociety of ſciences, founded in 1751, and a royal German ſociety, form part of the univerſity. It has likewiſe a fine obſervatory, erected on a tower on the ramparts, with a phyſic garden, anatomical theatre, &c. The territory belonging to the town is very conſiderable; 22 miles N. E. of Caſſel. N. lat. 51° 31′. E. long. 9° 52′.

GOTTO, a country of Africa, ſituated to the ſouth of Jinbali and Tombuctoo, and the river Niger or Joliba, about 15° N. lat., and from 0° to 2° E. long. It was formerly divided into ſeveral petty ſtates, under their own chiefs, but it is now under the government of a king. Its chief town is called Mooſſeeddoo, from the name of their firſt monarch.

GOTTOLENGO, a town of Italy, in the department of the Mela; 15 miles S. of Breſcia.

GOTTORP. See Sleswic.

GOTTSCHEE, a town of Middle Carniola; 20 miles S.S.E. of Laybach. N. lat. 45° 53′. E. long. 14° 48′.

GOTZEL, a town of Bavaria; 36 miles E. of Ratiſbon.

GOVAN, a town of Scotland, in Lanarkſhire; the population of which, in 1801, was 6701, of which 1314 were employed in trade and manufactures; four miles W. of Glaſgow.

GOVANDORE, a bay on the coaſt of Chili.

GOUANIA, in *Botany*, was named by Jacquin in honour of Anthony Gouan, a phyſician and celebrated botaniſt of Montpellier, where he has long filled the botanical chair, and, as far as we know, is ſtill living, though at a very advanced age. He was the friend and correſpondent of Linnæus, and is the author of a *Flora Monſpeliaca*, arranged according to what he himſelf calls a hybrid ſyſtem, the outlines being on the principles of Tournefort, the ſubordinate ſections taken from the Linnæan ſexual ſyſtem. This work appeared in 1765. He had previouſly, in 1762, publiſhed a *Hortus Monſpelienſis* according to the laſt-mentioned ſyſtem. Each work forms an octavo volume. They are chiefly remarkable for the ſecondary generic characters, taken from the habit, ſubjoined to the eſſential ones which are founded on the fructification. Profeſſor Gouan publiſhed alſo a folio volume of Obſervationes Botanicæ, with plates, illuſtrative of the plants of his neighbourhood; as well as a quarto in Latin and French on the methodical arrangement, and generic characters at length, of fiſhes.—Jacq. Amer. 263. Linn. Gen. 547. Schreb. 133. Mart. Mill. Dict. v. 2. Juſſ. 381. Lamarck. Illuſtr. t. 845.—Claſs and order, *Polygamia Monoecia*, or rather *Pentandria Monogynia*, Nat. Ord. *Dumoſæ*, Linn. *Rhamni*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, ſuperior, funnel-ſhaped, five-cleft; tube permanent; ſegments of the limb ovate, acute, ſpreading, deciduous. *Cor.* Petals five, oppoſite to the ſtamens, hood-ſhaped, elaſtic. *Stam.* Filaments five, awl-ſhaped, the length of the ſegments of the calyx, and alternate with them, inſerted into the tube; anthers roundiſh, incumbent, ſheltered by the petals. *Piſt.* Germen inferior, roundiſh; ſtyle awl-ſhaped, divided half-way down into three ſegments; ſtigmas obtuſe. *Peric.* Capſule with three angles, ſeparable into three parts, of one cell each, not burſting. *Seeds* ſolitary, ovate, compreſſed, poliſhed.—There are ſome male flowers, furniſhed with a ſtyle, but deſtitute of germen and ſtigma.

Eſſ. Ch. Calyx five-cleft. Petals five, hooded, covering the anthers. Style three-cleft. Capſule inferior, ſeparating into three ſingle-ſeeded parts.—Some flowers male.

Jacquin originally deſcribed two ſpecies, of which Linnæus adopted but one. Lamarck has added three more, all in our poſſeſſion, to which we are enabled to furniſh three non-deſcript ſpecies, making eight in all.

1. G. *domingenſis.* Linn. Sp. Pl. 1663. Lamarck Dict. v. 3, 4. (G. glabra; Jacq. Amer. 264. t. 179. f. 40. Lupulus ſylveſtris americana, &c. Pluk. t. 201. f. 4.)—Leaves ovate, pointed, ſerrated, nearly ſmooth. Wings of the fruit dilated, kidney-ſhaped.—Native of woods in Hiſpaniola and the Bahama iſlands. A climbing much branched *ſhrub,* the young branches downy, ending in long ſimple ſpiral tendrils. *Leaves* alternate, on ſhort hairy ſtalks, ovate, a little unequal, an inch and half long, bluntly ſerrated, furniſhed with a blunt entire point, and with ſeveral ſtraight parallel veins directed forward. The young leaves are rather downy, old ones nearly ſmooth. *Stipulas* ſmall, half arrow-ſhaped. *Flowers* in long terminal cluſters, ſmall, greeniſh and unornamental. *Capſules* of a light ſpongy texture, their central part as big as a ſmall pea, the wings thrice as long, ſpreading, pale brown, ſmooth and ſomewhat poliſhed. *Seeds* hard, of a ſhining brown.

2. G. *tomentoſa.* Jacq. Amer. 263. Linn. MSS. in Sp. Pl. (G. crenata; Lamarck Dict. v. 3. 5?)—"Leaves ovate, crenate, downy."—Native of woods in Hiſpaniola, climbing to the tops of lofty trees. *Jacquin.* Of this we have ſeen no ſpecimen. Jacquin ſays the *leaves* are four inches long. *Seeds* black and ſhining. Lamarck ſuppoſes his plant to be the ſame on account of the great ſize of its leaves, and he ſays it is diſtinguiſhed from all others by their crenatures. Jacquin deſcribes his as ſlightly crenate.

3. G. *cyclocarpa.*—Leaves elliptic-oblong, pointed, obſoletely ſerrated, roughiſh, naked on both ſides. Wings of the fruit narrow, orbicular.—Native, we believe, of the Weſt Indies. The very young *ſhoots* and *leaves* only are ſilky and ferruginous. The full-grown *leaves* are near three inches long and one broad, ſomewhat ovate, either almoſt entire, or furniſhed with ſhallow diſtant ſerratures, and a ſhort entire blunt point; they are green and quite naked on both ſides, but harſh to the touch on the upper ſurface. Veins diſtant. *Footſtalks, flowerſtalks,* and *ſtipulas* hairy. *Flowers* ſomewhat ſilky. *Fruit* orbicular at each ſide, each wing forming a hemiſphere, and not being much dilated.

4. G. *denticulata.*—Leaves ovate, pale and downy beneath, entire, with a finely-toothed point.—Gathered by the late Mr. Chriſtopher Smith in the iſland of Honimoa, Eaſt Indies.—The *leaves* are about an inch and half long, with ſtraight veins, connected by numerous minute reticulations, and are remarkable for the numerous little ſharp teeth which border their upper part and terminal point, while the reſt of their margin is entire. Their upper ſide is roughiſh to the touch, but green and naked; while the lower is hoary with very denſe ſhort down, the veins only being naked. *Stipulas* ſmall and deciduous. A ſimple curled *tendril* terminates each lateral branch, as in all the foregoing. *Flowers* in axillary downy cluſters, with lanceolate deciduous bracteas. The *fruit* we have not ſeen.

5. G. *mauritiana.* Lamarck Dict. v. 35.—Leaves ovate, pointed, variouſly ſerrated, downy on both ſides.—Native of the heights called the *Gol,* in the deſert, of the iſle de Bourbon, where it was gathered by Commerſon, and ſent to the botanic garden at Paris. The *leaves* are the ſize of the laſt, but green and clothed with ſilky down on both ſides. Their figure is ovate, rarely ſomewhat cordate, often unequal, ſharp-pointed, their margin ſingularly variable, being ſometimes nearly entire, having only ſcattered ſhallow ſerratures, ſometimes very deeply and doubly ſerrated, not unlike the Roman nettle, *Urtica pilulifera.* *Stipulas* ovate, acute, clothed with ſhining reddiſh ſilky hairs, as well as the young twigs and tendrils. The *fructification* is wanting in our ſpecimens. Lamarck ſays the *capſules* have rounded thin and membranous wings.

6. G. *tiliæfolia.* Lamarck Dict. v. 3. 5. (G. Stadtmanni; Willem. Herb. Maurit. 58?)—Leaves heart-ſhaped, bluntly pointed, ſmooth on both ſides, bluntly and ſlightly ſerrated. Native of the iſle de Bourbon, near *la Villebague.* Commerſon. The *ſtem* is much branched and divaricated, ſmooth, except the very young ſhoots. *Leaves* an inch or inch and half long, and nearly as broad, heart-ſhaped, with ſhallow ſerratures and a ſhort blunt point. They are light green and naked on both ſides, ſmooth above; minutely chagrined beneath. *Stipulas* glandular. *Flower-ſtalks* ruſty and downy. The *tendrils* become very thick and ſtrong by age.

7. G. *integrifolia.* Lamarck Dict. v. 3. 5.—Leaves ovate, bluntiſh, entire, ſmooth on both ſides. Stipulas awl-ſhaped. Long cultivated in the Paris garden, but its native country is not remembered. We have a ſpecimen from thence, deſtitute of *flowers* and *fruit,* yet we readily agree with Lamarck that there can be no doubt reſpecting its genus. The habit, ſtem, tendrils, folded young leaves, and their pale parallel veins, all indicate a *Gouania,* for no genus can be more natural than this. The *leaves* are uſually about an inch long, exactly ovate, (not oval) without any elongated point, though tipped with a gland; their margin quite entire, their midrib ſometimes ſlightly hairy at the back. *Stipulas* awl-ſhaped, deciduous. *Footſtalks* hairy only while young.

8. G. *ſmilacina.*—Leaves heart-ſhaped, minutely ſerrated, acute, ſomewhat hairy. Stipulas awl-ſhaped. Flower-ſtalks umbellated, ſcarcely ſo long as the leaves. Brought by the late ſir G. L. Staunton, Bart. we believe from the Braſils. The zig-zag *branches,* with ſmall heart-ſhaped *leaves,* and numerous axillary umbels of *flowers,* give it the aſpect of a *Smilax.* The *tendrils* grow from the firſt joint of each branch, and are elegantly ſpiral; ruſty and hairy, like the *flower-ſtalks* and *calyx.* The principal *leaves* are uſually about an inch long, green on both ſides, their ribs and veins always very hairy, their ſurface more or leſs ſo. *Stipulas* awl-ſhaped, hairy. S.

GOUAREC, in *Geography,* a town of France, in the department of the North Coaſts, and chief place of a canton, in the diſtrict of Loudeac; 24 miles S.W. of St. Brieuc. The place contains 678, and the canton 6,093 inhabitants, on a territory of 207½ kiliometres, in 5 communes.

GOUD, or GAUD. See WELD.

GOUDA, or TERGOUW, in *Geography,* a city of Holland, ſeated on a branch of the Rhine, called Iſſel, where it receives the Gouw, from which it derives its name. The great church of this town is one of the largeſt and handſomeſt in the country, and is particularly famous for its painted glaſs windows, which were executed principally by Theodore and Walter Crabeth of this town, and which are carefully preſerved. The town is advantageouſly ſituated, on account of the ſluices and canals, which are running ſtreams, and its convenient port on the Iſſel. It has five gates, and is ſo circumſtanced by reaſon of the ſluices, which may inundate the adjacent country, the breadth and depth of its ditches, and the ſtrong fortifications on the banks of the Iſſel, that it cannot eaſily be beſieged. Its chief trade conſiſts in cordage, cheeſe, and tobacco-pipes; and it has a regular communication by boats with Amſterdam, the Hague, Rotterdam, Utrecht, &c.; 22 miles S. of Amſterdam. N. lat. 52° 1′. E. long. 4° 36′.

GOUDHURST, a poſt-town of England, in the county of Kent, containing 1782 inhabitants; 11 miles S. of Maidſtone, and 44 S.E. of London.

GOUDOZ, a town of Aſiatic Turkey, in Natolia; 72 miles E.N.E. of Kiutaja.

GOUDIMEL, Claude, in *Biography*, one of the early and moſt celebrated compoſers of muſic to the metrical French tranſlations of the pſalms for the uſe of the Calviniſts. He was a native of Franche-Comté, who ſeems to have loſt his life at Lyons, on the day of the maſſacre of Paris, for having ſet to muſic the pſalms of Clement Marot. Goudimel has been much celebrated by the Calviniſts in France for this muſic, which was never uſed in the church of Geneva, and by the Catholics in Italy for inſtructing Paleſtrina in the art of compoſition, though it is doubtful whether this great harmoniſt and Goudimel had ever the leaſt acquaintance or intercourſe together. He ſet the "Chanſons Spirituelles" of the celebrated Marc-Ant. De Muret, in four parts, which were printed at Paris, 1555. We may ſuppoſe Goudimel, at this time, to have been a Catholic, as the learned Muret is never ranked among heretics by French biographers. Ten years after, when he ſet the pſalms of Clement Marot, this verſion was ſtill regarded with leſs horror by the Catholics than in later times; for the muſic which Goudimel had ſet to it was printed at Paris by Adrian Le Roy, and Robert Ballard, with a privilege, 1565. It was reprinted in Holland, in 1607, for the uſe of the Calviniſts, but ſeems to have been too difficult; for we are told by the editor of the pſalms of Claude le Jeune, which were printed at Leyden, 1633, and dedicated to the States-General, that, "in publiſhing the pſalms in parts, he had preferred the muſic of Claude Le Jeune to that of Goudimel; for as the counterpoint was ſimply note for note, the moſt ignorant in muſic, if poſſeſſed of a voice, and acquainted with the pſalm-tune, might join in the performance of any one of them; which is impracticable in the compoſitions of Goudimel, many of whoſe pſalms being compoſed in fugue, can only be performed by perſons well ſkilled in muſic.

The works of Goudimel, who was certainly the greateſt muſician in France, during the reign of Charles IX., are become ſo ſcarce, that his name and reputation are preſerved by Proteſtant hiſtorians, more in pity of his misfortunes, than by any knowledge of their excellence. With reſpect to his having been the maſter of Paleſtrina, that point will be diſcuſſed elſewhere.

The earlieſt mention of Goudimel, as a compoſer, that we have been able to diſcover, is in a work entitled "Liber quartus Eccleſiaſticarum Cantionum quatuor vocum vulgo Motetæ vocant," printed at Antwerp, by Suſato, 1554, eighteen years before his death. On ſcoring ſeveral of theſe motetæ, we found the harmony pure and correct, but conſtructed entirely on the principles of the eccleſiaſtical tones: probably before he became a diſciple of Calvin. The title of all his compoſitions may be ſeen in Draudius, Bibl. Claſſic. and Bibl. Exot. (See Franc, Claude le Jeune, and Paleſtrina.) The motets of Goudimel, in four parts, reſemble in gravity of ſtyle, ſimplicity in the ſubjects of fugue, and purity of harmony, the eccleſiaſtical compoſitions of our venerable countryman Bird.

GOODSWAARTE, in *Geography*, a ſmall iſland at the mouth of the Meuſe, S. of the iſland of Putten.

GOUEGA, a town of Africa, in Whidah; 10 miles W.S.W. of Sabi.

GOVENDING, a town of Bengal; 32 miles E. of Calcutta.

GOVERDAN, a town of Hindooſtan, in Mewat; 10 miles E.S.E. of Dig.—Alſo, a town in Oude, near the Dewah; 20 miles N. of Azimgur.

GOVERDUNPOUR, a town of Hindooſtan; 44 miles N. of Allahabad.

GOVERNDUNGURRY, a town of Hindooſtan, in Canara; 14 miles S.E. of Onore.

GOVERNMENT, a quality or office which gives a man power or right to command or rule over a place, a city, a province, a kingdom, or the like, either ſupremely or by deputation.

Government is either *general* and ſupreme, as that of a whole kingdom, empire, ſovereign ſtate, &c. or *particular* and ſubordinate; which, again, is ſubdivided into *civil*, *military*, and *eccleſiaſtical*.

Our cities, corporations, and boroughs, are uſually governed by mayors, with aldermen and common-councilmen.

Government is alſo uſed for the country, city, or place to which the power of governing or commanding is extended.

Government, again, is uſed for the manner or form of governing, *i. e.* for the police of a country, ſtate, &c.

In this ſenſe the various forms of government have generally received their denominations from the number of perſons to whom the ſupreme power has been entruſted. If it be in one perſon, it is called a *monarchy*, eſpecially if the chief magiſtrate lies under conſiderable reſtrictions, or governs by fixed and eſtabliſhed laws; whereas, if this ſingle perſon lie under fewer reſtraints, or directs every thing by his own will and caprice, the government is called *deſpotic*. If the ſupreme power be lodged in a limited number of perſons, the government is called an *oligarchy*, or *ariſtocracy*; and if all the citizens have an equal vote in making laws, and appointing magiſtrates, or the ſupreme power is lodged in the whole body of the people, it is called a *democracy* or *republic*. See theſe ſeveral articles.

Civil government and ſociety originate in the wants and fears of individuals, who, being naturally free, equal, and independent, aſſociate together, either by expreſs or tacit conſent, for the mutual preſervation of their lives, liberties, and eſtates, on this fundamental principle, that the whole ſhould protect all its parts, and that every part ſhould pay obedience to the will of the whole. However the ſeveral forms of government, that now ſubſiſt, actually begun, there is and muſt be in all of them a ſupreme, irreſiſtible, abſolute, uncontrouled authority, in which the *jura ſummi imperii*, or the rights of ſovereignty, reſide; and this authority is placed in thoſe hands, wherein, according to the opinion of the founders of ſuch reſpective ſtates, either expreſsly given, or collected from their tacit approbation, the qualities requiſite for ſupremacy, *viz.* wiſdom, goodneſs, and power, are the moſt likely to be found.

Individuals unite for mutual protection and benefit; and, therefore, the legiſlative and executive authority of government, originally derived from themſelves, ſhould be invariably directed to no other end but their ſafety and welfare; and that form of government is moſt eligible, which is beſt adapted to theſe purpoſes. Cicero declares himſelf of opinion, in his fragments De Rep. lib. ii. "eſſe optimam conſtitutam rempublicam, quæ ex tribus generibus illis, regali, optimo et populari, ſit modice confuſa." Of this kind is the Britiſh conſtitution, which lodges the executive power of the laws in a ſingle perſon, and the legiſlative in three diſtinct powers, entirely independent of each other; *viz.* the king; the lords ſpiritual and temporal, forming an ariſtocratical aſſembly; and the houſe of commons, freely choſen by the people, which renders it a kind of democracy; and each branch of this aggregate body, actuated by different views, and attentive to different intereſts, is armed with a negative power, ſufficient to repel any innovation which it ſhall think inexpedient or dangerous. Nothing can endanger or hurt the conſtitutional government of Britain, but deſtroying the equilibrium of power between one branch of the legiſlature and the reſt: for if ever it ſhould happen that the independence of any one of the three ſhould be loſt, or that it ſhould become ſubſervient to the views of the other two, there would ſoon be an end of our conſtitution: the legiſlature would be changed from that which was originally ſet up by the general conſent and fundamental act of the ſociety; and ſuch a change, however effected, is, according to Mr. Locke, at once an entire diſſolution of the bands of government, and the people are thereby reduced to a ſtate of anarchy, with liberty to conſtitute to themſelves a new legiſlative power. Locke on Government, book ii. chap. 19. Blackſt. Com. vol. i. Introd.

Another excellent writer gives a different account of the origin of civil government from that which has been above ſtated. Accordingly, he obſerves, that government, at firſt, was either patriarchal or military; *that* of a parent over his family, or of a commander over his fellow-warriors. Paternal authority, and the order of domeſtic life, ſays Dr. Paley, (Moral Philoſophy, vol. ii.) ſupplied the foundation of civil government. The condition of human infancy prepares men for ſociety, by combining individuals into ſmall communities, and by placing them from the beginning under direction and controul. A family contains the rudiments of an empire. The authority of one over many, and the diſpoſition to govern and to be governed, are in this way incidental to the very nature, and coeval, no doubt, with the exiſtence, of the human ſpecies. Beſides, a parent would retain a conſiderable part of his authority after his children were grown up, and had formed families of their own. This is the ſecond ſtage in the progreſs of dominion. The firſt was that of a parent over his young children; this that of an anceſtor preſiding over his adult deſcendants. The aſſociation, thus formed, would naturally be continued after the death of the original progenitor; and the members of it, accuſtomed to the benefits reſulting from it, might be induced to ſupply his place by a formal choice of a ſucceſſor, or they might voluntarily, and almoſt imperceptibly, transfer their obedience to one of the family, which had claimed their reſpect and confidence, or, again, they might receive with due deference a ſucceſſor, appointed by the firſt anceſtor. Thus we have a tribe or clan, incorporated under one chief, and fulfilling the purpoſes of civil union, without any other or more regular convention, conſtitution, or form of government than what has now been deſcribed. Two or three of theſe clans would frequently, by marriage, conqueſt, mutual defence, common diſtreſs, or ſome other accidental circumſtances, be united into a ſociety of larger extent. Another ſource of perſonal authority, which might extend, or ſuperſede, the patriarchal, is that which reſults from military arrangement. A popular and ſucceſsful leader, in every action of aggreſſion or defence, would gain a powerful and permanent influence among his followers. This advantage, added to the authority of the patriarchal chief, or favoured by any previous diſtinction of anceſtry, would enable the perſon who poſſeſſed it to acquire the almoſt abſolute direction of the affairs of the community; more eſpecially if he took care to aſſociate to himſelf proper auxiliaries, and to gratify or remove thoſe who oppoſed his pretenſions.

The cauſes which have contributed to introduce hereditary dominion, are principally the influence of aſſociation, which communicates to the ſon a portion of the reſpect that was paid to the virtues or ſtation of the father, the mutual jealouſy of other competitors, the greater envy with which all behold the exaltation of an equal, than the continuance of an acknowledged ſuperiority, and the number of adherents left by a reigning prince, who preſerve their own importance, merely by ſupporting the ſucceſſion of his children, and the apprehenſion of calamities that are incidental to conteſted elections. The ancient ſtate of ſociety in moſt countries, ſays our author, and the modern condition of ſome uncivilized parts of the world, exhibit that appearance, which this account of the original of civil government would lead us to expect. The earlieſt hiſtories of Paleſtine, Greece, Italy, Gaul, and Britain, inform us that theſe countries were occupied by many ſmall independent nations, reſembling thoſe which are now found among the ſavage inhabitants of North America, and upon the coaſt of Africa. This theory, it is added, affords a preſumption, that the earlieſt governments were monarchies, becauſe the government of families, and of armies, from which, according to the preceding ſtatement, civil government derived its inſtitution, and probably its form, is univerſally monarchical.

Our readers will obſerve that this theory is very different from ſir Robert Filmer's patriarchal ſcheme, now, indeed, almoſt forgotten and ſcarcely deſerving to be recorded; the refutation of which conſtitutes the firſt part of the admirable Locke's Treatiſe on Government. According to this ſcheme, all government is abſolute monarchy, which the author founds on this previous principle, that no man is born free. The abſolute ſovereignty of Adam was the reſult of a divine appointment and donation, and this ſovereignty has been regularly conveyed by a divine hereditary right to all ſucceeding monarchs. The notion, that kings reign by a *divine right*, independently of the deſignation of the people, and not accountable to them for the exerciſe of their power, abſurd as it will now very generally be thought, was, however, for a long time not only admitted, but prevalent even in this country. It is ſtrongly inculcated in the Homilies of our eſtabliſhed church, and was ſtrenuouſly maintained by ſeveral of its reſpectable divines. Dr. Tillotſon, enlightened and excellent as he was in other reſpects, could not, in the middle part of his life, emancipate himſelf from the idea, that it was ſinful to reſiſt government, as is evident from his letter to lord Ruſſel. That power originates with the people was condemned as an abominable tenet by the famous Oxford decree of 1683; but this is a topic on which it is needleſs to enlarge.

In the moſt popular forms of government, ſays Dr. Paley, the phyſical ſtrength reſides in the governed; and it therefore becomes an inquiry of conſiderable importance, among politicians, what motives induce the many to ſubmit to the few. In the diſcuſſion of this queſtion our author diſtributes the ſubjects of a ſtate into three different claſſes, *viz.* 1. Thoſe who obey from prejudice, or who are determined by an opinion of *right* in their governors, which opinion is founded upon *preſcription*: this preſcriptive title, in hereditary monarchies, is corroborated, and its influence conſiderably augmented, by an acceſſion of religious ſentiments, and by that ſacredneſs which men are apt to aſcribe to the perſons of princes. 2. Thoſe who obey from reaſon, by a conſideration of the neceſſity of ſome government or other, and of the certain miſchief of civil commotions. 3. Thoſe who obey from ſelf-intereſt, and who are kept in order by a variety of conſiderations that immediately affect themſelves.

Concerning the moral obligation of ſubmiſſion to civil government, thoſe who adopt the principles of Mr. Locke, and many other political writers, allege a compact between the citizen and the ſtate, as the ground of the relation between them; and this compact binding the parties, like private contracts, reſolves the duty of ſubmiſſion into the univerſal obligation of fidelity in the performance of promiſes. This compact is either, 1. *Expreſs,* on the part of the primitive founders of the ſtate, who are ſuppoſed to have met together for the declared purpoſe of ſettling the terms of their political union, and a future conſtitution of government. The whole body is ſuppoſed to have unanimouſly conſented to be bound by the reſolutions of the majority; and that majority is ſuppoſed to have fixed certain fundamental regulations, and thus to have conſtituted, either in one perſon, or in an aſſembly, a *ſtanding legiſlature,* to which, under theſe pre-eſtabliſhed reſtrictions, the government of the ſtate was thenceforward committed, and whoſe laws the ſeveral members of the convention were, by their firſt undertaking, thus perſonally engaged to obey.—This tranſaction is ſometimes called the "Social compact," and theſe ſuppoſed original regulations compoſe what are meant by the "conſtitution," the "fundamental laws of the conſtitution;" and form, on one ſide, the "inherent indefeaſible prerogative of the crown," and, on the other, the unalienable "birthright" of the ſubject; *i. e.* a *tacit* or *implied* compact by all ſucceeding members of the ſtate, who, by accepting its protection, conſent to be bound by its laws. "This account of the ſubject," ſays Dr. Paley, "although ſpecious, and patronized by names the moſt reſpectable, appears to labour under the following objections; that it is founded upon a ſuppoſition falſe in fact; and leading to dangerous conſequences." No ſuch ſocial compact was ever really made, nor any ſuch original convention of the people ever actually held, or could be held in any country, antecedent to the exiſtence of civil government in that country. It is to ſuppoſe it poſſible to call ſavages out of caves and deſarts, to deliberate and vote upon topics, which the experience, and ſtudies, and refinements of civil life, alone ſuggeſt: therefore no government in the univerſe *began* from this original. At a *Revolution* ſome imitation of a ſocial compact may have taken place. The eſtabliſhment of the United States of North America bears the neareſt reſemblance of it. Should it be ſaid, that the original compact is not propoſed as a fact, but as a fiction, for the commodious explication of the mutual rights and duties of ſovereigns and ſubjects; to this repreſentation it may be replied, that the original compact, if it be not a fact, is nothing; it can confer no actual authority upon laws or magiſtrates, nor afford any foundation to rights, which are ſuppoſed to be real and exiſting. But in the books, and alſo in the apprehenſion of thoſe who deduce our civil rights and obligations *à pactis,* the original convention is appealed to, and treated of, as a reality.

Moreover, it is alleged, that the theory of government, which affirms the exiſtence and the obligation of a ſocial compact, leads to concluſions unfavourable to the improvement, and to the peace, of human ſociety. Upon this theory it may be preſumed that many points, called "fundamentals" of the conſtitution, were ſettled by a convention of the people, anterior to the eſtabliſhment of the ſubſiſting legiſlature, and which the legiſlature has no right to alter, or interfere with. This circumſtance affords a dangerous pretence for diſputing the authority of the laws. Hence aroſe the doubt, which ſo much agitated the minds of men in the reign of Charles II., whether an act of parliament could of right alter or limit the ſucceſſion of the crown. Beſides, if it be by virtue of a compact that the ſubject owes obedience to civil government, he ought to abide by the power of government which he finds eſtabliſhed, however abſurd or inconvenient it may be. Moreover, every violation of the compact on the part of the governor releaſes the ſubject from his allegiance, and diſſolves the government.

Dr. Paley, rejecting the intervention of a compact, as unfounded in its principle, and dangerous in the application, aſſigns for the only ground of the ſubject's obligation, "the will of God as collected from expediency." Accordingly the author reaſons in the following manner. It is the will of God that the happineſs of human life be promoted; civil ſociety conduces to that end; civil ſocieties cannot be upheld, unleſs in each, the intereſt of the whole ſociety be binding upon every part and member of it; and this ſtep of the argument conducts us to the concluſion, namely, that ſo long as the intereſt of the whole ſociety requires it, that is, ſo long as the eſtabliſhed government cannot be reſiſted or changed without public inconveniency, it is the will of God (which *will* univerſally determines our duty) that the eſtabliſhed government be obeyed; and no longer. This principle being admitted, the juſtice of every particular caſe of reſiſtance is reduced to a computation of the quantity of the danger and grievance on the one ſide, and of the probability and expence of redreſſing it on the other. If it be aſked, who ſhall judge of this? the anſwer is, "Every man for himſelf." In contentions between the ſovereign and the ſubject, the parties acknowledge no common arbitrator; and it would be abſurd to refer the deciſion to *thoſe* whoſe conduct has provoked the queſtion, and whoſe own intereſt, authority, and fate, are immediately concerned in it. From the ſubſtitution of "public expediency" into the place of all implied compacts, promiſes, or conventions whatſoever, our author infers, 1. That it may be as much a duty at one time to reſiſt government as to obey it, *viz.* when more advantage will in our opinion accrue to the community from reſiſtance, than miſchief. 2. That the lawfulneſs of reſiſtance, or the lawfulneſs of a revolt, does not depend alone upon the grievance which is ſuſtained or found, but alſo upon the probable expence and event of the conteſt. Hence thoſe who concerted the revolution in England were juſtifiable in their counſels. 3. That irregularity in the firſt foundation of a ſtate, or ſubſequent violence, fraud, or injuſtice in getting poſſeſſion of the ſupreme power, are not ſufficient reaſons for reſiſtance, after the government is once peaceably ſettled. 4. That reſiſtance is not juſtified by every invaſion of the ſubject's rights, or liberty, or of the conſtitution; by every breach of promiſe, or of oath; by every ſtretch of prerogative, abuſe of power, or neglect of duty on the part of the chief magiſtrate; unleſs theſe crimes draw after them public conſequences of ſufficient magnitude to outweigh the evils of civil diſturbance. 5. That no uſage, law, or authority whatever, is ſo binding, that it need or ought to be continued, when it may be changed with advantage to the community. 6. As all civil obligation is reſolved into expediency, what, it may be aſked, is the difference between the obligation of an Engliſhman and a Frenchman, or why is a Frenchman bound in conſcience to bear any thing from his king, which an Engliſhman would not be bound to bear, ſince the obligation of both is founded in the ſame reaſon? Although their conditions may differ, their *rights* ſhould ſeem to be equal; and yet we are accuſtomed to ſpeak of the rights as well as the happineſs of a free people, compared with what belong to the ſubjects of abſolute monarchies; and how, it may be reaſonably inquired, can this compariſon be explained, unleſs we refer to a difference in the compacts by which they are reſpectively bound? In order to obviate this difficulty, it is allowed that a Frenchman is in conſcience bound to endure many things from his prince, to which an Engliſhman would not be bound to ſubmit for the following reaſons; *viz.* becauſe the ſame act of the prince is not the ſame grievance where it is agreeable to the conſtitution, and where it infringes it; and becauſe redreſs in the two caſes is not equally attainable. The duty of obedience is defined by different boundaries, and the point of juſtifiable reſiſtance is placed at different parts of the *ſcale* of ſuffering—all which is ſufficiently intelligible without a ſocial compact. 7. The intereſt of the whole ſociety is binding upon every part of it. If we appeal to the Chriſtian ſcriptures with regard to the duty of civil obedience or the *extent* of our civil rights and obligations, Chriſtianity hath left us where ſhe found us; ſhe has neither altered, nor aſcertained it. The two paſſages to which writers have generally referred in their inveſtigation of this ſubject are Romans xiii. 1—7, and 1 Peter ii. 13—18. In order to comprehend the proper import of the inſtructions contained in theſe paſſages, there are two queſtions relating to the ſubject of civil obedience, which ſhould be conſidered, *viz.* whether to obey government be a moral duty and obligation upon the conſcience at all, and how far, and to what caſes, that obedience ought to extend? Theſe paſſages, it may be obſerved, inculcate the *duty*; but they do not deſcribe the *extent* of it. The due conſideration of this diſtinction is ſufficient to vindicate theſe paſſages of ſcripture from any explanation of them that ſhall favour an unlimited paſſive obedience. But admitting what many commentators have ſtated, that an opinion was privately cheriſhed by the firſt Chriſtians, which led them to conceive, that their converſion to Chriſtianity entitled them to new immunities, to an exemption as of *right* (however they might give way to neceſſity) from the authority of the Roman ſovereign; we are furniſhed with a ſtill more apt and ſatisfactory interpretation of the Apoſtle's words. The two paſſages apply with great propriety to the refutation of this error. Little need be added in explanation of particular clauſes. St. Paul has ſaid, "whoſoever reſiſteth the power, reſiſteth the ordinance of God." This phraſe, "the ordinance of God," is by many ſo interpreted as to authorize the moſt exalted and ſuperſtitious ideas of the regal character. But ſurely ſuch interpreters have ſacrificed truth to adulation. For, in the firſt place, the expreſſion, as uſed by St. Paul, is juſt as applicable to one kind of government, and to one kind of ſucceſſion, as to another,—to the elective magiſtrates of a pure republic, as to an abſolute hereditary monarch. In the next place, it is not affirmed of the ſupreme magiſtrate excluſively, that *he* is the ordinance of God; the title, whatever it imports, belongs to every inferior officer of the ſtate as much as to the higheſt. The divine right of *kings* is, like the divine right of *conſtables*, in the law of the land, or even actual and quiet poſſeſſion of their office; a right ratified, we humbly preſume, by the divine approbation, ſo long as obedience to their authority appears to be neceſſary or conducive to the common welfare. Princes are ordained of God by virtue only of that general decree, by which he aſſents, and adds the ſanction of his will, to every law of ſociety, which promotes his own purpoſe, the communication of human happineſs: according to which idea of their origin and conſtitution, and without any repugnancy to the words of St. Paul, they are by St. Peter denominated the "*ordinance of man.*" Paley, *ubi ſupra.* See KING, LAW, LIBERTY, MONARCHY, PARLIAMENT, PASSIVE *obedience*, &c.

GOVERNMENT, in *Grammar,* is underſtood of that conſtruction of nouns and verbs, wherein they require ſome alteration to be made in others joined or conſtructed with them.

Conſtruction is divided into two parts; that of *concord,* and that of government, called alſo *regimen.* See CONCORD and REGIMEN.

GOVERNOLO, in *Geography*, a town of Italy, in the department of the Mincio; 12 miles S. E. of Mantua.

GOVERNOR, an officer veſted by a king, or ſovereign prince, with the command and adminiſtration of a province, place, &c.

A governor repreſents the king; and not only commands the garriſon, troops, &c. but the citizens, &c. A governor of a fortified place was anciently required to hold out three attacks, before he ſurrendered.

GOVERNOR is alſo frequently uſed for a preſident or ſuperintendant.

Thus we ſay, the governor of the bank; the governor and directors of the South Sea company; the governor of an hoſpital, &c.

GOVERY, in *Geography*, a town of Hindooſtan, in the circar of Rajamundry; 10 miles W. N.W. of Rajamundry.

GOUF. See GOLF.

GOUFRE, in *Geography*, a town of Canada, in the river St. Lawrence; 50 miles E. of Quebec.

GOUGANE-BANRA, a lake of Ireland, in the county of Cork, not far from Inchigeele. The river Lee riſes in a mountain above this lake, through which it flows. It was formerly the reſidence of St. Fin-Bar, and is viſited by great numbers of pilgrims, whilſt its romantic beauties attract a few travellers, notwithſtanding the ruggedneſs of the road.

GOUGE, WILLIAM, in *Biography*, who flouriſhed in the former part of the ſeventeenth century, was born in the pariſh of Bow, in the year 1575. He was educated partly at St. Paul's ſchool, and partly at Eton, and, in 1595, he was elected to King's college, Cambridge. Here, in due time, he performed with much applauſe all the exerciſes required by the ſtatutes, and took his degrees. In 1607, he was admitted into orders, and in the following year obtained the rectory of Blackfriars, London. In this ſituation he continued during the remainder of his life, diſcharging the paſtoral functions with great diligence and fidelity, and ſetting before his pariſhioners an example worthy of imitation. The zeal with which he performed the duties of his office, led him to eſtabliſh a weekly lecture, which was frequented not only by his own people but by many of the London clergy, the members of the Inns of Court, and the more reſpectable and ſerious citizens. In 1628, he was admitted to the degree of doctor of divinity, and about the ſame period he became one of the truſtees of the ſociety that had united for the purpoſe of buying up impropriations, to beſtow them on ſuch unpatronized clergymen as were diſtinguiſhed for piety and other miniſterial qualifications, which occaſioned his being proſecuted in the ſtar-chamber. In 1653, he was nominated one of the aſſembly of divines, and was held in ſuch reputation by that body, that he was often called to fill the moderator's chair during his abſence. He was ſelected as a proper perſon to write notes on the bible, and took, for his ſhare of the work, from the beginning of the firſt book of Kings to that of Job. He died in the year 1653, ſoon after he had completed his 78th year. He had, for ſeveral years, been eſteemed the father of the London miniſters. In his deportment, he was modeſt, humble, and affable; he had a pious and benevolent ſpirit, and continued to preach as long as he had ſtrength to walk into the pulpit. Beſides the “Annotations” already referred to, Dr. Gouge publiſhed many other theological pieces, as “A Commentary on the Epiſtle to the Hebrews;” “An Expoſition of the Lord's Prayer;” “The whole Armour of God,” &c.

GOUGE, THOMAS, ſon of the preceding, was born at Bow, in the year 1605; and having, in his academical courſe, followed the ſteps of his father, he was firſt choſen fellow of his college, and afterwards preſented with a living at Colſden, near Croydon, in Surrey, where he continued but a ſhort time; and, in 1638, he undertook the more important charge of St. Sepulchre's pariſh, London. During a period of twenty-four years he diſcharged the duties of his profeſſion with the moſt exemplary zeal. Beſides preaching twice every Sunday, and often on week days, he viſited his flock, catechiſed their children, enquired into and relieved the wants of the poor, and deviſed plans for their employment. He is ſaid to have given the hint which produced the humane and benevolent inſtitutions of Mr. Firmin, which have been referred to in the memoir of that excellent citizen. When the act of Uniformity took place, he was too conſcientious to ſacrifice his principles on the ſhrine of power, and was ejected from his living. His time was now zealouſly devoted to acts of beneficence and charity. He employed his own fortune, which was conſiderable, in relieving the wants of his poorer brethren, who, on account of their non-conformity, were deprived of their means of ſubſiſtence; and he was a ſucceſsful applicant to the rich, from whom he received large ſums, which were applied to that humane purpoſe. In the year 1671, he ſet about a plan for introducing knowledge and religion into the different parts of Wales, which at that period were in the moſt deplorable darkneſs. He eſtabliſhed ſchools in different towns where the poor were willing that their children ſhould be taught the elements of learning, and he undertook to pay all the expences which were incurred in the outſet of the buſineſs. By degrees theſe ſchools amounted to between three and four hundred, and they were all annually viſited by Mr. Gouge, when he carefully enquired into the progreſs made by the young people, before whom he occaſionally preached in a ſtyle adapted to their age and circumſtances in life, until he was obliged to deſiſt by proſecutions carried on againſt him in the eccleſiaſtical courts. With the aſſiſtance of his friends, whoſe purſes were ever open at his command, he printed eight thouſand copies of the bible in the Welſh language, a thouſand of theſe were diſtributed freely among thoſe who could not afford to purchaſe them, and the reſt were ſent to the cities and chief towns in the principality, to be ſold at reaſonable rates. He procured likewiſe the church catechiſm, and other practical pieces, to be printed in the Welſh language, and diſtributed among the poor. To theſe and ſuch like charitable undertakings did Mr. Gouge devote his time, his talents, and his fortune, when precluded by the intolerance of the laws from officiating in the capacity of a preacher He was accuſtomed to ſay with pleaſure, “that he had two livings which he would not exchange for two of the greateſt in England.” Theſe were Wales, where he travelled every year to diffuſe the principles of knowledge, piety, and charity: and Chriſt's Hoſpital, where he catechiſed and inſtructed the children in the fundamental principles of religion. He died ſuddenly in 1681, in the ſeventy-ſeventh year of his age. His death was regarded as a public loſs. A funeral ſermon was preached on the occaſion by Dr. Tillotſon, afterwards archbiſhop of Canterbury; who, at the concluſion of an animated eulogium on his piety and virtue, obſerves, that “all things conſidered, there have not, ſince the primitive times of Chriſtianity, been many among the ſons of men, to whom that glorious character of the ſon of God might be better applied, that “he went about doing good.” And Mr. Baxter, in his Narrative of his own Life and Times, ſays of Mr. Gouge, “I never heard any one perſon, of whatever rank, ſort, or ſect ſoever, ſpeak one word to his diſhonour, or name any fault that they charged on his life or doctrine; no, not the prelatiſts themſelves, ſave only that he conformed not to their impoſitions; and that he did ſo much good with ſo much induſtry.” This eminent Chriſtian divine publiſhed a few practical pieces, of which the following may be mentioned; “The Principles of Religion Explained:” “A Word to Sinners:” “Chriſtian Directions to walk with God:” “The ſureſt and ſafeſt Way of Thriving, *viz.* by Charity to the Poor;” “The Young Man's Guide through the Wilderneſs of this World.” Gen. Biog. Neal's Hiſt. of the Puritans.

GOUGE, an inſtrument uſed by divers artificers; being a ſort of round, hollow chiſſel; ſerving to cut holes, channels, grooves, &c. in wood, ſtone, &c.

GOUGEON, JOHN, in *Biography*, a French ſculptor and architect in the reigns of Francis I. and his ſucceſſors, is reckoned the firſt who introduced a true taſte for ſculpture in France, and freed it from the barbariſm of former times. He was employed in many of the public works with which Paris began to be decorated in the reign of Francis I. Of theſe the moſt conſiderable is the fountain of the Nymphs, called the Innocents, finiſhed in the year 1550. Among the other remains of his workmanſhip is a tribune in the hall des Cent-Suiſſes, at the Louvre, enriched with ſculptures, and ſupported by four gigantic Caryatides. He was an able medaliſt, and ſtruck ſeveral pieces for Catharine de Medicis, which are ſought by the curious. He generally worked in ſmall, and there are no detached figures or groups by his hand. His reliefs are executed with taſte, his drapery is light and elegant, his figures graceful and flexible, but their attitudes ſomewhat forced. He was a Huguenot, and was ſhot as he was working on a ſcaffold, on the infamous St. Bartholomew's day, 1570. Gen. Biog.

GOUGH'S ISLAND, in *Geography*, a ſmall iſland in the Southern Atlantic ocean, diſcovered by captain Gough in 1715. It is very high land, in S. lat. 40° 15'. W. long. 81° 57'. Some doubt being entertained with reſpect to its true longitude, it was recommended to M. de la Perouſe to aſcertain its true poſition, as it lies in the way of ſhips going directly to India, or China, early in the ſeaſon, without touching at the Cape.

GOUJET, CLAUDE PETER, in *Biography*, was born at Paris in 1697. His father, a taylor by trade, in vain oppoſed his inclination for a ſtudious life. He was educated among the Jeſuits, and, having taken orders, became a canon of the church of St. Jacques de l'Hôpital in Paris. He was an aſſociate of ſeveral academies in France, and was generally eſteemed for his learning, and alſo on account of the mildneſs of his temper and the purity of his morals. He died in 1767, and had collected a library of ten thouſand well choſen volumes, which was the baſis of his numerous works. Of theſe, the following may be mentioned, “Vies des Saints," in two vols. 4to. "Supplement to Moreri's Dictionary," two vols. folio. "Bibliotheque des Ecrivains Eccleſiaſtiques," three vols. 8vo. "Diſcours ſur le Renouvellement des Etudes depuis le xiv Siècle." "De l'Etat des Sciences en France depuis la Mort de Charlemagne juſqu'à celle du Roi Robert." This diſſertation obtained for the author the prize of the Academy of Belles Lettres, and he was complimented by a deputation from that body, deſiring permiſſion to nominate him to the vacant place of the deceaſed abbé Vertot. Goujet was likewiſe author of "Bibliotheque Françoiſe, ou Hiſtoire de la Litterature Françoiſe," 18 volumes 12mo. which is reckoned his moſt valuable work. Moreri.

GOUJIN, in *Geography*, a town of Portugal, in the province of Beira; 12 miles S.W. of St. Joao de Peſqueira.

GOVINPOUR, a town of Hindooſtan, in Bahar; 26 miles S. of Bahar.—Alſo, a town of Bengal; 10 miles W. of Nuldingah.

GOULAMCONDA, a town of Hindooſtan, in the Myſore; 9 miles S. of Gooty.

GOULART, Simon, in *Biography*, a French Proteſtant divine, was born at Senlis in 1543. He began his ſtudies late in life, but by perſevering induſtry, he made a great proficiency in the learned languages, and was choſen paſtor of the church of which Calvin had been miniſter. Here he diſcharged the duties of his office with much diligence and ſucceſs, till within a few years of his death, which took place in 1628, when he was about 85 years of age. He edited many works, performing at the ſame time the buſineſs of a commentator. Among theſe were the "Works of Plutarch;" "St. Cyprian's Works;" "Seneca's Works," &c. He made a collection of "Remarkable Hiſtories" in 2 vols. 8vo., and wrote ſeveral pieces relating to the hiſtory of his own times. The moſt intereſting and curious of the latter deſcription is his "Collection of the moſt memorable events which occurred during the League, with notes and original documents," in ſix vols. 4to. Many of his pieces were anonymous, but to theſe he uſually affixed the initials S. G. S. ſignifying "Simon Goulart Senliſien." He had ſuch an extenſive acquaintance with the literature of his time, and knew ſo well to whom different publications, that were printed without the writer's name, were to be attributed, that Henry III. of France, being deſirous of knowing who was the author of a piece publiſhed under the aſſumed name of Stephanus Junius Brutus, and intended to propagate republican doctrines, ſent a perſon to Geneva to enquire into the matter of Goulart, but the latter refuſed to communicate the fact, for fear of expoſing the author to ſerious injury. Moreri. Bayle.

GOULDSBOROUGH Harbour, in *Geography*, a harbour of the United States of America, in the diſtrict of Main. N. lat. 44° 25'. W. long. 67° 53'.

GOULERGAUT, a town of Thibet; 28 miles S. of Deuprag.

GOULOUR, a town of Hindooſtan, in the circar of Sanore; 18 miles N. of Sanore.

GOULSTON, Theodore, in *Biography*, was the ſon of William, rector of Wymondham, and was born in Northamptonſhire. He became probationer fellow of Merton college, Oxford, in 1596: and, after applying himſelf to the ſtudy of phyſic in this univerſity, he practiſed for a time with conſiderable reputation at Wymondham and its neighbourhood. At length, after taking his doctor's degree in 1610, he removed to London, and became a fellow of the College of Phyſicians, and afterwards cenſor. He reſided in the pariſh of St. Martin's, near Ludgate, and was in great eſteem, as well for claſſical learning and theology, as for the practice of his profeſſion. He died in the year 1632; and by an article in his will teſtified ſuch regard to the intereſts of medicine, as entitles him to grateful commemoration. This was a bequeſt of 200 pounds, to purchaſe a rent charge for the maintenance of an annual pathological lecture within the College of Phyſicians, to be read by one of the four youngeſt doctors of the College. The public has been indebted on ſeveral occaſions to this inſtitution for ingenious diſſertations, delivered as Gulſtonian Lectnres; as thoſe of Dr. Muſgrave; Dr. Fordyce's Treatiſe on Digeſtion; &c.

Dr. Goulſton publiſhed the following works. "Verſio Latina et Paraphraſis in Ariſtotelis Rhetoricam." Lond. 1619, &c. "Ariſtotelis de Poetica Liber, Latine converſus et Analytica Methodo illuſtratus." Lond 1623. And after his death, his intimate friend Thomas Gataker, B. D. publiſhed his "Verſio, variæ Lectiones et Annotationes Criticæ in opuſcula varia Galeni." Lond. 1640. Aikin, Biograph. Mem. of Med.

GOUMEL, in *Geography*, a town of Africa, and capital of the country of the Foulahs, and reſidence of the Siratik. N. lat. 16° 16'. W. long. 11° 32'.

GOUNDA, a town of Hindooſtan, in Oude; 32 miles E.N.E. of Manickpour.

GOUPIA, in *Botany*. See Glossopetalum.

GOUPIL, James, in *Biography*, a phyſician of the ſixteenth century, was born in the province of Poitou. He acquired a conſiderable knowledge of the ancient languages, and afterwards directed his ſtudies to medicine, in the ſchools of Paris, where he graduated in 1547. His talents attracted the attention of the court, and he was appointed by Henry II. to the profeſſorſhip of medicine in the royal college, in 1555, a vacancy being occaſioned by the death of Sylvius. He is principally known as an editor and annotator of the writings of Dioſcorides, Alexander Trallian, Actuarius, and ſome other Greek writers: and he was engaged in the ſame labour, in reſpect to ſome of the writings of Hippocrates, when his ſtudies were terminated by death, in 1568. Eloy.

GOUR, called alſo *Lucknouti*, in *Geography*, the ancient capital of Bengal, ſuppoſed to be the "Gangia Regia" of Ptolemy, which ſtood on the left bank of the Ganges, about 25 miles below Rajemul. N. lat. 24° 53'. E. long. 88° 14'. It was the capital of Bengal 730 years B. C. and was repaired and beautified by Acbar, A. D. 1575, who gave it the name of "Jennuteabad," which name part of the circar in which it was ſituated ſtill bears. It was deſerted, as it is ſaid, on account of the inſalubrity of its air. Taking the extent of the ruins of Gour at the moſt reaſonable calculation, it is not leſs than 15 miles in length, along the old bank of the Ganges, and from two to three in breadth. Several villages ſtand on part of its ſcite; the remainder is either covered with thick foreſts, the habitations of tygers and other beaſts of prey, or become arable land, whoſe ſoil is chiefly compoſed of brick-duſt. The principal ruins are a moſque lined with black marble, elaborately wrought; and two gates of the citadel, which are grand and lofty. The bricks, which continue to be an article of merchandize, are of a peculiarly ſolid and durable texture.

GOURA, or Gura, a town of the duchy of Warſaw on the Viſtula; 12 miles from Warſaw.

GOVRA, a town of Perſia, in the province of Irak; 35 miles E. of Iſpahan.

GOURAY, a cape on the E. coaſt of the iſland of Jerſey; 4 miles E. of St. Helier.—Alſo, a town of France, in the department of the North Coaſts; 8 miles S. of Lamballe.

GOURD, in *Botany*. See Cucurbita.

Gourd, *Bitter*. See Colocynthis.

Gourd, *Indian tree*. See Crescentia.

Gourd, *Sour*. See Baobab.

Gourd-*worm*, the Engliſh name of a ſpecies of worm found in the inteſtines of ſeveral animals. It has this name from its reſembling the ſeed of the gourd in figure.

GOURDON, in *Geography*, a town of France, in the department of the Lot, and principal place of a diſtrict, 16 miles N. of Cahors. N. lat. 46° 44'. E. long. 1° 28'. The place contains 3703, and the canton 12,115 inhabitants, on a territory of 150 kiliometres, in 15 communes.

GOURDY, *Legs of Horſes*. See Grease.

GOUREY, in *Geography*, a town of Hindooſtan, in Oude; 10 miles N. W. of Lucknow.

GOURGONG, a town of Hindooſtan, in Allahabad; 10 miles N. of Corah.

GOURGOUTY, a town of Hindooſtan, in Golconda; 36 miles W. S. W. of Rachore.

GOURIN, a town of France, in the department of the Morbihan, and chief place of a canton, in the diſtrict of Pontivy; 26 miles W. N. W. of Pontivy. The place contains 3674, and the canton 11,819 inhabitants, on a territory of 242½ kiliometres, in five communes.

GOURMA, a town of Abyſſinia, on the coaſt of the Red ſea. N. lat 14° 52'.

GOURMUNGUL, a town of Hindooſtan, in Golconda; 12 miles S.W. of Malkar.

GOURMELEN, Etienne, in *Biography*, was a native of Brittany, and was ſent at an early age to Paris, where he ſtudied ſurgery, and afterwards medicine; in the latter of which he took the degree of doctor in the year 1559, and was elected dean of the faculty in November, 1574. Surgery, however, continued to be the favourite object of his attention, and he was appointed by Henry III. profeſſor of ſurgery in the Royal College in the year 1588. But he did not long fill his chair, for he died in 1594. His writings, which were valuable in their day, have now loſt their intereſt, in conſequence of the great improvements of modern ſurgery: they conſiſt of a "Synopſis Chirurgiæ," printed in 1566, and afterwards tranſlated into French;—a Latin tranſlation of Hippocrates "De Alimento," with a commentary;—and a treatiſe, entitled "Chirurgiæ Artis ex Hippocratis et Veterum decretis ad rationis normam redactæ, Libri tres," 1580. Eloy. Dict. Hiſt.

GOURNAI, Le Jars de, Mary, was born at Paris in 1506. She was, while very young, deprived of her father, and acquired an adoptive one in the celebrated Michael Montagne, who became the object of her enthuſiaſtic admiration. After the death of Montagne ſhe became heireſs of his writings, and publiſhed an edition of his "Eſſays," dedicated to cardinal Richelieu. She had well improved the leſſons of youth, and was intimately acquainted with the learned languages. She maintained a correſpondence with many of the moſt eminent literary characters of the age, by ſome of whom ſhe was honoured with the title of the "Tenth Muſe;" by others ſhe was denominated the "French Syren;" it is not, however, improbable, that the uncommonneſs of female learning at that time in France, rather than the intrinſic merit of her writings, excited admiration. In her own language ſhe wrote a ſtiff and awkward ſtyle, and her taſte in reading was uſually turned to the compilations and commentaries of paſt ages. She paſſed her life in celibacy, contented with a ſmall penſion from the court, and much eſteemed by her particular friends, ſome of whom were perſons of high rank. She died at Paris in 1645, in her 79th year, and was honoured with many epitaphs from literary characters. Her works were collected in a quarto volume, under the title of "Les Avis ou les preſens de la Demoiſelle de Gournai." Her temper was apt to be violent, and ſhe was very reſentful of real or ſuppoſed injuries; by theſe means ſhe made herſelf many enemies, who attacked her in their writings, in which neither her perſon, nor the defects in her character were ſpared. Bayle. Moreri.

GOURNAY, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton in the diſtrict of Neufchatel, 24 miles E. of Rouen. N. lat. 49° 29'. E. long. 1° 47'. The place contains 3543, and the canton 11,301 inhabitants, on a territory of 180 kiliometres, in 19 communes.

GOURNEI, a town of Egypt, on the ſcite of the ancient Thebes.

GOUROCK. See Greenock.

GOURRI, a town of Abyſſinia; 35 miles S.W. of Aſſab.

GOURVILLE, John Herauld de, in *Biography*, born at Rochefoucauld in 1625, was taken by the celebrated duke of that title into his ſervice as valet de chambre, but in a ſhort time he became his confidential friend. He was patronized by the great Condè, and was employed by the ſuperinrendant Fouquet, in public buſineſs. So well did he approve himſelf to his employers for political talents and integrity that he was propoſed to the king as ſucceſſor to Colbert in the miniſtry. He died in 1705, leaving behind him "Memoirs of his Life from 1642 to 1698," in two volumes 12mo. Theſe memoirs are written with frankneſs and ſimplicity, in a lively, though incorrect ſtyle, and they contain many curious and well authenticated anecdotes of the miniſters and principal perſons of his time, of which, it is ſaid, Voltaire made much uſe. Moreri.

GOURY Pashnum, in *Natural Hiſtory*, a name given by the people of the Eaſt Indies to a kind of orpiment of a deep yellow colour, veined with red in ſeveral places, and in ſome with white. It is found principally at the bottoms of mountains. They calcine it ſeveral times, and afterwards give it internally after intermitting fevers, and uſe it externally in ointments for the itch.

GOUSSET, James, in *Biography*, was born at Blois in the year 1635. He was educated for the miniſtry, and was choſen paſtor of the Proteſtant church at Poitiers in the year 1662. He was thrice invited to undertake the profeſſorſhip of divinity at Saumur, but refuſed to quit his flock till compelled to become a fugitive from the kingdom, in conſequence of the revocation of the edict of Nantz. On this occaſion he took refuge in Holland, and afterwards was ſettled, as French miniſter, at Groningen, where he likewiſe exerciſed the offices of profeſſor of divinity, and of the Hebrew language in the univerſity of that city. He died there in 1704, in his ſixty-ninth year. His principal works were "Diſſertations in Controverſy with the Jews," 1699. "Commentarii Linguæ Hebraicæ," 1702, which form a valuable Hebrew dictionary, of which the beſt edition was publiſhed at Leipſic in 1743. "Diſſertationes in Epiſtolam Pauli ad Hebræos," &c. 1712. At his death he left behind him numerous MSS., among which are commentaries upon the whole of the ſacred ſcriptures. Moreri.

GOUST, Gout, a French term, for what the Italians call *guſto*, and we *taſte*.

GOUT, in *Medicine*, a diſeaſe principally characterized by inflammatory attacks of the joints, more eſpecially of the foot, which return at intervals, and are connected with derangement of the digeſtive organs. The term, however, includes ſuch a variety of morbid affections, in its extended ſenſe, that it is not eaſy to give a conciſe definition of it; and we muſt have recourſe to a more ample deſcription of thoſe affections, in order to convey a juſt notion of its ſignification.

The ancient phyſicians included all the varieties of inflammation, that are liable to occur in the joints, under the general term, *Arthritis*, (from ἄρθρος, *a joint*, with the termination *itis*, denoting inflammation,) for the diſtinctions, made by modern phyſicians, between the two modifications of inflammation in the joints, now denominated *gout* and *rheumatiſm*, had not then been attended to. The term *Arthritis*, however, was uſed both as a generic and ſpecific term, and ſignified, not only inflammation of the joints generally, but the ordinary form of gout by way of excellence. But the Greeks alſo gave ſpecific names to the varieties of arthritis, according to the particular joints which the diſeaſe occupied: thus, for the ordinary form of gout in the foot the term ποδάγρα, *podagra*, was employed, which alſo became a generic title; for gout in the hand, the word χειράγρα, *chiragra;* and for gout in the knee, γονάγρα, *gonagra;* and ſo on. Among the ſpecies of arthritis was alſo included the *iſchias*, *ſciatica*, or *hip-gout*, which is now deemed a ſpecies of rheumatiſm. Theſe terms the Romans adopted; and they are ſtill retained in medical language. Our vernacular term *gout*, which came to us probably through the French, *la goutte*, originated in the dark ages among the humoral pathologiſts, who conſidered the diſeaſe as ariſing from the ſlow depoſition of a morbid humour, *guttatim*, as it were, upon the joints; hence, the name *gutta*, or *drop*, was applied to the diſeaſe. This term, according to Du Cange, was uſed by Radulfus, a Dominican of the 13th century, who writes, "cum *gutta*, quam podagram vel arthreticam vocant, frequenter vexaretur." Muſgrave de Arthritide.

In conſequence of the various forms which gout aſſumes, phyſicians have divided it under two heads, *regular* and *irregular* gout, or, as ſome have termed it, *tonic* and *atonic* gout; the former occurring in the earlier periods of life, while the ſtrength or tone of the ſyſtem remains unbroken; the latter, after a certain degree of weakneſs, or atony of the conſtitution, has been produced by the frequent attacks of the diſeaſe, advanced age, or other cauſes. We ſhall firſt deſcribe the ſymptoms by which theſe forms of the diſeaſe are characterized, and afterwards ſtate the cauſes and method of treatment, together with the ſpeculations of pathologiſts, reſpecting the nature of the diſeaſe, beginning with an account of the paroxyſm of

Regular Gout.—It is an inflammatory affection of the joints of the foot, which conſtitutes what is called a fit or paroxyſm of the regular gout. This ſometimes comes on ſuddenly without any warning of its approach; but it is generally preceded by ſeveral ſymptoms, eſpecially by thoſe of indigeſtion, as heart-burn, flatulence, and heavineſs after meals, with eructations of acid or bitter matters, and ſome degree of languor and torpor of the body; but immediately before the fit the appetite is ſometimes unuſually ſharp. There is alſo often an unuſual coldneſs of the feet and legs for a few days preceding the fit, with the ceſſation of the perſpiration about the former; a frequent numbneſs, alternating with a ſenſe of prickling, along the whole of the lower extremities; occaſional cramps of the muſcles of the legs; and an unuſual turgeſcence of the veins, are occaſionally obſerved.

The attack is ſometimes felt in the evening, but more commonly about two or three o'clock in the morning; when the patient is awakened from a quiet ſleep by a pain affecting one foot, generally the ball or firſt joint of the great toe, but ſometimes the other parts of the foot, or the ankle. This pain is accompanied with more or leſs of chillineſs and ſhivering, which, as the pain increaſes, gradually ceaſe, and are ſucceeded by a hot ſtage of pyrexia, or ſymptomatic fever, which continues during the ſame time as the pain. The pain becomes by degrees more and more violent: at firſt it is attended with a ſenſation, as if warm water were poured upon the membranes affected, and is ſaid to reſemble the pain of a diſlocated joint; as it becomes ſevere it is ſometimes deſcribed as reſembling the pain of a tenſion, or laceration of the ligaments, ſometimes as like that from the gnawing of a dog, and ſometimes as a feeling of weight and conſtriction of the membranes of the part, which becomes ſo exquiſitely tender, as not to endure the weight of the bed-clothes, nor even the ſhaking of the room from a perſon walking briſkly in it. Hence, great reſtleſsneſs of the whole body, and eſpecially of the part affected, always accompanies the fit; the patient conſtantly changing his poſture, with a view to eaſe the pain, which, nevertheleſs, continues ſevere all the following day, until mid-night, after which it gradually remits; and about two or three in the morning, that is, after twenty-four hours from the firſt attack, it commonly ceaſes almoſt entirely; and this freedom, with the breaking out of a free perſpiration, allows the patient to fall aſleep. On waking, he finds the pain ſlight, and the part affected with ſome redneſs and ſwelling.

When a paroxyſm has thus come on, although the violent pain, after the period of twenty-four hours, be conſiderably diminiſhed, yet the patient is not entirely without pain. For ſome days he has a return every evening of pain and fever, which continue, with more or leſs violence, till morning. After continuing in this manner for ſeveral days, the diſeaſe ſometimes goes off entirely, not to return till after a long interval; and in ſuch caſes it generally leaves the perſon in very perfect health, enjoying greater eaſe and alacrity in the functions both of body and mind, than he had for a long time before experienced.

It often happens, however, that the diſeaſe does not thus ſpeedily quit the patient, eſpecially when he has previouſly ſuffered conſiderably from its attacks. For, inſtead of ceaſing altogether after a few days, it ſeizes the other foot in the ſame manner as it did the former, both in reſpect to the vehemence and duration of the pain. Moſt commonly the foot firſt affected becomes quite eaſy, in ſuch a caſe, and even as ſtrong and healthy as if it had not been diſeaſed; but ſometimes both feet are affected together, and with equal violence. When this happens, the ſucceeding exacerbations, as Sydenham remarks, are leſs regular both as to the time of coming on, and as to their continuance; but the pain always increaſes in the evening and remits in the morning; and what is called a fit of the gout, which goes off ſooner or later, according to the age and conſtitution of the patient, is made up of a number of theſe little fits. For when this diſeaſe laſts two or three months, it is not to be eſteemed one continued fit, but rather a ſeries or aſſemblage of ſmall fits, the laſt of which proves milder and ſhorter, until the whole is terminated. In ſtrong conſtitutions, and ſuch as have the gout ſeldom, the attack is commonly finiſhed in fourteen days; but in thoſe of advanced life, or who have frequent returns of the diſeaſe, theſe ſeries of fits will continue for two months; and in ſuch perſons as are more debilitated, either by age or the long continuance of the diſorder, it will not go off till the ſummer advances, (beginning, as is moſt common, in January, or early in February,) which ſeems to drive it away.

When the fit is going off, a violent itching ſeizes the foot, eſpecially between the toes, and the cuticle peels off. The appetite and ſtrength return ſooner or later, according to the greater or leſs ſeverity of the preceding fit, and the interval of health between the paroxyſms is generally nearly in the ſame ratio; *i. e.* longer in proportion to the greater violence of the laſt fit. At the beginning of the diſeaſe, Dr. Cullen obſerves, the returns of it are ſometimes only once in three or four years; but after ſome time the intervals become ſhorter, and the attacks become annual: afterwards they come twice each year, and at length recur ſeveral times during the whole courſe of autumn, winter, and ſpring; and as it happens that, when the fits are frequent, the paroxyſms become alſo longer, ſo, in the advanced ſtate of the diſeaſe, the patient is hardly ever tolerably free from it, except, perhaps, for two or three months in ſummer.

Before the diſeaſe becomes thus inveterate, however, it has gradually aſſumed other appearances, and attacked other parts of the body. At firſt it commonly affects one foot only; but afterwards every paroxyſm affects both feet, the one after the other, and then both together; and its changes of place, as it continues to recur, are not only from one foot to the other, but alſo from the feet into other joints, as the hands, wriſts, elbows, knees, &c.; ſo that there is ſcarcely a joint in the body that is not, on one occaſion or other, affected. It ſometimes ſeizes on two different joints at the ſame time; but more commonly it is ſevere in a ſingle joint only, and paſſes ſucceſſively from one joint to another; ſo that the patient's affliction is often protracted for a long time. The pains, indeed, are commonly leſs violent, in this ſtate of the diſeaſe, than they were at firſt; but, in addition to them, loſs of appetite, ſickneſs, and other ſymptoms of the atonic gout, now afflict him. Beſides, in the intervals between the firſt paroxyſms of the diſorder, the joints which had been affected were entirely reſtored to their former ſuppleneſs and ſtrength, and were free from pain or uneaſineſs, and all the functions of life were well performed. But in this protracted condition of the diſeaſe, the joints remain not only weak and ſtiff, after the termination of the fit, but they become at length ſo contracted and diſabled, that although the patient can ſtand, and perhaps walk a little, yet it is very ſlowly, and with great lameneſs and difficulty, ſo that he is ſcarcely able to move from room to room; and ſometimes the joints loſe their motion altogether.

In many perſons, though not in all, when the diſeaſe has frequently recurred, this immobility of the joints is farther increaſed by the formation of concretions, of a chalky appearance, upon the outſide of them, and for the moſt part immediately under the ſkin. The ſecretion or depoſition of this matter is characteriſtic of the diſeaſe, being the conſequence of gouty inflammation alone. It ſeems to be depoſited at firſt in a fluid form, but afterwards becomes dry and firm; in which ſtate the concretions have the appearance of a friable earthy ſubſtance, and have been called CHALK-*ſtones* (which ſee). From the inveſtigations of Dr. Wollaſton, however, and other modern chemiſts, it has been aſcertained that they contain no calcareous or earthy matter, but conſiſt of a neutral ſalt, formed by the combination of the lithic or uric acid, with the fixed alkali, ſoda,—conſtituting a lithate or urate of ſoda. Theſe concretions form principally about the joints of the toes and fingers, in little nodules, which Sydenham compares to crab's eyes; but ſometimes they appear about the larger joints, as the elbow and knee, occaſioning a whitiſh ſwelling almoſt as large as an egg, which becomes gradually inflamed and red. Mr. Watſon has related an example of a very extenſive depoſition of urate of ſoda, in a gouty man, who was a martyr to the diſeaſe. Chalk-ſtones not only enveloped the joints of his great toes, formed tumours upon his legs, and, being mixed with the ſynovia of the large joints, rendered this fluid as thick as cream; but "the joints of the fingers were ſwelled and knotty, every knot being a lump of chalk; and I was told," he adds, "that when he played at cards, he uſed frequently to ſcore up the game with his knuckles." (See Medical Communications, vol. i. art. 3.—See alſo Parkinſon's Obſ. on the Nature and Cure of Gout, p. 5.)

Such is the progreſs of gout, as it affects the joints, and while it may, therefore, be called *regular* gout. Sydenham, indeed, and ſome other writers, confine the appellation of *regular* to gout in the feet only; and conſider it as *irregular*, when it attacks the hands or other joints. But Dr. Cullen, Warner, and the phyſicians of the preſent day, in general, agree in calling the diſeaſe, when it conſiſts only of an inflammatory affection of the joints, the regular gout: "and," Dr. Cullen obſerved, "whatever ſymptoms we can perceive to be connected with, or to depend upon, the diſpoſition which produces that inflammatory affection, but without its taking place, or being preſent at the ſame time, we name the *irregular gout.*" Firſt Lines, § 518.

Irregular gout, anomalous, internal or atonic gout, as it has been alſo called, conſiſts of various ſymptoms of diſorder in the internal organs of the body, which do not differ from the ſymptoms affecting the ſame organs under other circumſtances; it is, therefore, ſuſpected that theſe ſymptoms are of gouty origin, when they occur in perſons bearing the marks of a gouty diatheſis or diſpoſition: and eſpecially when, in ſuch habits, either a manifeſt tendency to the inflammatory affection of the joints has formerly appeared, or when the ſymptoms alluded to are intermixed with, and are relieved by, ſome degree of the inflammatory affection. The morbid ſymptoms which appear, in ſuch caſes, and are conſidered as ſigns of *atonic* gout, are principally affections of the ſtomach; ſuch as loſs of appetite, indigeſtion, and its various concomitants of ſickneſs, nauſea, vomiting, flatulency, acid eructations, and pains in the region of the ſtomach. Theſe ſymptoms are frequently accompanied with pains and cramps in the upper extremities of the body, which are relieved by the diſcharge of wind from the ſtomach. Together with theſe affections of the ſtomach, coſtiveneſs alſo commonly occurs; but ſometimes a looſeneſs with colic pains. Theſe affections of the alimentary canal are often attended with all the ſymptoms of hypochondriaſis; as dejection of mind, a conſtant and anxious attention to the ſlighteſt feelings, an imaginary aggravation of theſe, and an apprehenſion of danger from them. In the ſame atonic gout, the viſcera of the thorax are alſo ſometimes affected, and palpitations, faintings, and aſthma occur. And the head alſo is often diſordered, with pains, giddineſs, ſomnolency, and even apoplectic and paralytic affections. (Cullen. See alſo Muſgrave "De Arthritide Anomala," where theſe various modifications of irregular gout are deſcribed at length; and Warner's "Full and Plain Account of the Gout," where his obſervations are tranſlated, pp. 70—90, ſecond edit.)

We may here remark, in paſſing, that many errors have probably been committed, in conſidering almoſt every ſpecies of indiſpoſition, that occurs in gouty habits, as ariſing from the gouty diatheſis. We remember to have heard this point ſtrenuouſly inſiſted upon by the able profeſſor of phyſic, in the univerſity of Edinburgh, Dr. Gregory. Many of the ſymptoms above enumerated are obviouſly connected with the impaired functions of the ſtomach, and occur in dyſpepſia, or indigeſtion, in habits not gouty; ſuch are the various hypochondriac ſenſations; the palpitations of the heart, often ariſing from over-diſtenſion of the ſtomach with flatus, by which the heart is mechanically preſſed upwards: the cramps in different parts of the body, which are often relieved by a diſcharge of wind from the ſtomach; the difficulty of breathing, often occaſioned by great diſtenſion of the ſtomach, which impedes the deſcent of the diaphragm; and the head-ache, giddineſs, &c. which are daily obſerved to be connected with impaired digeſtion. On the other hand, inflammatory diſorders of the lungs and other viſcera, congeſtions in the head, inducing head-ache, ſomnolency, vertigo, &c., and ultimately various degrees of paralytic and apoplectic diſeaſe, not eſſentially different, in any reſpect, from the ſame affections in habits not tainted with gout, have probably been ſuffered to go on, and to prove fatal, under a notion that they were gouty, and the proper remedies have been therefore neglected.

The *irregular* gout occurs in a leſs equivocal form, when the inflammatory ſtate of the joints has come on in the uſual manner, but when, without ariſing to the ordinary degree, or at leaſt without continuing for the uſual time, and receding gradually, as is common, the pain and inflammation ſuddenly and entirely ceaſe, while ſome internal part becomes diſordered. This has been called the *retrocedent* or *repelled gout.* When the gout is thus retrocedent, the ſame internal parts are attacked, and the ſame diſorders produced, as in the irregular or atonic gout, where no previous imperfect attack upon the joints had ſhewn itſelf. The ſtomach is for the moſt part commonly affected, whence violent pain, ſickneſs, vomiting, anxiety, &c.: the heart and lungs are alſo occaſionally attacked; and ſometimes the occurrence of apoplexy, palſy, or delirium, mark the head as the ſeat of the retrocedent diſeaſe.

Another variety of irregular gout has been denominated *miſplaced gout;* namely, when, inſtead of the joints of the extremities, the ſtomach, brain, lungs, inteſtines, kidnies, or bladder, become affected with ſymptoms of inflammation, which give way upon the appearance of the inflammation in the extremities, when that takes place. This inflammation of the internal organs, however, is indicated by the ſame ſymptoms which accompany inflammation of the ſame parts, ariſing under other circumſtances, and in conſtitutions not gouty: and it has probably been ſometimes ſuppoſed to be of gouty origin, when it aroſe from the ordinary cauſes. Dr. Cullen affirms, that he never met with any inſtances of miſplaced gout in his practice, and that no caſe has been diſtinctly made out by medical writers, except that of pulmonary inflammation. But he had known two varieties of internal diſeaſe alternate with external gouty inflammation; *viz.* the one an affection of the neck of the bladder, producing pain, ſtrangury, and catarrhus veſicæ; the other an affection of the rectum, ſometimes marked by pain alone in that part, and ſometimes by hæmorrhoidal ſwellings.

Such are the phenomena, by which the various forms of regular and irregular gout are chiefly characterized. The next object of our inquiry will be the

Cauſes of Gout.—Among the *prediſpoſing* cauſes of gout, an original peculiarity of conſtitution, often tranſmitted from the parent to the offspring, appears to be the moſt common; in other words, the diſeaſe is ſaid to be *hereditary.* This poſition, indeed, has been controverted, eſpecially by Dr. Cadogan (ſee his Diſſ. on the Gout, and all Chronic Diſeaſes, p. 7.); but the diſcuſſion has turned upon a mere diſpute about words. For it is admitted, on all hands, that the *prediſpoſition* of the conſtitution to be affected by gout is tranſmitted from father to ſon, like other peculiarities of habit; like the family-likeneſs, for inſtance, in features, in voice, complexion, &c. It is true, indeed, as Dr. Cadogan contends, that ſome perſons acquire this gouty diſpoſition, who have it not by hereditary tranſmiſſion; and, on the other hand, that the hereditary prediſpoſition may be counteracted by various cauſes, but particularly by certain modes of life, ſo that the diſeaſe itſelf ſhall never appear. Yet it is equally true, that the ſame occaſional cauſes, which will excite the diſeaſe in thoſe who are hereditarily prediſpoſed to it, will not produce it in others, although applied in greater force; and, therefore, the exiſtence of an original conſtitutional prediſpoſition muſt neceſſarily be inferred. The middle and advanced periods of life are alſo more diſpoſed to gout, than the early periods: thus it does not commonly attack men until after the age of thirty-five, and generally not till a ſtill later period. When the gout does appear, in more early life, of which there are inſtances, it ſeems to be in thoſe in whom the hereditary diſpoſition is very ſtrong, and to whom the exciting cauſes have been applied in a conſiderable degree. Hippocrates remarks, that eunuchs are not liable to be affected by gout, nor boys previous to venery: but the intimation included in the remark is probably unfounded; ſince, with reſpect to the latter, the diſeaſe, as we have already ſtated, is almoſt peculiar to an advanced period of life; and the eunuchs, who, in the time of Hippocrates, were chiefly Perſian ſlaves, were doubtleſs confined to the ſtrict diſcipline and the frugal and temperate life, which the rigorous laws enjoined to all, and therefore not expoſed to the moſt active cauſes of gout. For Galen, in his commentary upon this obſervation of Hippocrates, obſerves that, in his time, the remark was no longer true, "owing to too much indulgence on their part in an indolent, as well as intemperate mode of life:" and the remark is confirmed by modern experience. (Van Swieten, loc. cit.)

It has been fully aſcertained, indeed, that the principal ſource of the gouty habit conſiſts of high feeding and indolence conjoined. Sydenham (who, upon the ſubject of gout, ſtands unrivalled in accuracy of obſervation, and the model of all ſucceeding writers, many of whom have done little more than copy his hiſtory of it) begins his account of the diſeaſe with theſe remarks. "The gout generally attacks thoſe elderly perſons who have ſpent the greater part of their lives in eaſe and indulgence, both in the uſe of high feeding and of wine, or other ſpirituous and fermented liquors; and who, in conſequence of the ſluggiſhneſs of advanced life, have ceaſed from all thoſe exerciſes to which they were accuſtomed in their youth. The gout, however," he adds, "does not always wait till an advanced age; it ſometimes attacks thoſe who are in the prime of life. But theſe perſons have unfortunately received the ſeeds of the diſeaſe from their parents; or, if not, they have indulged in premature and exceſſive venery, or left off entirely thoſe exerciſes which they had previouſly uſed with great activity, and have been beſides moſt indulgent to the appetite, and drank to exceſs of vinous and ſpirituous liquors, afterwards ſuddenly turning to thoſe that are thin and cold." (Sydenham, Tractatus de Podagra.) Theſe facts have been long known. There is a Greek epigram literally ſignifying, "of limb-relaxing Bacchus and limb-relaxing Venus is born a daughter, the limb-relaxing Gout." And a ſimilar obſervation is contained in the adage, "Bacchus pater, Venus mater, et Ira obſtetrix Arthritidis." While this fact is confirmed, on the one hand, by the teſtimony of ages in the affirmative, it is corroborated alſo, on the other hand, by obſervation in the negative. Dr. Cullen remarks that gout ſeldom attacks thoſe who are employed in bodily labour, or who live much upon vegetable aliment, or thoſe who make no uſe of wine or other fermented liquors. Indeed, the gout is ſaid to be altogether unknown where theſe liquors are not uſed, as among the common people of Turkey. Among the lower orders of people, even in this country, the diſeaſe is very rare, and ſtill more rare in Scotland and Ireland, where animal food and ſtrong ale and beer are leſs uſed. Van Swieten obſerves, that ſome people who, from comfortable circumſtances, have been reduced to labour for their ſuſtenance, and to exchange a luxurious table and indolence for a ſpare diet and activity, have loſt their gout. He mentions particularly the inſtance of a certain prieſt, who enjoyed a rich living, and had been an old and conſtant ſufferer from the gout; but happening to be taken by the pirates of Barbary, he was kept conſtantly at work in the galleys for the ſpace of two years: "which had this good effect, that afterwards, when he was ranſomed from captivity, having loſt all his troubleſome and monſtrous fatneſs, he never once had a fit, though he lived ſeveral years after the event." (Van Swieten, Comment. ad Aph. 1255.) Several anecdotes of a ſimilar nature are related by the induſtrious Schenckius. (Obſ. Med. Rarior. lib. v. p. 657. edit. 1644.) In a word, much exerciſe, which will often counteract the influence of intemperance, will, when combined with temperance, counteract even the hereditary diſpoſition to the diſeaſe.

The effect of full living and indolence, in producing the gouty diatheſis, is alſo manifeſt from the form and temperament of the perſons in whom it occurs. Theſe are eſpecially men of robuſt and large bodies with large heads, and of full and corpulent habits. They have commonly alſo a coarſer ſkin; and if, with the ancients, we might denote the temperaments of men by certain terms, we ſhould ſay that the gout eſpecially aſſails men of a *cholerico-ſanguine* temperament, and ſeldom attacks the purely ſanguine or melancholic. Women are not very liable to the gout, probably from their leſs intemperate mode of life, in general, than that of men: but thoſe females whom it attacks are generally of robuſt and full habits. It is ſaid not to occur in them commonly till after the ceſſation of menſtruation; which perhaps only implies that it is a diſeaſe of advanced life. For as Dr. Cullen juſtly remarks, "it often happens to ſuch (the robuſt) long before the menſtrual evacuation has ceaſed," and he had "found it occurring in ſeveral females, whoſe menſtrual evacuations were more abundant than uſual." (Firſt Lines, § 494.) A fact, which we may explain, with Dr. Gregory, by obſerving, that thoſe women who indulge much in vinous and fermented liquors, are more liable to menorrhagia than others.

It is obvious, then, that the experience of all ages concurs in aſſigning intemperance and indolence as the principal ſources of that habit of body, in which the gout is liable to occur. This habit, or prediſpoſition, ſeems to be ſufficient, in many caſes, to produce the diſeaſe itſelf, or at leaſt to require the application of ſlight and imperceptible exciting cauſes to bring it forth. The diſeaſe, indeed, depends ſo much upon prediſpoſition, that it is difficult to aſſign the occaſional cauſes; the ſame agents appear to be ſometimes the generators of a prediſpoſition to it only, and at other times actually to excite the diſeaſe.

The exciting cauſes which often ſuddenly bring on a fit of the gout, in thoſe who are prediſpoſed to it, are, in the firſt place, thoſe circumſtances which induce a ſudden debility, eſpecially of the ſtomach. The concurrence of *indigeſtion,* and the local inflammation in gout, is one of the characteriſtics of the diſeaſe; and, as we have already ſtated, the latter is uſually preceded for ſome time by the former. Hence whatever ſuddenly depreſſes the digeſtive power, is liable to induce the local and conſtitutional diſeaſe. Thus a paroxyſm of gout has frequently been excited by an occaſional exceſs in the uſe of wine or ſpirits; by overloading the ſtomach with food, or by eating ſuch as is not eaſily digeſtible in its nature; by the copious uſe of vegetable acids or aceſcent matter, eſpecially by weak aceſcent wines, punch, &c.; all of which tend to debilitate the digeſtive organs either directly or indirectly. In the ſame way, exceſs of venery, which powerfully influences the ſtomach, (Van Swieten, Aph. 586, and 1255,) has often brought on a fit. This ſeems to have been univerſally underſtood by the ancients. We have already noticed the obſervation of Hippocrates; and Aëtius, in recounting the general cauſes of gout, ſays, theſe are, "abounding crudities, frequent drunkenneſs, and, above all, an immoderate uſe of venery." (Sermon xii. Cap. 6.) Sydenham and Van Swieten add their teſtimony to the fact. Intenſe ſtudy, night-watching, exceſſive anxiety and attention to buſineſs, all of which greatly depreſs the power of the body in general, and of the ſtomach in particular, deſtroying the appetite, and producing a ſenſe of uneaſineſs, ſinking, or weight about the region of the ſtomach, are likewiſe enumerated among the occaſional cauſes of the gouty paroxyſm. The ſame is true with reſpect to the violent emotions and paſſions of the mind, more particularly of anger. "Ira obſtetrix arthritidis" is part of the adage above quoted: and the three cauſes of gout, inſiſted on by Dr. Cadogan, are intemperance, indolence, and *vexation.* The influence of violent mental emotions on the functions of the body is, indeed, very manifeſt, and more eſpecially on the function of digeſtion; the diſturbance of which, we have already obſerved, is exceedingly inſtrumental in the production of gout. "The firſt immediate effect of violent grief or vexation," ſays Dr Cadogan, "is to take off the action of the ſtomach entirely. Let us ſuppoſe a man in the beſt health, the higheſt good humour and ſpirits, as well as good ſtomach, ſitting down to dinner with his friends, receives ſuddenly ſome very afflicting news. Inſtantly his appetite is gone, and he can neither eat nor ſwallow a morſel. Let the ſame thing happen after he has made a hearty cheerful meal, as ſuddenly the action of his ſtomach, the whole power of digeſtion is cut off totally, as if it were become paralytic, and what he has eaten lies a moſt oppreſſive load. Perhaps as the exceſs of weakneſs is often convulſion, it may be rejected by a violent vomit, or do greater miſchief: for which reaſon ſuch ſtrokes of diſtreſs are leſs hurtful received upon an empty than a full ſtomach." &c. (Loc. cit. p. 55.) The gouty habit, indeed, is often an irritable habit; and Sydenham obſerves, that a fit of gout may be called a fit of anger." (See alſo Van Swieten, § 1258.)

Among other exciting cauſes of gout, the ſudden ceaſing from the cuſtomary exerciſes or labour is commonly mentioned, and its principal effect is probably upon the function of digeſtion, which is ſo much under the influence of exerciſe. Indolence, in general, as contributing to induce the gouty diſpoſition, is well underſtood; and the ſudden ceſſation of activity, like all other ſudden changes, is apt to produce a ſudden acceſſion of the paroxyſm, in thoſe who are pre-diſpoſed to the diſeaſe. In a ſimilar manner, a ſudden change in the mode of living, the oppoſite to exceſs, namely, from high feeding to a very ſpare and abſtemious diet, is liable to induce the paroxyſm of gout. That ſuch a ſudden abſtraction of the powerful ſtimulus of a copious ſupply of food and ſtrong liquors, muſt neceſſarily induce a conſiderable direct debility in the organs of digeſtion, is well underſtood by thoſe who are acquainted with the laws of ſtimulants on the animal body. (See DEBILITY and EXCITABILITY.) This fact, however, although ſometimes adduced as an argument againſt the advantages of an abſtemious regimen, in preventing the gout, affords no ſuch legitimate inference. It is too obvious, indeed, to require an elaborate diſcuſſion, that all extremes, haſtily adopted, are liable to derange the animal economy; and that habit alone can render extreme moderation invariably beneficial, on the one hand, and enable us to bear exceſs with a conſiderable degree of impunity on the other. Another mode of debilitating the ſyſtem, which ſometimes brings the paroxyſm of gout, is exceſſive evacuation of any kind; ſuch as by hæmorrhage, briſk purging, vomiting, &c.; eſpecially in aged perſons, whoſe conſtitutions are already much broken down by the diſeaſe.

Sudden viciſſitudes of weather, eſpecially when connected with moiſture, as from mild to cold, or from ſevere cold to damp and mild weather, often excite the gout; hence, Sydenham remarked, that the moſt frequent occurrence of the gouty paroxyſm takes place in the latter end of January, or the beginning of February. The fit may be produced either by the local application of cold and moiſture to the feet, or by a general expoſure to it; for ſuch expoſure, which in moſt people will occaſion rheumatiſm, a catarrh, or a ſore throat, will, in a gouty ſubject, excite a fit of the gout. In like manner, bruiſes or ſprains of the leg or foot, or mere over-exerciſe of the muſcles and ligaments of thoſe parts, as in long walking, will ſometimes bring on a paroxyſm.

There is another alleged cauſe of the gout, which it would not now be neceſſary to mention, were it not noticed by Boerhaave, Van Swieten, and others, *viz. contagion.* Van Swieten conſiders the diſeaſe as analogous to dyſentery and other maladies, which, although originating from very obvious cauſes, neverthelеſs propagate themſelves afterwards by contagion. But the ſtories, by which this doctrine is ſupported, are ſomewhat ridiculous; ſuch as this, that a dog lying at his maſter's feet during a paroxyſm of the gout, ſuddenly ran howling and barking round the room, expreſſing the pain which he had caught from his maſter, whoſe torture at the ſame time became greatly alleviated, &c. (Swieten Com. ad § 1255.)

Of the Diagnoſis.—The attack of the *regular* gout is readily diſtinguiſhable from the only diſeaſe which reſembles it, *viz.* acute rheumatiſm, if all the ſymptoms are taken into conſideration. In the firſt place, gout is commonly a diſeaſe of advanced life; acute rheumatiſm is moſt frequent from the age of 18 to 30. Nor does rheumatiſm, like the gout, ſeize the feet in preference to the other joints, or remain for a conſiderable time in the ſame joint; but at the firſt attack it often attacks every joint of the body in ſucceſſion, and ſometimes continues for ſeveral months. The colour of the ſkin of the part affected in rheumatiſm, if it be changed, is only ſlightly red, whereas it becomes of a deep bright red in the gout. The pain in the rheumatiſm is not extremely acute, while the part is at reſt, but becomes violent when it is moved only; which is not the caſe in the gout. And the ſymptoms of indigeſtion and diſordered ſtomach, which precede the paroxyſm of the gout, together with the marks of diſtinction juſt mentioned, will ſerve particularly to determine the nature of the paroxyſm. It muſt be admitted, however, there are inſtances of the combination of the ſymptoms of the two diſeaſes, which renders it difficult to decide to which of them the individual examples belong. (Heberden, Comment. de Morb. p. 58.)

Again, the ſymptoms which the *irregular* gout preſents, are extremely numerous and proteiform, appearing frequently as dyſpepſia, hyſteria, hypochondriaſis, aſthma, palpitation, ſyncope, vertigo, apoplexy, paralyſis, &c. according to the original or acquired tendency of the conſtitution to thoſe diſeaſes. Hence the diſcrimination between theſe modifications of gout, and the diſeaſe which it mimics, is occaſionally very difficult.

Of the nature or proximate cauſe of Gout.—This is a part of the ſubject upon which, if we were to confine ourſelves to the communication of actual and uſeful knowledge, we ſhould be altogether ſilent, or ſay but a few words. The obſervation, indeed, will apply to many other diſeaſes, as well as to gout; but as gout is an affection almoſt excluſively occurring in the higher claſſes of ſociety, among the wealthy and intelligent, it has claimed a more general attention, and become the object of more general diſcuſſion. It is greatly to be lamented, however, that the moſt miſtaken notions have prevailed, from the earlieſt times, in regard to the nature and extent of the inſight, which we are capable of obtaining, into the operations of the animal economy, and to the means by which we can obtain it. Inſtead of confining themſelves to the obſervation of the phenomena of health and diſeaſe, faithfully recording theſe phenomena, and arranging them according to their moſt obvious analogies, phyſicians have been buſy in ſearching after their hidden cauſes; and, fancying a reſemblance between the moſt diſſimilar things, have ſucceſſively called to aid the analogies of every human ſcience, as it advanced in cultivation, to explain the phenomena of animal life. The ancient doctrines of numbers and elements, and their qualities, and the modern diſcoveries and ſuppoſitions of the chemical, mathematical, and mechanical philoſophers, have in turn been aſſumed as affording the moſt perfect elucidation of the operations of the living body; and, as they have, of courſe, been in turn exploded, we need not recur to any other argument in proof of their want of foundation. By theſe remarks we wiſh only to ſhew the futility of reaſoning on the ſubject of proximate cauſes of diſeaſe, which, as we are and muſt remain entirely ignorant of the proximate cauſe of health and life, muſt be equally inſcrutable. "Nam quæ demum cauſæ," as Celſus juſtly obſerves, "vel ſecundam valetudinem præſtent, vel morbos excitent, &c. ne ſapientiæ quidem profeſſores ſcientia comprehendunt, ſed conjecturâ proſequuntur.' (De Med. Præf. lib. i.) The inquiry reſpecting the proximate cauſe of diſeaſes is as futile as the ſpeculations of the Carteſians to explain the eſſence of gravitation, and have as little to do with the advancement of true medical ſcience, as the hypotheſis of an ether aſſiſted Newton in his obſervations and calculations reſpecting the phenomena of that agent.

If theſe obſervations ſhould not be ſufficiently intelligible to the general reader, a brief enumeration of the hypotheſes, which have been invented by medical writers, in order to explain the eſſential nature of gout, will probably be ſufficient to prove the abſurdity of ſuch attempts. Moſt of the Greek and Roman phyſicians, with the exception of the methodiſts, conſidered the preſence of a corrupted humour in the ſmall veſſels as the eſſential cauſe of gout. Hippocrates believed this humour to conſiſt of bile and phlegm, which flowed upon the joints. Galen followed him in ſuppoſing the defluxion upon the joints to be chiefly pituitous or phlegm, or bile mixed with phlegm. Paulus Ægineta attributed the diſeaſe to a redundancy of blood, black bile, and phlegm. Trallian and Caſſius imagined, that it aroſe from the blood itſelf being forced into the joints; and Oribaſius affirmed that the blood in gouty people was viſcid, reſembling melted glaſs, which remaining in the joints, produced the cretaceous matter. Aretæus, one of the moſt able of the Greek writers, is the only one who paſſes over the eſſential cauſe of the diſeaſe, a knowledge of which he aſſigns to the gods alone; the evident cauſes, he ſays, are apparent to man. Themiſon, Cælius Aurelianus, and the methodic ſect, attributed gout to relaxation or ſtricture of the parts; ſome, however, imputed it to the one ſtate, and others to the oppoſite. The Arabians followed cloſely in the path of their maſters, and taught that one or other of the humours was predominant, or that they were variouſly combined, in caſes of gout. So luminous and inſtructive were the doctrines of the ancients!

In the dawn of modern ſcience, the humours were almoſt baniſhed by the hypotheſes of the chemiſts; but although we hear little more of bile, phlegm, and melancholy, or black bile, all diſeaſe was nevertheleſs attributed to a morbific or peccant matter, and ſalts, earth, or tartar, were deemed the immediate cauſe of gout and other maladies; and Paracelſus, Van Helmont, and others, are very abuſive of the ancients for promulgating ſo many abſurd doctrines! When the mathematical and mechanical phyſicians aroſe, they took up the hypothetical doctrines of their predeceſſors, and reaſoned concerning the action of theſe ſuppoſititious humours, ſalts, &c. upon mechanical principles; the chemical doctrines predominated, however, over the ancient humours. Thus, to uſe the words of Dr. Warner, "according to Sydenham the arthritic matter conſiſts of the putrefying heat and acrimony of indigeſted juices: Boerhaave gives it the appellation of an acrimony or over-toughneſs of the liquid which waters the nervous parts: Liſter makes it to be a crude and viſcid ſerum become ichorous and corroſive: Bennet defines it an acrimony that is invariably of the putrid, volatile alkaline nature: Quincy ſays that it conſiſts of rigid particles, ſuch as approach near to the ſaline, of the nature of tartar, and not much unlike that which forms itſelf into concretions in the urinary paſſages: Cheyne in one place calls it tartarous, urinous, or other ſalts: Ingram will have it to be a coagulation made by a mixture of ſaline particles with the oil of the adipoſe membrane. As every one of theſe writers makes the gouty matter to be an acrimony taken in with our aliment, which they call either putrid, viſcid, corroſive, ſaline, urinous, or tartarous, ſo Dr. James, whoſe name needs no addition, diſagreeing with them all, hath judged this acrimony to be earthy." (See Warner on the Gout, p. 91.—See alſo a ſenſible and learned diſquiſition on this topic, in "An Hiſtorical, Critical, and Practical Treatiſe of the Gout, by Thomas Thomſon, M.D. Lond. 1742.) But ſuch hypotheſes did not die with Dr. James; for in a treatiſe on the gout, publiſhed in 1805, we find the following ſtatement: "The proximate cauſe of gout appears to be, a peculiar ſaline acrimony exiſting in the blood, in ſuch a proportion, as to irritate and excite to morbid action, the minute terminations of the arteries, in certain parts of the body:" (See Obſervations on the Nature and Cure of Gout, &c. by James Parkinſon,) a ſtatement, which is equally indefinite, hypothetical, and practically uſeleſs, with thoſe that have preceded it.

On reviewing theſe opinions of men, who have been deſervedly eſteemed the ornament of their profeſſion, ſome readers may expreſs their ſurpriſe that ſuch an extraordinary difference ſhould be found among them, and that ſo much error (for of oppoſite opinions one half at leaſt muſt be wrong) ſhould exiſt in the ſcience. But the only rational ground for wonder is, that ſo many men of ſound underſtanding ſhould have employed themſelves in inquiries beyond the reach of their faculties, and ſhould have imagined that, in framing hypothetical ſuppoſitions, they had acquired any actual knowledge, or had advanced one ſtep in the practical improvement of their art. If a number of philoſophers were engaged in inveſtigating the nature of light and heat, and ſhould not only execute a ſeries of experiments on the reflection, refraction, and diviſibility of the one, and on the properties of expanſion, inflammation, vaporization, &c. of bodies, which belong to the other; but ſhould likewiſe think it neceſſary to form conjectures relative to the nature and qualities of the ſun, which is the ſource or proximate cauſe of both; theſe conjectures, like the medical hypotheſes juſt quoted, however they might amuſe us, would add not a tittle to our knowledge, nor would the want of them be any diminution of our information, or of our practical powers.

The great ſource of theſe hypotheſes, reſpecting the exiſtence of a morbid humour in the gouty habit, is, no doubt, the appearance of a palpable matter, of a peculiar nature, in the joints diſeaſed. This chalk-like matter, however, will be found to afford no ground for ſuch a concluſion, if the circumſtances are duly examined. In the firſt place, the production of this morbid matter may be the *effect* of the diſeaſe; and that it is ſo, is apparent from its not occurring in all caſes of gout, and from its ſeldom or never accompanying the firſt attacks of the diſeaſe, but only appearing after repeated paroxyſms. Nor have we any direct evidence, from experiment or obſervation, of the ſmalleſt difference in the blood or other humours of gouty people, from thoſe of other perſons. On the other hand, we know that the veſſels in particular parts acquire the power of ſecreting or otherwiſe producing new fluids, when inflammation is induced. Thus a blow in a fleſhy or membranous part ſhall occaſion inflammation, and a conſiderable quantity of *pus* ſhall afterwards be accumulated or diſcharged, as in a common abſceſs: yet no one ſuppoſes that this *pus* was contained in the maſs of the circulating blood, any more than he ſuppoſes that urine and bile are contained in that maſs, and not elaborated by the kidnies and liver. The appearance of the chalky matter, or urate of ſoda, in the parts attacked by gouty inflammation, is therefore to be conſidered as the reſult of that inflammation, and not as its cauſe. If the general maſs of blood were contaminated with this morbid matter, or any peculiar acrimony tending to produce it, why is it never depoſited on the viſcera and other internal parts? yet no ſuch depoſition was ever obſerved: thoſe parts remain invariably free from it in the moſt inveterate forms of the gout, and the appearance of chalk-ſtones is confined excluſively to the membranous and ligamentous parts which exhibit inflammation externally. In the next place, the frequent and ſudden tranſlation of the diſeaſe from one part to another is not conſiſtent with the ſuppoſition of its dependance on the preſence of a morbid matter: but analogous changes or *metaſtaſes* of other inflammations, in which no peculiar matter is produced, are exceedingly common. Beſides, upon the ſuppoſition of ſuch a tranſlation of morbid matter, its operation ſhould be ſimilar on every part: whereas it ſeems to be very different, being ſtimulant and exciting inflammation in the joints, but ſedative and deſtroying the tone or energy of the ſtomach. Farther, as Dr. Cullen juſtly obſerves, "the ſuppoſition of a morbific matter is quite ſuperfluous; for it explains nothing, without ſuppoſing that matter to produce a change in the ſtate of the moving powers; and a change in the ſtate of the moving powers, produced by other cauſes, explains every circumſtance, without the ſuppoſition of a morbific matter: and to this purpoſe it may be obſerved, that many of the cauſes exciting gout do not operate upon the ſtate of the fluids, but directly and ſolely upon that of the moving powers." Dr. Cullen likewiſe remarks, that the ſuppoſition of a morbific humour being the cauſe of gout has been hitherto uſeleſs, ſince it has not ſuggeſted any ſucceſsful method of cure: but, on the contrary, that particular ſuppoſitions have often corrupted the practice, and have frequently led from thoſe views, which might be uſeful, and from that practice which experience had approved. (Firſt Lines, pt. 530.)

Having failed to explain the phenomena of the diſeaſe, on the ſuppoſition of a morbid condition of the fluids of the body; we might take up the doctrine of the *nervous* pathologiſts, and attempt an explanation of the ſymptoms, upon the notion of a derangement of the living ſolid, or moving fibre, as Dr. Cullen has done. (Loc. cit. §. 533—6.) But it is ſufficient to peruſe the account given by that celebrated phyſician, to be convinced that it is a mere repetition of the phenomena of the different varieties of the diſeaſe, couched in a new phraſeology; and therefore that it is practically as uſeleſs as that which he controverts. It cannot be queſtioned, we apprehend, in the preſent ſtate of our phyſiological knowledge, that the prime agents in the operations of the living body, whether in health or diſeaſe, are the ſolid, irritable, and moving parts; and that by theſe the fluids or humours are chiefly elaborated and modified: but it is likewiſe obvious, that the ſolids derive their powers from certain conditions of the circulating fluids, which are varied by reſpiration, nutrition, &c. Therefore the diſputes between thoſe, who confine the origin of gout to the one or other part of the ſyſtem excluſively, muſt be deemed frivolous. Our knowledge is neceſſarily limited to the phenomena of the diſeaſe, and the order in which they occur, and to the effects of phyſical agents upon them, as taught us by obſervation and experiment. "Nulla tamen adhuc obſcurior quæſtio eſt," ſays Dr. Heberden, "quam quæ verſatur de hujus morbi cauſis, effectibuſque, et remediis." (Comment. de Morb. Cap. 9.) But we cannot doubt that theſe numerous hypotheſes, which have at once diverted the minds of phyſicians from the labour of obſervation, and have perverted their views of facts, have rendered the ſubject more obſcure than it would otherwiſe probably have been.

Before we come to the method of treatment, there is another queſtion to be noticed, upon which much diſcuſſion has taken place, and which has perhaps been popularly ſolved with conſiderable incorrectneſs: we mean the queſtion, whether regular fits of the gout are ſalutary; *i. e.* whether they altogether remove or prevent other complaints. The affirmative is generally maintained: and this opinion has ariſen partly from obſervation, and partly from the hypotheſis, that a paroxyſm of gout conſiſts in an effort of the conſtitution, by which the morbific matter is thrown off through the part affected. In a number of inſtances, beyond a doubt, the various ſymptoms of indigeſtion, whether affecting the ſtomach and bowels only, or the lungs and heart by vicinity, and the head by ſympathy, are relieved or altogether carried off by the complete fit. Perhaps Dr. Heberden is ſcarcely correct, when he conſiders this relief as either, in a great meaſure imaginary, like that which many invalids invariably obtain from a change of their phyſician, or from a new medicine; or as not more frequent than ſimilar relief from ſlight indiſpoſition after other violent diſeaſes: he appeals, however, to an ample experience in ſupport of his opinion. He thus writes: (we tranſlate from the Latin edition) "There are ſome countries in which the itch is a very frequent diſeaſe, and there this eruption is deemed ſalutary. Even an ague was formerly conſidered by the majority of phyſicians as a wholeſome affection, and is ſtill ſo conſidered by ſome perſons: its occurrence was therefore a ſubject of congratulation both with the patients and their friends, and every precaution was taken not to get rid of it too ſoon. But theſe notions are almoſt exploded in this country; and if we ſhall diſcover a remedy equally effectual for the gout, as thoſe with which we cure the diſeaſes juſt mentioned, we ſhall at length learn with what perfect ſafety and advantage the gout may likewiſe be eradicated."—"I confeſs," he adds, "that I have ſeen ſome perſons who rejoiced on the firſt attack of the gout, as if it aſſured to them all future happineſs, and who, dreaming only of the moſt perfect health to come, eaſily perſuaded themſelves that this firſt fit had been wonderfully beneficial This is a common diſpoſition with mankind, as often as they have recourſe to new phyſicians, or to remedies not before tried. But, paſſing by ſuch perſons, let us inquire the opinion of thoſe, who have ſuffered under long and frequent paroxyſms, and who are better acquainted with the diſeaſe. Of a very great number of patients whom I have ſeen, and whoſe caſes I have committed to writing, more than twice as many, to ſay the leaſt, have found no relief whatever from their previous complaints, in conſequence of the regular fit, or have even ſuffered an increaſe of them, as have ſeemed to derive any benefit: and, in my opinion, the evils which were attributed to the diſeaſe, more certainly originated from that ſource, than the ſuppoſed advantages. Occaſionally, indeed, we find that other complaints have ceaſed on the ſupervention of the gout; but the ſame thing alſo happens after acute fevers, after palſy, aſthma, ſmall-pox, and inſanity, of all which I have witneſſed many examples; yet no one will call theſe diſeaſes ſalutary. On the other hand, gout frequently occurs to perſons affected with vertigo, aſthma, indigeſtion, and melancholy; where, ſo far from alleviating theſe diſorders, it produces a conſiderable aggravation of their ſymptoms. Beſides, in ſome patients, all theſe complaints conſtantly accompany the paroxyſm of gout, and continue during the whole of its courſe." (Loc. cit. p. 36.)

At all events, if we look at the life of the gouty in general, we find ultimately but little ground for congratulation. In ſome, it is true, the diſeaſe occurs at diſtant intervals, and ſoon goes off, and therefore occaſions very little, if any, obvious injury. Even epilepſy itſelf, when its attacks are rare, does not prevent the patient from reaching old age. But this is far from being the caſe frequently with either diſeaſe. In many perſons whom the gout attacks, the health ſuffers from the time of the firſt fit, and gradually grows worſe, until it is greatly broken, or fails altogether. It may poſſibly be doubted, in ſuch caſes, whether the gout cauſed theſe evils; but we are very certain that it has not been the remedy for them, nor in any way ſalutary.

We may juſtly wonder, therefore, with Dr. Heberden, how it has come to paſs, that the gout is held in ſo much honour in England; unleſs it be that it is a diſeaſe, which ſeveral great men have ſuffered, and which chiefly attacks thoſe happy perſonages who enjoy leiſure and affluence, and all the good things of life. Louis XIV. of France happened to labour under a fiſtula in the anus, and the ſurgeons of that time were conſtantly called in by his faſhionable ſubjects to adminiſter relief to imaginary fiſtulæ; which royal diſeaſe they perſuaded themſelves had attacked them; and it is probable, as Dr. Heberden ſuggeſts, that had there exiſted any medicated waters in France, capable of producing fiſtula, they would have been viſited with the ſame anxiety with which our countrymen haſten to thoſe of Bath, in the hope of returning with the gout.

Of the Cure.—Perhaps this may be deemed an improper term for the treatment of a diſeaſe, which, on the one hand, has been affirmed to be incurable by medicine, and called the opprobrium of phyſicians; and, on the other, has been conſidered ſo ſalutary, that it ought not to be cured, and could not be cured without the moſt imminent danger to the patient. Nay, farther, as much trouble has been taken to produce and excite the gout, as to relieve or cure it; and all the evils which arthritics ſuffer, are not ſuppoſed to ariſe from a ſuperabundance of gout, but becauſe they have not had enough. It would be only juſtice, however, as the intelligent writer juſt quoted remarks, to the art of phyſic, no longer to call the diſeaſe its opprobrium, until the patients lay aſide their prejudices and fears, and have a diſpoſition to be cured. "Utinam," he adds, "tam in promptu eſſet invenire, quam tutum adhibere, podagræ remedium." (Comment. p. 43.)

The treatment, it is obvious, muſt be neceſſarily very different according to the different forms of the diſeaſe, the different periods of life, and the ſtate of ſtrength of the patient, &c. We ſhall firſt ſpeak of the practice neceſſary to be purſued in the regular gout; which will reſolve itſelf into the treatment requiſite during the fit, and that which is proper during the interval.

Treatment of the Regular Fit.—All active meaſures, during the occurrence of a regular paroxyſm of gout, have been preſcribed by writers in general ſince the days of Sydenham. This phyſician remarked, that the more violent the pain and inflammation, the ſhorter in general will be the fit, the recovery moſt perfect, and the interval between this and the ſucceeding paroxyſm the longer. If this opinion were admitted as juſt, it would ſuggeſt the prohibition of any remedies which might moderate the inflammation. But againſt this doctrine another hypotheſis has been advanced by Dr. Cullen, which is at leaſt equally plauſible, and better ſupported by analogy, if not by fact: namely, that the violence of the inflammation may weaken the tone of the parts, and while it renders them leſs liable to ſimilar violent attacks, and the conſequent more perfect recovery, may, by that very debility, invite a return of the diſeaſe. On the whole, the indications of practice generally purſued at preſent, are to moderate the violence of the inflammation and febrile action, when it is ſevere, without applying any active remedies to the foot itſelf. After enumerating the various external applications, ſuch as poultices, fomentations, bliſters, ſinapiſms, camphor, and ſtimulating ſubſtances, which have been occaſionally recommended, Dr. Cullen concludes, that from any of them there is danger of rendering the gout retrocedent; "and that therefore the common practice of committing the perſon to patience and flannel alone, is eſtabliſhed upon the beſt foundation." As there is no danger from the fit of gout, when regular, in a conſtitution not much broken, this method may be purſued with a certain degree of impunity: but it cannot be queſtioned, that the loads of *flannel*, which are ſometimes uſed, often augment the neceſſity for a ſupply of *patience*, by increaſing the inflammation and pain in the foot. It is true, that the parts thus ſwelled and painful, are more acutely ſenſible to cold, as well as to other impreſſions, than in health; but no covering beyond what is ſufficient to prevent a troubleſome ſenſation of cold, if that ſhould occur, can be neceſſary. (Heberden.) All poultices, fomentations, and warm bathing during the inflammatory ſtage are pernicious.

It is more than probable, that conſiderable errors have been committed, upon the hypothetical notion of keeping the gout in the extremities, at leaſt in the younger ſubjects of gout, by deviations from the antiphlogiſtic regimen. In ſuch ſubjects vinous and fermented liquors ſhould be altogether abſtained from during the fit; and the diet ſhould conſiſt of light aqueous and vegetable matters, or thin animal broths: the bowels ſhould be kept open by laxative medicines, and the ſkin moiſt by diaphoretics of the neutral ſalts. This is at leaſt a palliative ſyſtem, and the prejudices of men in general are averſe to any more active interference with the diſeaſe. But in caſe the inflammation is extremely violent, in young and hale men, Sydenham, Cullen, Huxham, and other able authorities, concur in recommending the employment of blood-letting from the arm. This, however, they do not recommend to be often repeated, on account of the debility which may enſue; and as the part affected is not an organ important to life, and the inflammation ſo purely local, there does not appear to be any good reaſon for recurring to this remedy, except in caſes of extraordinary violence, in very plethoric habits, in which the ſymptomatic fever itſelf might prove hurtful. Local blood-letting, by means of leeches applied to the foot itſelf, promiſes more advantage, and experience itſelf has proved the efficacy and ſafety of the practice. (See Cullen, Firſt Lines, par. 563.—Muſgrave de Arthrit. regulari, cap. 8. § 4.) Cupping and ſcarifying the neighbouring parts have alſo been found beneficial.—(Muſgrave.)

We are perſuaded that hypotheſis has had much more influence than obſervation and experience, in exciting the general fears about interfering with the progreſs of the gouty inflammation, and of the danger of its being driven to ſome internal part by ſuch interference. When it was believed, that a quantity of morbific matter exiſted in the inflamed part, it was inferred, of courſe, that it could only be removed by expulſion or by repulſion, in which laſt caſe it muſt fall upon ſome other organ. We know very well, that the ſame hypotheſis, and the ſame fears prevailed no long time ago with reſpect to cooling the ſkin in fevers, and eſpecially in eruptive fevers, ſuch as ſcarlet fever and ſmall-pox. "The perſpiration will be checked," ſaid the theoriſt, "if you allow the ſkin to be cooled, and the *peccant matter* muſt therefore be thrown back upon the bowels, or the lungs, or the brain, and the effect may be fatal." But ample, and unvarying experience has now demonſtrated, not only that ſuch danger was altogether imaginary, but that waſhing the ſkin with cold water, even under the full eruption of ſcarlatina, and in the eruptive fever of ſmall-pox, affords the moſt grateful relief to the patient, and is the moſt effectual moderator of his diſeaſe. (See Cold, *effects of as a remedy.*) Nor is a conſiderable experience of the ſafety and efficacy of a ſimilar practice, in ſubduing the inflammation of gout, wanting. The great Dr. Harvey himſelf, whoſe name is immortalized by the diſcovery of the circulation of the blood, was in the habit of immerſing his foot in cold water, as ſoon as he perceived the approach of the gout, and thus removed the diſorder: he lived to the age of eighty. Van Swieten mentions an officer of infantry, who was induced to rub his gouty feet with ſnow, and afterwards, emboldened by ſucceſs, walked a little way barefoot upon the ſnow, and returned quite free from pain: the interval before another fit was alſo lengthened by this practice. Similar obſervations were likewiſe made by the ancients. Aetius informs us, that he had ſeen a perſon labouring under what he calls a bilious gout, "who obtained extraordinary relief from immerſing and keeping his feet ſome time in cold water." And it is an aphoriſm of Hippocrates, that "cold water, copiouſly poured upon ſwellings of the joints, painful ulcers, *gouty diſorders*, and convulſed limbs, leſſens and removes the pain." (Aph. 25. ſec. 5.—See alſo Heberden Comment. p. 45.—Van Swieten, Com. ad Aph. 1273.) But the moſt extenſive evidence of the efficacy of this practice, in *curing* the paroxyſm of gout, has been adduced by Dr. Kinglake, (ſee a Diſſertation on Gout, &c. Lond. 1804,) who brought forward about thirty caſes, in which the application of cold water to the inflamed part, during the gouty paroxyſm, was invariably and ſpeedily ſucceſsful in relieving the pain and removing the diſeaſe, without any untoward circumſtance enſuing. Dr. Kinglake maintains, that the inflammation of gout is to be treated upon the ſame principles as other local inflammations, and yields to the ſame treatment. That this propoſition is correct, while the conſtitution remains unbroken, we fully believe; but to what extent the principle will hold, in thoſe whoſe ſyſtem is greatly debilitated and decayed, as well by age as by frequent and protracted diſeaſe, remains as yet undetermined by experience. With the diminiſhed ſtrength of the patient, the paroxyſms become diminiſhed in violence, and active remedies are, therefore, the leſs required; but from what we have detailed above, it appears at leaſt highly probable that, in the firſt attacks of gout, the application of cold, judiciouſly employed, ſo as to remove the morbid heat and no longer, would always be ſafe, and would contribute as well to ſhorten the paroxyſm, as to diminiſh the ſuffering of the patient, and to preſerve the joints from the injury, which protracted inflammation and morbid effuſions neceſſarily occaſion.

The operation of *purgatives*, which is known to be eſſentially uſeful in other inflammations, has been conſidered as beneficial in the gout by ſome phyſicians, but has more commonly been altogether forbidden. Sydenham expreſſes himſelf very ſtrongly in prohibition of purging, at any period of the fit, or even in the interval of health. Had he expreſſed his conviction upon this point ſimply as the reſult of experience, we ſhould have been diſpoſed to bow to his authority: but his theory appears to have had at leaſt an equal ſhare in producing this conviction; and unfortunately this theory involves the moſt groſs contradiction. In the beginning of the paroxyſm, we are told that there is great danger leſt purgatives ſhould ſtop the inflammation of the foot, "by throwing back into the maſs of blood that *peccant matter*, which nature was protruding to the extreme parts." (Tractat. de Podagra.) But after the termination of the fit, there is extreme danger, "leſt a new paroxyſm in the foot, equally ſevere with the former, ſhould be produced by a purgative." (Ibid.) So that this theory blows hot and cold, like the ſatyr in the fable; and theſe dangerous purgatives draw the *peccant matter* out of the foot, when it happens to be in, and are the moſt effectual means of throwing it into the foot after it has been driven out not only from the foot, but from the whole body (according to the hypotheſis) by nature!

Sydenham, however, lived long enough to retract, in part, his opinion reſpecting the injurious influence of purgatives in the gout, eſpecially if the milder ones are uſed, and an anodyne given after the operation. (Diſſert. de Mictu Sanguineo, &c. 1686.) Van Swieten obſerves, "many phyſicians are of opinion, that part of the gouty matter may be carried off by purgatives, and the fit rendered much more mild, eſpecially if it be occaſioned from errors in diet;" and he quotes Hoffmann, who recommends gentle purgatives in all caſes of local pain, and has mentioned an inſtance in his own perſon of the moſt ſtriking benefit derived from a purgative taken immediately before the fit of gout. An inſtance has been related to us, in which the gout was completely baniſhed, during a ſpace of nearly twenty years, by the uſe of a briſk purgative, taken when the firſt ſymptoms of the fit began to appear; the medicine employed in this inſtance conſiſted principally of ſcammony, in the doſe of about fifteen grains. We have ſeen this medicine uſed in a few caſes, with ſome relief, in ſmaller doſes, and without any untoward conſequences. That purgatives, as well as cold applications, may be reſorted to with advantage in the beginning of the paroxyſm of gout wherever the conſtitution is unimpaired, we conſider as tolerably well eſtabliſhed on the grounds of obſervation; although we do not doubt that many of the caſes of repelled gout, which have been attributed to ſuch cauſes, may have really occurred, under circumſtances of broken and feeble conſtitution, or of peculiar idioſyncraſy. But the accidents ariſing from a careleſs or injudicious abuſe of any practice, afford no juſt argument againſt the rational and cautious uſe of it.

We apprehend, however, that many diſorders have been very erroneouſly attributed to repulſion of the gout, which might be more correctly explained upon other grounds. For every inflammatory diſeaſe that occurred, even at the diſtance of ſeveral months from the ceſſation of the fit, has been conſidered as the reſult of the premature cure of the gout: whereas, it is next to impoſſible that ſo long an interval could have taken place between the cauſe and its effect; and, on the other hand, as gout is moſt frequent in plethoric habits, which are alſo moſt liable to inflammatory diſeaſes, the occurrence of pleuriſy or apoplexy, in ſuch caſes, is doubtleſs to be attributed to the plethora, and not to the previous gout. Dr. Cullen mentioned that he had known about twenty perſons die ſuddenly, more than half of whom were of gouty habits.

The violence of the pain, in the paroxyſm of gout, would naturally ſuggeſt the uſe of opiates: but experience has ſhewn that opium, in any form, when adminiſtered in the beginning of any inflammatory diſeaſe, with which much heat of ſkin and great febrile excitement are connected, generally fails to give relief; on the contrary, that it tends to increaſe the heat, fever, and reſtleſſneſs, and, with them, the pain likewiſe. When, however, the violence of the paroxyſm is ſomewhat abated, yet continues to return, ſo as to occaſion painful and reſtleſs nights, opiates may then be given with ſafety and with advantage, eſpecially in the caſe of perſons advanced in life, and who have been often affected with the diſeaſe. The hypothetical objection to the uſe of opiates, that they tend "to lock up the morbid matter," is altogether groundleſs. Dr. Warner ſpeaks with delight of the ſoothing influence of opium in the fits of gout, which he ſuffered in the latter periods of his life. (P. 133—136.)

Hitherto we have ſeen that the practice, generally purſued in the paroxyſm of gout, is merely palliative; an actual cure being deemed a deſideratum by moſt perſons, and a thing improper to be attempted by others. Of late, however, a medicine has been introduced into this country from France, which is ſaid to poſſeſs a ſpecific power over the gouty paroxyſm, which it removes "cito, tuto, et jucundé." The compoſition of this medicine is at preſent unknown, but it has been aſcertained that it is a vegetable matter, and it is ſaid by the inventor to be a plant heretofore not uſed in medicine. It is called *eau medicinale d'Huſſon.*[†] It has appeared, in many inſtances in which it has been employed in this country, and that in perſons of the firſt rank and character, to poſſeſs the power of removing the paroxyſm of gout in the courſe of twenty-four hours, leaving the patient in a ſtate of good health, and in poſſeſſion of the ſame uſe of his limbs which he enjoyed before the fit. It is ſaid that, in general, it increaſes the various excretions conſiderably, if taken in the full doſe, producing ſeveral looſe motions from the bowels, a free perſpiration, and an increaſed diſcharge of urine. But the influence of the medicine on the gouty paroxyſm is not attributed to theſe evacuations; ſince, in ſome inſtances, in which a ſmaller doſe was taken, a ſimilar relief to the gout was procured, without any increaſe of the excretions. No untoward circumſtance whatever has yet occurred, in conſequence of the ſpeedy removal of the paroxyſm: but farther experience will be requiſite to enable us to form a ſatisfactory eſtimate of its properties. (See an Account of the Eau Medicinale d'Huſſon, by Edwin G. Jones. M. D. Lond. 1810.)

Treatment in the Interval.—Whatever method is adopted in the treatment of the fit of gout, whether it be merely palliative, or ſo active as to ſhorten the attack, the conſtitution retains its prediſpoſition, and is equally liable to ſuffer a return of the diſeaſe. It is not yet aſcertained, we believe, whether the fits, when warded off by the *eau medicinale*, do not recur more frequently. It is the treatment of the patient in the interval of health, by which alone the diſeaſe can be *cured*, *i. e.* the paroxyſms prevented from returning, and the gouty diatheſis eradicated. How this is to be effected, we cannot learn from a view of the proximate cauſe, or eſſential nature of the diſeaſe; for upon this point we have no actual knowledge: but, as we poſſeſs ſome knowledge of the exciting cauſes of the diſeaſe, or of the circumſtances which generate or foſter the prediſpoſition to its attacks; ſo, by removing theſe, we may hope to prevent the production of that prediſpoſition, or to diminiſh it, if not to remove it altogether. Now, we have ſeen that intemperance and indolence are the parents of the gouty diatheſis, where it is not hereditary, and are the chief agents in exciting it to activity, where it is. The inference, then, is obvious: by *temperance* and *activity*, and not by medicine, the return of the gouty paroxyſms is principally to be prevented.

There is, perhaps, no ſubject, on which Engliſhmen in general entertain ſo many unfounded prejudices, or liſten to argument with ſo little attention or conviction, as that of *temperance*. It is conceived that phyſicians, in inculcating the advantages of it, only talk idly about it, in the way of their profeſſion; and that what is called good living, when not carried to actual debauch, is favourable to the ſupport and health of the body. It is, indeed, ſo univerſally the practice, in this country, to indulge an artificial appetite, beyond the actual wants of nature, that temperance is a thing, as Dr. Cadogan obſerves, of which an Engliſhman can acquire no idea at home. It is, however, altogether comparative with reſpect to individual conſtitution; for ſome perſons will become plethoric to a morbid degree, upon diet which is barely ſufficient to ſupport life in others. Perhaps Dr. Cadogan's teſt is correct. "As long as a man eats and drinks no more than his ſtomach calls for," (*i. e.* when unexcited by variety of diſhes, by ſauces and condiments, or by interpoſing liquor of any kind) "and will bear without the leaſt pain, diſtention, eructation, or uneaſineſs of any kind, &c. he may be ſaid to live in a very prudent well-regulated ſtate of temperance, that will probably preſerve him in health and ſpirits to great old age." (On the Gout, p. 31)

We know too well, however, the general want of power or inclination to reſiſt the pleaſures of the table, with that degree of perſeverance and to the requiſite extent, to expect that many cures of the gout will be effected in this way; but this we may aſſert, that the only inſtances of the eradication of the diſeaſe, which are known, have been accompliſhed by rigid and perſevering temperance. Dr. James Gregory, the preſent profeſſor of medicine in the univerſity of Edinburgh, is a remarkable example of the perfect cure of the gout by ſuch means. Born of gouty parents, he was attacked ſeverely when young, and ſuffered ſeveral paroxyſms, which, after being baniſhed by abſtemious living, recurred on a ſhort indulgence on reviſiting Oxford; but he has ſince that time entirely kept the foe at a diſtance for about thirty years, by extreme temperance and much exerciſe, and is now hale and ſtrong, though advanced ſeveral years beyond the age at which his father died, broken down by the gout. This he repeats annually to his pupils with no ſmall exultation. His diet has been chiefly broth, or a ſparing quantity of plain animal food, with little or no wine. Dr. Cadogan affords another inſtance of the benefit of rigid temperance in his own perſon, "having not only got rid of the gout," he ſays, "of which I had four ſevere fits in my younger days, but alſo emerged from the loweſt ebb of life, that a man could poſſibly be reduced to by colic, jaundice, and a complication of complaints, and recovered to perfect health, which I have now uninterruptedly enjoyed above ten years." (Loc. cit. p. 83.) Dr. Heberden likewiſe obſerves, that although complete cures of the gout are extremely rare, yet he has ſeen more than one inſtance in which, by a total abſtinence from animal food and wine, the patients were reſtored from a ſtate of extreme debility and miſery, to ſuch a degree of health and ſtrength, as rendered their life no longer uſeleſs to others, nor painful to themſelves. Comm. p. 44.

It can ſcarcely be doubted, indeed, that a complete cure of the diſeaſe might, by a rigid plan of life, be accompliſhed in moſt caſes, when the patients are not above the age of 30 or 35 years, even if they ſhould already have experienced two or three paroxyſms. In older habits, where the diſeaſe is of longer ſtanding, a complete cure cannot be ſo confidently anticipated; but experience has ſhewn that the ſeverity and the conſequent evils of the diſeaſe may be effectually mitigated by temperance, even under ſuch circumſtances. It is a moſt dangerous and miſtaken notion that the gout is to be encouraged; for its tendency is to increaſe in frequency, and in duration, to cripple the limbs, and to render the body liable to a variety of diſorders, which tend to render life both ſhorter and more miſerable than it would otherwiſe be.

The fear of the pernicious conſequences of rigid temperance is an unfounded prejudice, very prevalent in this country; but if there be any danger, it can only originate in general from the ſuddenneſs with which an extreme change is made. We have ſeen, in the caſe of the fat miller of Billericay, however, what a ſmall quantity of nutriment is abſolutely requiſite for the wants of the conſtitution, and how beneficial even an extreme change of diet ſometimes proves. (See Corpulence.)

The next point of management in the interval, which, together with temperance, conduces to the prevention of the recurrence of gout, is *exerciſe*. This tends to obviate plethora, on the one hand, by promoting the circulation and all the ſecretions, and to ſtrengthen the ſtomach, on the other hand, and promote the function of digeſtion; and plethora and indigeſtion, as we have already ſtated, commonly precede the gouty paroxyſm, and are connected with the gouty diatheſis. By thoſe who cannot walk, which is the beſt mode of exerciſe for the gouty, riding on horſeback, or even in a carriage, ſhould be ſubſtituted. Even friction, where theſe modes of exerciſe cannot be reſorted to, may be an uſeful ſuccedaneum. Dr. Cadogan's directions on this head are worthy of attention. If the patient "can neither walk nor ride at all, he muſt by degrees be brought to do both by the aſſiſtance of others, which may be given him in the following manner: let a handy active ſervant or two be employed to rub him all over, as he lies in bed, with flannels, or flannel gloves, fumigated with gums and ſpices, which will contribute greatly to brace and ſtrengthen his nerves and fibres, and move his blood without any fatigue to himſelf. This may take up from five to ten minutes at firſt, but muſt be repeated five or ſix times a day, ſuppoſing him totally unable to help himſelf. But if he can walk a hundred yards only, it will forward him greatly to walk thoſe hundred yards every two hours; and if he can bear a carriage, let him go out in it every day, till he begins to be tired. The firſt day or two all this may diſturb and fatigue him a little; but if he has patience to perſevere to the fourth, I dare promiſe him ſome amendment and increaſe of ſtrength; which he muſt employ, as young merchants do a little money, to get a little more. Thus he muſt go on rubbing, walking, and riding a little more and more every day, ſtopping always on the firſt ſenſation of wearineſs to reſt a little, till he be able to walk two or three miles at a ſtretch, or ride ten without any wearineſs at all." He muſt ever remember, however, that the habit of body is only to be corrected by habitual meaſures; and perſeverance, therefore, muſt be his motto in regard to exerciſe, not leſs than with reſpect to temperance. But it muſt be obſerved, in general, that the exerciſe ſhould not be violent; for if violent, it cannot be long continued, and muſt always endanger the production of atony and debility in proportion to the degree of violence. "It muſt be moderate," to uſe the words of Dr. Cullen, "but at the ſame time conſtant, and continued through life."

It has been ſuppoſed by ſome perſons, that an abſtemious and active mode of life for a limited time, as for inſtance, an abſtinence from animal food and fermented liquors, and a diet of milk and farinaceous matters alone, for the ſpace of one year, might be ſufficient for a radical cure of the gout. Such an opinion was expreſſed by Celſus, who ſays that "ſome, by cleanſing themſelves thoroughly by drinking aſſes' milk, have for ever baniſhed the diſeaſe; and others, by abſtaining, during a whole year, from wine, mulſe, and venery, have obtained a ſecurity from it for the remainder of their lives." (De Medicina, lib. iv. cap. 22.) In a few caſes, this plan may poſſibly have ſucceeded; but it is well known that many perſons, who, by entering on an abſtemious courſe, had been delivered from the gout, have, on returning to their former mode of living, had the diſeaſe return with at leaſt equal violence.

While an abſtemious regimen, combined with exerciſe, will tend to correct the gouty habit, if ſteadily purſued; it will be at the ſame time adviſable to avoid as much as poſſible ſome of thoſe circumſtances, which we have mentioned above as among the frequent exciting cauſes of the diſeaſe; more eſpecially when the gouty habit has become eſtabliſhed by a repetition of the fits, or is hereditary in its origin. In ſuch caſes, the meaſures, which we have propoſed, are not eaſily purſued to the requiſite extent, and are commonly attempted even with reluctance: men, therefore, have been very deſirous to find a medicine which might anſwer the purpoſe, without requiring a reſtraint on their manner of living. Of this deſire numerous empirics and ſelf-intereſted pretenders have taken advantage, and have been induced either to amuſe the gouty with inert medicines, or have raſhly employed thoſe of the moſt pernicious tendency. It is unneceſſary for us to inquire into the nature of thoſe alleged *ſpecific* noſtrums, which, after being for ſome time in vogue, were neglected or exploded, as their inutility or injurious qualities were thus acknowledged. But after premiſing that we are much diſpoſed, with Dr. Cullen and others, to believe the impoſſibility of curing the gouty habit by medicines, we ſhall notice one or two known medicines, which have been in vogue no long time ago. If the gouty conſtitution is created by a ſeries of high-feeding and indolence, how is it to be expected that medicine can change that conſtitution, eſpecially while the cauſe continues to operate?

The *Portland powder* is a medicine which obtained conſiderable reputation, as a cure for the gout, about the middle of the laſt century. This powder derived its name from the duke of Portland, who received ſo much relief from it, that he ordered the formula to be printed, and delivered to all who ſhould aſk for it. It was brought from Switzerland by a friend of the duke's. The powder conſiſts of the roots of ariſtolochia rotunda and gentian, and of the tops and leaves of germander, ground-pine, and centaury, well dried and powdered, equal weights. This powder was ordered to be taken for a year or two, at firſt in the doſe of a drachm daily, but afterwards in ſmaller quantities. (See Medical Obſ. and Inquir. vol. i. art. 14.) In the work juſt referred to, Dr. Clephane has ſhewn that a ſimilar compoſition was uſed by the ancients for the cure of gout. Such a formula is given by Galen, in his treatiſe De Antidotis, lib. ii. cap. 17., which he ſays he had uſed himſelf. Cælius Aurelianus ſpeaks of ſimilar medicines, under the denomination of *annalia medicamina*, from their being taken for the ſpace of a year. Aëtius gives, among other gout medicines, an "antidotus podagrica ex duobus centaureæ generibus," which differs from the Portland powder in one ingredient only. But ſeveral of the ancients conſidered the long uninterrupted uſe of theſe medicines as dangerous; and aſſure us that they are extremely hurtful in the hot and bilious, and are only proper in cold and phlegmatic conſtitutions. The Portland powder has fallen into neglect, under a notion that it was ultimately prejudicial. "In every inſtance," ſays Dr. Cullen, "which I have known of its exhibition for the length of time preſcribed, the perſons who had taken it were indeed afterwards free from any inflammatory affection of the joints: but they were affected with many ſymptoms of the atonic gout; and all, ſoon after finiſhing their courſe of medicine, have been attacked with apoplexy, aſthma, or dropſy, which proved fatal." (Firſt Lines, par. 557.) Dr. Heberden, however, is of opinion, that the popular prejudices againſt this medicine at preſent are as far beyond the truth, as they formerly were in its favour. (Comment. p. 48.) He attributed to it conſiderable powers of alleviating the diſeaſe, by ſtrengthening the ſtomach and ſupporting the function of digeſtion; and believes that many of the evils (which, becauſe they followed its exhibition, were imputed to its operation,) were in reality the conſequences of the diſeaſe, and not of the remedy. That thoſe caſes, however, of apoplexy, &c., which, it is admitted, occur in gouty habits, would be probably accelerated, if not occaſioned, by the uſe of a ſtomachic powder, while the full diet was continued, appears to be extremely probable: for the plethora muſt have been increaſed in proportion to the artificial increaſe of the digeſtive powers. We ſhould, therefore, be diſpoſed to conclude, that the conſtant uſe of ſuch a medicine muſt be pernicious, unleſs it were combined with temperance in eating and drinking; and that, with ſuch a regimen, it would in all probability be highly beneficial, if taken whenever the ſymptoms of indigeſtion ſhould appear.

Another claſs of remedies has been employed in the interval between the paroxyſms of gout, and in many inſtances with conſiderable alleviation to the diſeaſe, rendering the fits milder, and the intervals between them longer: we allude to the *antacids*; ſuch as the alkalis, and abſorbent earths. The nature of the chalky matter, produced in inveterate gout, which is an acid, and denominated lithic or uric acid, (being the ſame which is found in the urine and urinary concretions,) has led to the theory, that this acid, or its elements, is the morbific humour of the gouty; and therefore naturally ſuggeſted the idea of uſing alkaline medicines as remedies for the diſeaſe. And as aceſcent drinks are found to increaſe the gouty diatheſis, and to increaſe the diſordered ſtate of the digeſtive organs; ſo alkaline medicines have been found to relieve the ſymptoms of indigeſtion, and at the ſame time to leſſen the diſpoſition to gout. Thus the cauſtic alkalis have been found beneficial; but not more ſo, we believe, than the mild or carbonated alkalis, eſpecially potaſs; and the abſorbent or alkaline earths have likewiſe afforded relief, and ſometimes ſpeedily removed ſome of the urgent ſymptoms of diſordered ſtomach; eſpecially the preparations of chalk, lime-water, and magneſia. The magneſia is perhaps one of the beſt medicines of this ſort for the gouty, as it not only corrects the acidity of the ſtomach, but at the ſame time is laxative to the bowels, and thus contributes to obviate plethora. When theſe antacids do not ſufficiently open the bowels, or do not prevent coſtiveneſs, a little rhubarb, aloes, or ſome other aromatic purgative ſhould be conjoined with them. It appears, from ſome experiments made by Mr. Home and Mr. Brande, and recently publiſhed in the Philoſophical Tranſactions, (Part I. for 1810) that magneſia has a much more powerful influence in preventing the formation of the uric acid, in the urine, than any of the alkalis; it is probable, therefore, that it may be more beneficial in the gout. As a warm laxative the tincture of guaiacum was much recommended, and as it combines a ſtimulant with an evacuant property, it may be ſerviceable in ſome conſtitutions.

Cure of the irregular Gout.—We have already remarked, that falſe theory has led to much falſe alarm, and doubtleſs to many miſtakes in practice, eſpecially relative to the atonic gout; all the various ſymptoms of dyſpepſia, and hypochondriaſis being often ſuppoſed to be gouty, when no actual gout had ever appeared. Hence fomentations, bliſters, rubefacients, and other local ſtimulants to the extremities, the Bath waters, hot pediluvia, &c. have been employed to bring on the gout in the feet, inſtead of relying on the remedies which might reſtore the functions of the digeſtive organs. The Bath waters are certainly to be recommended in thoſe caſes, as they are poſſeſſed of conſiderable powers in reſtoring the healthful condition of the ſtomach, eſpecially when it has been diſordered by irregular and intemperate living; and of relieving thoſe wandering pains, which are deemed gouty, but which, as Dr. Heberden obſerves, are the common accompaniments of declining years and a broken conſtitution.

In theſe caſes of atonic or wandering gout, as it is called, all the means uſually employed to ſtrengthen the habit in general, and the ſtomach in particular, are to be reſorted to. Moderate, but frequent and regular exerciſe on horſeback, or walking, muſt be purſued; the diet ſhould be a little more generous, and ſome wine may be neceſſary; but both food and drink of the aceſcent kind muſt be ſhunned, and if wine, of whatever ſort, ſhould be found to increaſe the acidity of the ſtomach, ſpirits much diluted with water ſhould be ſubſtituted. At the ſame time, for the purpoſe of ſupporting the tone of the ſtomach, preparations of iron, the Peruvian bark, bitters, and aromatics in moderation may be reſorted to; and laxatives, employed only ſo as to prevent coſtiveneſs, muſt be taken. The propriety of frequent gentle vomits, where the indigeſtion is troubleſome, is more than problematical; for, while they give a temporary relief, by removing a load of undigeſted food, they tend to debilitate the organ, and thus to increaſe the evil which they were intended to remove. At the ſame time, all the cauſes of debility formerly mentioned, muſt be ſhunned, and expoſure to cold eſpecially muſt be carefully avoided: the moſt certain means of doing this is by repairing to a warm climate during the winter ſeaſon.

Cure of miſplaced or retrocedent Gout.—Theſe, like the atonic gout, are in a conſiderable degree the bugbears of medical ſpeculation, more eſpecially the miſplaced gout; they do, we believe, occaſionally occur in caſes of old and inveterate gout, but certainly much more rarely than is generally believed. This opinion Dr. Heberden ſtates from his own experience. (Comment. p. 41.—See alſo "Letters on the Cauſe and Treatment of Gout," by Dr. Robert Hamilton, Lynn, 1809.) The laſt mentioned phyſician, who had employed bleeding and other antiphlogiſtic remedies, both upon himſelf and ſeveral of his friends for eighteen years, never ſaw any thing like a retroceſſion of gout; and Dr. Cullen never ſaw an inſtance of miſplaced gout.

When the gout has diſappeared in the extremities, the ſtomach and bowels are ſometimes attacked with moſt acute pain, which is of a ſpaſmodic nature, and to be relieved only by ſtrong diffuſive ſtimulants, and opium in full doſes. Opiates are doubtleſs the moſt effectual antiſpaſmodics; but their operation will be aided by combining with them the ethers, volatile alkali, the free uſe of ſtrong wines, and aromatics, given warm, or ardent ſpirits, if theſe are not effectual. Camphor, muſk, aſſafœtida, and other ſtrong ſmelling ſubſtances, may be employed as adjuvants, eſpecially in leſs violent caſes. External heat to the region of the ſtomach, hot pediluvia, or the warm bath, will contribute by their ſtimulant powers to overcome the ſpaſms and pain. If the ſtomach is known to be loaded, as by a previous repaſt, its contents may be evacuated upwards, by draughts of warm water, with wine, or of chamomile tea, or downwards by means of ſome of the cathartic tinctures, as of ſenna, or rhubarb.

As thoſe perſons, who are ſubject to paroxyſms of the gout, are generally plethoric in their habits, ſo they are liable to inflammatory diſeaſes: and it cannot be doubted, that ordinary attacks of inflammation of the lungs, of palſy, and apoplexy, have been deemed gouty, and have proved fatal from the omiſſion of blood-letting. When the ſymptoms of pleuriſy, or peripneumony, or the acute pain of head, vertigo, ſomnolency, threatening apoplexy, or the actual ſymptoms of apoplexy and palſy occur; we ought not to delay the exhibition of the uſual remedies for thoſe diſeaſes, or be induced to be ſparing in the uſe of the lancet, becauſe we apprehend a gouty diatheſis; for death may be produced in a few minutes. And, as Dr. Heberden juſtly obſerves, "where the danger is imminent, from the violence of the ſymptoms, and we are doubtful whether they be gouty or inflammatory, we incur much greater riſk by omitting blood-letting in a diſeaſe ariſing from inflammation, than by drawing blood in a diſeaſe ariſing from gout." Indeed thoſe very phyſicians, who condemn bleeding and other evacuations in gout, in the extremities, gravely preſcribe the prompt adminiſtration of theſe remedies, when the lungs, head, or other viſcera are attacked with it. In a word, when the internal viſcera are affected with unequivocal ſymptoms of inflammation, the ſame treatment by local and general evacuation, bliſtering, &c. muſt be reſorted to, as in all other caſes of inflammation, regard being had at the ſame time (an obſervation, indeed, which applies to the practice of medicine univerſally) to the peculiar circumſtances of the patient's age, ſtrength, and conſtitution.

Gout-*wort*, in *Botany*. See Angelica.

GOUTIER, Gótre, or *Góître*, terms in *Surgery*, applied to a chronic enlargement of the thyroid gland. See Bronchocele and Goitre.

GOUTY-Land, in *Agriculture*, a term uſed by the farmers to denote a hollow fuzzy black earth, with little ſprings, that have no free outlet, and therefore ſwell and elevate the ſurface in many places.

GOUVEA, in *Geography*, a town of Portugal, in Eſtremadura; 20 miles S.E. of Viſeu.

GOUX de la Boulaye, Francis le, in *Biography*, a celebrated traveller, was born in the province of Anjou about the year 1610. Little is known of his early life, but that he felt a ſtrong propenſity for rambling into foreign countries: he employed ten years ſucceſſively in traverſing various parts of the globe. He ſeems to have been willing to become all things to all men, in order to obtain his wiſhes in ſafety. In Africa and many parts of Aſia he paſſed for a Mahometan, and in Europe he was a good Catholic. On his return, he publiſhed an account of his travels, under the title of "Les Voyages des Obſervations de François de la Boulaye le Goux, en divers Pays, d'Europe, d'Aſie, et d'Afrique, juſqu'a l'Année 1650." This work was publiſhed in 4to. and illuſtrated and adorned with engravings. The ſtyle is incorrect, but the facts, as far as they are borne out with truth, are ſaid to be very curious. He was ſo much altered in his perſon during his abſence from France, that his mother even, either could not, or would not recognize him, and he was obliged to inſtitute a law-ſuit to eſtabliſh his rights as heir in the family. In 1668 he was appointed ambaſſador to the Porte and the great mogul, by Lewis XIV. who was very deſirous of renewing his commerce with the Eaſt. Le Boulaye died in Perſia of a fever before he had executed this miſſion. Moreri.

GOUYE, Thomas, was born at Dieppe in the year 1650. He was brought up among the Jeſuits, and was at an early period diſtinguiſhed by an ardent love for mathematical and ſcientific purſuits. In 1699 he was elected a member of the Royal Academy of Sciences at Paris, of which body he became an aſſiduous attendant, and was highly eſteemed for the uſeful contributions which he made to their memoirs. He died at Paris in 1725, leaving behind him, as memorials of his learning and induſtry, "Phyſical and Mathematical Obſervations tending to the Improvement of Aſtronomy and Geography, ſent from Siam to the Academy of Sciences at Paris, by the Jeſuit Miſſionaries, with Reflections and Notes, in two volumes." The firſt volume was publiſhed in 1688, the ſecond in 1692, and both have been inſerted in the ſeventh volume of the collections of the Academy. Moreri.

GOW, in *Geography*, a town of Hindooſtan, in Bahar; 40 miles S.S.W. of Bahar. N. lat. 25 . E. long. 84° 48′.

GOWER, John, in *Biography*, an ancient Engliſh poet of the fourteenth century, is ſaid to have been deſcended from a family at Stitenham in Yorkſhire. He had the beſt education which the times afforded, and at a proper age became a member of the ſociety of the Inner Temple, where he attained to a high degree of reſpectability in the profeſſion of the law, and where he became acquainted with Chaucer. Some writers affirm that, in the courſe of his profeſſional duties he was appointed chief juſtice of the court of Common Pleas, though others think the judge was another perſon of the ſame name who was a contemporary with the poet. Gower attached himſelf to the duke of Glouceſter, uncle to Richard II., and was much noticed by the king himſelf, at whoſe deſire he wrote his principal work. He had, however, a pliable mind, and could turn his pen to different intereſts; for on the acceſſion of Henry IV. he not only wrote in adulatory terms to the new king, but even reflected on the miſ-government of the one who had been depoſed, and who had been his patron. His circumſtances were ſuch as to put him beyond the fear of want, for he appears to have been a liberal contributor to the rebuilding of the church of St. Mary Overy in Southwark. During the firſt year of Henry's reign, our poet had the misfortune to be deprived of his ſight, an affliction which he did not long ſurvive. He died in the year 1402, at a very advanced age. Gower, ſays his biographer, is entitled to a place among Engliſh writers only relatively to the time in which he flouriſhed; for though well furniſhed with learning, and a ſucceſsful cultivator of his native language, he has not the leaſt pretenſions to genius or invention. He is characterized by his friend Chaucer, as the "moral Gower;" he was uniformly grave, even upon topics that might inſpire vivacity. He was author of three volumes, entitled "Speculum Meditantis;" "Vox Clamantis;" and "Confeſſio Amantis." Of theſe, the firſt is a moral tract, and relates to conjugal duties; the ſecond is a metrical chronicle concerning the inſurrection of the people under Richard II., in Latin elegiac verſe: the third, or "Lover's Confeſſions," relates to the morals and metaphyſics of love. This is the only one that has been printed, and it was among the earlieſt products of the Engliſh preſs, by Caxton in 1483. It ſeems, ſays Mr. Warton, to have been his object to crowd all his erudition into this elaborate performance. The moſt intereſting part of the work is a variety of ſtories adduced as moral examples, and taken from authors moſt in vogue, ancient and modern. The language is perſpicuous, and the verſification frequently harmonious. Biog. Brit. Warton.

Gower, in *Geography*, a diſtrict of Wales, in the ſouth-weſtern extremity of Glamorganſhire, below the town of Swanſea, and bounded by the Iriſh ſea and the Briſtol channel.

Gower, *Cape*, a cape on the E. coaſt of China, lying in the track from the ſouthward to the gulf of Pekin. A reef of rocks runs out from a neck of land near this cape, which appeared to have a compact harbour. The entrance to it was between the cape and the reef juſt mentioned. When the perſons concerned in the embaſſy to China paſſed this cape, a conſiderable number of veſſels were deſcried in the harbour, and a pretty large town behind it. N. lat. 36° 57′. E. long. 122° 15′.

Gower's *Iſland*, a ſmall, flat, low iſland, in the Pacific ocean, ſo called by captain Carteret, who paſſed it in Auguſt 1767; he found no anchorage, and could only obtain a few cocoa-nuts in exchange for nails; the inhabitants reſembled thoſe of Egmont iſle. S. lat. 7° 56. E. long. 158° 56′.

Gower's *Harbour*, a bay on the S. W. coaſt of New Ireland; 5 miles N. of cape St. George. M. Bougainville calls this "Praſlin Bay," and by Dampier it is called "St. George's bay." S. lat. 4° 50′. E. long. 150° 48′.

GOWGAT, a town of Hindooſtan; 12 miles W. of Agra.

GOWGATCHY, a town of Bengal; 12 miles N. of Calcutta.

GOWN, Robe, a long upper garment, worn by lawyers, divines, and other graduates, who are hence called *gentlemen of the gown*, or *gown-men*.

The gown is an ample ſort of garment, worn over the ordinary clothes, hanging down to the feet. It is faſhioned differently for eccleſiaſtics, and for laymen.

At Rome, they give the name virile gown, *togas viriles*, to a plain kind of gown, which their youth aſſumed when arrived at puberty. This they particularly denominated *prætexta*.

In ſome univerſities, phyſicians wear the ſcarlet gown. In the Sorbonne, the doctors are always in gowns and caps. Beadles, &c. wear gowns of two colours.

Among the French officers, &c. they diſtinguiſh thoſe of the ſhort gown, or robe; which are ſuch as have not been regularly examined. They have alſo barbers of the ſhort gown, who are ſuch as are obliged to practiſe in an inferior way to ſurgeons, or thoſe of the long robe.

GOWN is alſo taken, in the general, for the civil magiſtrature, or the profeſſion oppoſite to that of arms.

In this ſenſe it was that Cicero ſaid, "Cedant arma togæ."

GOWRAH, in *Geography*, a town of Bengal; 27 miles S. S. E. of Doeſa.—Alſo, a town of Hindooſtan; 5 miles N. E. of Benares.

GOWRAN, a poſt town of Ireland, in the county of Kilkenny. It is a place at preſent of no importance, but was a borough before the Union, and there are ſome ruins which ſeem to intimate its former importance. It is 52 miles S. from Dublin.

GOWREY, a town of Hindooſtan, in Oude; 53 miles W. of Kairabad.

GOWRY-BIRD, in *Ornithology*, a name given by Edwards to the LOXIA *punctuloria*.

GOWRYPOUR, in *Geography*, a town of Bengal; 26 miles S. E. of Dacca.

GOWT, in *Engineery*, or go-out, is a name applied to the ſea ſluice, or valves uſed in embankments next the ſea or tidal rivers, for letting out the land-waters when the tide is out, and preventing the ingreſs of ſalt-water. Some of the gowts in the fens of Lincolnſhire and Cambridgeſhire are very large works, and coſt immenſe ſums of money.

GOY, in *Geography*. See ANGOI.

GOYANES, a town of Spain, in Gallicia, on the ſea-coaſt; 25 miles S. W. of Santiago. N. lat. 42° 32′. W. long. 8° 50′.

GOYAS, GOJAS, or *Goyaz*, a town and government of Brazil, extending from 42° to 54° W. long. and from 6° 30′ to 19° S. lat. the inhabitants of which are eſtimated at 8930 whites, 29,630 Indians, and 34,100 negroes, who are employed in ſearching for gold in the mines, which were diſcovered in the year 1726.

GOYAVA, a town on the W. coaſt of the iſland of Grenada. N lat. 12° 13′. W. long. 61° 31′.

GOYAVES, a town of the iſland of Guadaloupe, giving name to a bay in which it is ſituated.

GOYEN, JOHN VAN, in *Biography*, a painter, born at Leyden in 1596, who ſtudied ſucceſsfully the practice of landſcape-painting under ſeveral maſters, and having an uncommon readineſs and ſkilfulneſs of hand, he produced a great many works of a light agreeable kind; with much character of nature, but no great reliſh of art; which, in their time, however, were very highly eſteemed and widely ſpread over Europe.

Views of he ſcenes on the banks of the canals and rivers of the Low Countries were his favourite ſtudies; ſometimes he emerged to the ſea ſhore, or ſunk into the interior of the country, and ſketched the villages that preſented themſelves to his taſte in the one, or the harbours, &c. of the other; but all are touched by the ſame kind of pencilling, and generally in the ſame hue of colour, when he came to work them up into pictures. Certainly, they have much merit of a peculiar kind, ſuch as lightneſs in the handling, and freedom in their effect; but frequently they are vapid and flimſy, and by no means juſtify the high value and reputation affixed to them. It is ſaid that the grey tone, too frequently found in his pictures, aroſe from the uſe he made of Haerlem blue, which is apt to fade into that tint, and therefore no longer in uſe. It may be ſo; but that grey is not the predominant defect in his pictures: it is the evident haſte with which they are wrought, and their conſequent imperfection of imitation, that induces us thus to condemn what the world have too long eſtimated in a high ratio, which ought only be given to works completed with the ſkill and purity of taſte of a Caracci or a Claude. He died in 1656, aged 60.

GOZ, or GOZEN, in *Geography*, a ſea-port town of Morocco, on the coaſt of the Atlantic, in the vicinity of Mogodor.

GOZO, an iſland of the Mediterranean, ſituated N. W. of Malta, and at a little diſtance from it. This iſland is about 25 miles in circumference, rather fertile, and containing about 3000 inhabitants.

GOZO, or *Gaſda*, a ſmall iſland in the Mediterranean, about 27 miles from the S. W. coaſt of Candia; anciently "Clauda," near which St. Paul ſailed in his voyage to Rome. Some biblical writers ſuppoſe that the Gozo near the iſle of Malta is the Clauda of the Book of Acts. It is occupied by about 30 families; who have a Greek church, and is occaſionally viſited by veſſels for a ſupply of water and proviſions. At a ſmall diſtance to the weſt is a very little iſland called "Pulo Gozo," or Little Goz. N. lat. 34° 48′. E. long. 23° 46′. See CLAUDA.

GOZZANO, a town of Italy, in the department of the Gogna; 18 miles N. of Novara.

GOZZOLI, BENOZZO, in *Biography*, one of the early practitioners of the art of painting on its revival. He was a Florentine, and diſciple of Fra. Angelico; but ſubſequently imitated with very great ſucceſs the ſtyle of Maſſaccio, his contemporary. Vaſari ſpeaks of him with great eſteem under the name of Benozzo, and relates hiſtories of his many productions at Florence, Volterra, Rome, and Piſa; at which latter place are his moſt conſpicuous labours, both in hiſtory and portraits, which indeed at that time were uſually introduced in hiſtorical pictures. At Piſa he died in 1478, aged 78, and a monument, with a Latin epitaph, is placed near his principal work in the Campo-Santo; a memento of his powers, and the eſteem in which they were held.

GRAAF, REINIER DE, an excellent phyſician, was born at Schoonhove, a town in Holland, where his father was an eminent architect, on the 30th of July, 1641. He ſtudied phyſic at Leyden, where he made great progreſs, and at the age of 22, publiſhed his treatiſe "De Succo Pancreatico," which gained him conſiderable reputation. In 1665, he went to France, and received the degree of M. D. at Angers; but he returned to Holland in the following year, and ſettled at Delft, where his great ſucceſs in practice excited the envy of his profeſſional brethren. He married in 1672, and died in Auguſt, 1673, when he was only 32 years of age. He publiſhed three diſſertations relative to the organs of generation in both ſexes, upon which he had a controverſy with Swammerdam. His works were publiſhed in 8vo. at Leyden, in 1677 and 1705; they were alſo tranſlated into Flemiſh, and publiſhed at Amſterdam in 1686. Hutchinſon, Biog. Med. Eloy.

GRAAF REYNET, in *Geography*, a diſtrict of ſouthern

Africa, in the colony of the Cape of Good Hope, extending to the eaſtern extremity of the colony. On the E. it is divided from the Kaffers by the Great Fiſh river, the Turka, the Bambarſberg, and the Zuureberg; on the W. from the diſtricts of Zwellendam and Stellenboſch by the Camtoos river, the Gamka or Lion's river, and Nieuwveld mountains; on the N. from the Boſjeſman Hottentots by Plettenberg Landmark, the great Table mountain, and the Karreeberg; and on the S. it is terminated by the ſea-coaſt; the whole length and breadth of this diſtrict may be about 250 by 160 miles, making an area of 40,000 ſquare miles, which is peopled by about 700 families, each family commanding about 57 ſquare miles of territory. Great part of it has been occaſionally abandoned on account of the incurſions of the Kaffers and Boſjeſmans. The inhabitants are a ſort of Nomades, who would long ago have penetrated with their flocks and herds far beyond the preſent boundaries of the colony, if they had not been reſiſted by the Kaffers. The boors of this diſtrict are graziers; and it is entirely compoſed of loan-farms, which were grants made to the original ſettlers of certain portions of land to be held on reaſonable yearly leaſes, on condition of paying to government an annual rent of 24 rix-dollars. Barrow's Travels in S. Africa, vol. ii.

GRAAT, or GRAET BARENT, in *Biography*, an hiſtorical painter, whoſe name is remembered principally upon account of his cloſe imitation of the works of Bamboccio, and of his having founded an academy at Amſterdam, where he was born, to which the beſt artiſts of his time reſorted to ſtudy after living models; by which means much improvement was obtained, and ſpread among thoſe who cultivated taſte and ſcience in the arts. He died in 1709, aged 81.

GRAB, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 17 miles W. N. W. of Leitmeritz.

GRABATARII, GRABBATARII, in *Church Antiquity*, ſuch perſons as deferred the receiving of baptiſm till the hour of death; or who did not receive it till they were dangerouſly ill, and out of hopes of life: from an opinion, that baptiſm abſolutely waſhed away all former ſins.

The word is formed of *grabatum, bed;* and that from the Greek *κράββατον*, *a hanging bed*, of *κρεμαω*, *I ſuſpend:* ſuch as was the bed of ſlaves, poor people, Cynic philoſophers, &c. who are enemies of luxury and eaſe.

GRABAU, in *Geography*, a town of the duchy of Warſaw; 12 miles S. of Kaliſh.

GRABAW, a town of Auſtrian Poland, in the palatinate of Belcz; 28 miles N. N. W. of Belcz.

GRABE, JOHN ERNEST, in *Biography*, a learned divine, and editor of the Alexandrian manuſcript, in the Royal Library at London, was born at Koningſberg, in Pruſſia, in the year 1666. Here he received his education, and in due time took his degree of M. A. applying himſelf with all diligence to the ſtudy of divinity, and the peruſal of the fathers. He had been brought up in the Lutheran principles, but having imbibed ſome notions inconſiſtent with the commonly received faith, reſpecting the uninterrupted ſucceſſion of biſhops being eſſential to the exiſtence of the true church, he was ſummoned before his ſuperiors and impriſoned. Upon his releaſe, after a few months, he choſe rather to quit the church than abandon his opinion, and determined to become a member of the Catholic religion. He delivered, in a memorial to the electoral college at Sambia, in Pruſſia, in 1695, containing the reaſons for his change, and then left Koningſberg, that he might be at liberty to carry his plan into execution, in ſome place where he ſhould be beyond the reach of the Pruſſian juriſdiction. While he was on the road to Erfurt, through which he meant to paſs to a Catholic country, the elector of Brandenburg ſent three treatiſes to him in anſwer to his memorial, by three Pruſſian divines, written by order of the elector. This great attention of his ſovereign claimed the reſpect of Grabe, who not only read them with care, but felt deſirous of diſcuſſing the queſtion more cloſely before he formed his ultimate determination of abandoning the religion in which he had been educated. He accordingly wrote to one of the perſons that had anſwered his memorial, intimating a ſtrong wiſh to return to Berlin, that he might enjoy the benefit of a conference with him. This privilege was obtained for him; M. Grabe returned and was ſoon prevailed on to relinquiſh his purpoſe of joining the papal communion, but ſtill he maintained the obnoxious tenet for which he had ſuffered impriſonment. Finding him immoveable on this point, his friend adviſed him to remove to England, where, ſaid he, "you will find the outward and uninterrupted ſucceſſion which you want: take then your route thither: this ſtep will cauſe leſs uneaſineſs to your friends, and, at the ſame time, equally ſatisfy your ſcruples." He gladly complied with the advice, and was ſtrongly recommended to king William, who immediately granted him a penſion of 100*l.* per ann. to enable him to purſue his ſtudies. From this time he conſidered England as his country, becauſe he conceived that its eccleſiaſtical conſtitution approached nearer on the whole, than that of any other, to the primitive pattern. He ſhewed his gratitude for the liberal patronage which he received by the publication of ſeveral learned works. Having formed a deſign of printing ſome curious and ſcarce pieces of the fathers, in defence of his own opinions, he obtained acceſs to the univerſity of Oxford, to examine the treaſures of the Bodleian library, and, in 1698, he publiſhed "Spicilegium S. S. Patrum, &c." vol. 1. 8vo.; and in the following year, the ſecond volume of the ſame work appeared. Shortly after this, he was ordained a deacon of the church of England, and was appointed chaplain of Chriſt-church, Oxford. This promotion he accepted, in order that he might be entitled to the emoluments without being required to diſcharge the duties of the appointment, for he had refuſed, on his ordination, to receive the ſacrament, on account of the omiſſion of the prayer in the communion ſervice, mentioning the ſacrifice, before the elements were diſtributed, which had been inſerted in the firſt common-prayer book of king Edward VI., and he ever afterwards continued a non-conformiſt in this particular. In the ſame year in which he took orders, Mr. Grabe publiſhed "S. Juſtini Philoſophi et Martyris Apologia Prima pro Chriſtianis, &c." illuſtrated with the notes of ſeveral learned men, and additional remarks of his own; and in 1702 he publiſhed "S. Irenæi Epiſcopi Lugdunenſis contra omnes Hæreſes Libri quinque, &c." with prolegomena and notes. On the acceſſion of queen Anne to the throne, Mr. Grabe's penſion was continued, and her majeſty was adviſed to employ him in printing the Alexandrian MS. in the royal library, of the Septuagint tranſlation of the Old Teſtament. The queen took the opportunity of informing him of the appointment herſelf, and at the ſame time made him a handſome preſent as an encouragement to his exertions. In 1705, he publiſhed propoſals for printing that work by ſubſcription, ſetting forth the ſuperior value of this copy to the Vatican MS.; he alſo gave three ſpecimens, containing ſo many different methods for the projected edition, in the final choice of which he was to be determined by the learned world. As a teſtimony of their approbation of the deſign, the univerſity of Oxford preſented

ſented him with the degree of doctor of divinity. His propoſals met with a very favourable reception on the continent as well as in England, and he received a handſome preſent from his own ſovereign, the king of Pruſſia, and liberal ſubſcriptions from the principal nobility, clergy, and gentry of all parts. In 1707, he gave to the public his firſt volume, under the title of "Vetus Teſtamentum juxta Septuaginta Interpretes; tom. 1. continens Octateuchum." This volume contains the Pentateuch, and the three following books. In the expectation of an acceſſion of additional MSS. he deferred the ſecond and third volumes, and publiſhed the fourth volume in the year 1709. This contained the book of Pſalms, of Job, of the three books of Solomon, &c; and in the following year he publiſhed a Latin diſſertation, giving a particular account of the reaſons why he had departed from the uſual order of publication, and of the helps which he expected to receive in order to perfect his plan. Theſe were, a Syriac MS. of the hiſtorical books of the Old Teſtament, with Origen's remarks upon them, and two MSS. one belonging to cardinal Chigi, and the other to the college of Lewis XIV. When he received theſe MSS. and had collated them, he prepared a volume of annotations on the whole work, and collected materials for the Prolegomena. The time which theſe objects took, cauſed a material delay in the publication of the ſecond and third volumes, which did not, in fact, appear till after the author's death. This event took place in 1712, when he was only in the forty-fifth year of his age. He had previouſly to this publiſhed "An Eſſay upon the Arabic MSS. in the Bodleian library, and that ancient book, called the Doctrine of the Apoſtles, which is ſaid to be extant in them, wherein Mr. Whiſton's miſtakes about both are plainly proved." The third volume of his great work was publiſhed in 1719, and the fourth in 1720. On his death-bed he was attended by Dr. Smalridge, by whoſe means he deſired that the public might be informed that he died in the faith and communion of the church of England, though he conſidered its conſtitution to be defective in ſome points, in which he thought the nonjuring clergy adhered more cloſely to the apoſtolical doctrine and diſcipline. Of his talents there were different opinions, but of his induſtry and learning no one could harbour a doubt. Dr. Thirlby ſays, in the dedication of his edition of Juſtin's Apology, "he was a good man, and not unlearned, and well verſed in the writings of the fathers. But he was no critic, nor could be one, ſince he was not furniſhed with genius or judgment, or, to ſpeak the truth, with learning ſufficient for the purpoſe." In this opinion Le Clerc coincides, and adds, that his books gained him the character of a laborious perſon rather than that of a great critic. He was the author of many other works beſides thoſe which have been mentioned, and was editor of an elegant edition of biſhop Bull's works: he likewiſe aſſiſted in preparing for the preſs archdeacon Gregory's edition of the New Teſtament in Greek; and he left behind him many MSS. ſome of which have been publiſhed. Biog. Brit.

GRABEN, in *Geography*, a town of Croatia; 12 miles S. of Varaſdin.

GRABO, a town of Sweden, in Eaſt Gothland; 11 miles S.E. Linkioping.

GRABON, a town of the duchy of Mecklenburg, on the Elde; 80 miles N.W. of Berlin. N. lat. 53° 23′. E. long. 11° 44′.

GRABUSA, an iſland of the Mediterranean, near the N.W. coaſt of the iſland of Candy, confirmed to the Turks by the peace of Carlowitz, and generally garriſoned with 1000 men. N. lat. 35° 40′. E. long. 23° 33′.

GRABUT, in *Biography*, an obſcure French muſical compoſer, whoſe name is not to be found in the annals of the art. He was brought into England to flatter the partiality of Charles II. for the muſic of France; and employed by Dryden to ſet his political opera of "Albion and Albanius," though Purcell had already given indiſputable proofs of his ſuperior genius, and was rapidly riſing into fame and national favour.

This drama, written under the auſpices of king Charles II., was rehearſed ſeveral times, as the author informs us in his preface, before his majeſty, "who had publicly declared, more than once, that the compoſitions and choruſes were more juſt and more beautiful than any he had heard in England." We believe this prince was not very ſkilful in muſic, nor very ſenſible to the charms of any ſpecies of it but that of France, of the gayeſt kind; however, royal approbation is flattering and extenſive in its influence. Unfortunately for the poet and muſician, his majeſty died before it was brought on the ſtage; and when it did appear, the ſucceſs ſeems not to have been very conſiderable. Upon a peruſal of this drama, it ſeems hardly poſſible, ſo near a revolution, that it ſhould have eſcaped condemnation upon party principles; as, under obvious allegories, Dryden has laſhed the city of London, democracy, fanaticiſm, and whatever he thought obnoxious to the ſpirit of the government at that period. Had Orpheus himſelf not only compoſed the poem and the muſic, but performed the principal part, his powers would have been too feeble to charm ſuch unwilling hearers."

GRAÇAY, in *Geography*, a town of France, in the department of the Cher, and chief place of a canton, in the diſtrict of Bourges; 9 miles S.W. of Vierzan. The place contains 2204, and the canton 5459 inhabitants, on a territory of 145 kiliometres, in 9 communes.

GRACCHURIS, an ancient town of Hiſpania Tarragonenſis, mentioned by Livy, Antonine, and Ptolemy, and ſaid to be built by the proconſul Titus Gracchus Sempronius, after having conquered the Celtiberians. Others ſuppoſe that it exiſted before Sempronius, under the name of "Illurcis," and that he only repaired it. It is now called Arreda.

GRACCHUS, Tiberius Sempronius, in *Biography*, a perſon very memorable in the hiſtory of Rome, was the ſon of a father of the ſame name, a diſtinguiſhed commander, and excellent citizen, who, from the Plebeian ranks, arrived at diſtinguiſhed honours, and the higheſt offices in the ſtate, having been maſter of the horſe to the dictator, Junius, after the celebrated battle of Cannæ, afterwards conſul, and, at length, to complete his glory, he was ſlain while fighting for his country. The mother of the ſubject of this article was Cornelia, daughter of Scipio Africanus, whoſe character has been illuſtrated in the proper place. Tiberius received every advantage of education that the pious affection of a wiſe parent could beſtow, and his natural diſpoſition ſeconded the efforts of his inſtructors. He was modeſt, and remarkably mild in his temper; and became, at a very early age, diſtinguiſhed for eloquence, ſobriety, and political knowledge; and his reputation was ſealed by an admiſſion into the venerable college of augurs. It is mentioned, as a proof of the high character which he ſuſtained, that Claudius Appius, one of the moſt illuſtrious perſons in Rome, and preſident of the ſenate, offered him, ſpontaneouſly, his daughter in marriage, which he thankfully accepted. When Appius informed his wife what he had done, ſhe replied, "Why ſo ſuddenly, you might have taken time, even if Tiberius Gracchus were the man." In conformity with the Roman cuſtom, Tiberius paſſed his youth in military ſervice; firſt in Africa, under his brother-in-law, the younger Scipio, where he obtained great credit in the army, being equally beloved by thoſe above and thoſe below him. He was made queſtor, in the Numantian war, to the conſul C. Hoſtilius Mancinus. This was in the year B. C. 137: the campaign was unfortunate, and the Roman general was under the neceſſity of negociating a treaty of peace with the enemy. The Numantines, who had been betrayed in a former treaty by the Romans, refuſed to negociate, unleſs it were with Tiberius Gracchus, with whoſe character for probity and ſtrict honour they were well acquainted. This being admitted, a peace was immediately concluded. The treaty, though as favourable as, from circumſtances, could be expected, was received by the Romans with great indignation: they determined to annul it, and to deliver thoſe, who had been inſtrumental in making it, into the hands of the Numantines. The conſul was accordingly given up to them, naked and in chains, and it is probable that Tiberius Gracchus would have ſhared the ſame fate had not a powerful intereſt been exerted in his favour. A ſenſe of the injuſtice of the ſenate on this occaſion, and reſentment of the diſhonour they had thrown upon his treaty, was ſuppoſed to be a principal cauſe of the ſubſequent hoſtilities in which he engaged againſt that body. The condition of the Romans, at this period, afforded a good opportunity for the exertions of patriotiſm; for the great maſs of the lower claſſes of citizens were in a ſtate of abject poverty. Lælius the Wiſe, the friend of Scipio, had attempted to introduce ſome remedy for this evil, but the ſerious oppoſition of men in power had deterred him from the execution of his plan. Tiberius Gracchus reſolved to take up the cauſe. He was accordingly elected a tribune of the people, and propoſed a revival of the Licinian law, with certain modifications, which greatly ſoftened its operations. (See AGRARIAN LAW.) It offered a full compenſation out of the treaſury for all the land above the 500 acres allowed, which any one might be obliged to reſign to the public, and permitted every child of a family to hold 250 acres above the 500 held in the father's name. This propoſal was received, as it might be expected, by the ſuperior orders, whoſe rights and properties were to be affected by it: they were determined to ſtand by one another in reſiſting the innovation. On the other hand, Gracchus loſt no time in rouſing the people to a knowledge and aſſertion of their claims as men and members of ſociety. His ſpeeches were addreſſed to their intereſts and their feelings: his arguments were ſpecious and highly dangerous to the peace of thoſe whoſe wealth was become the object of popular diſcuſſion. In one of his harangues, he exclaimed, "The wild beaſts have their caves and dens, but the brave men who ſhed their blood in the cauſe of their country have nothing free but the air and the light. It is a mere mockery when their generals exhort them to fight for their ſepulchres and houſhold gods, when, perhaps, not a man among them is poſſeſſed of a domeſtic altar, or ſepulchre, of his anceſtors. The private men bleed and die to ſecure the luxuries of the great, and they are denominated the maſters of the world, while they are not owners of a foot of ground." At length, after much tumult in the ſtate, the Agrarian law was paſſed, and Appius Claudius, Tiberius Gracchus, and his younger brother Caius, were appointed commiſſioners to carry its proviſions into execution. In his progreſs in the buſineſs he was embarraſſed with many obſtacles, and, on his part, he took meaſures effectually to thwart the purpoſes of the great; and, by new laws which he got enacted, he rendered the property of all the old families inſecure. The difficulties which occurred in carrying the new law into effect were ſuſpended by the death of Attalus, king of Pergamus, who made the Roman people his heirs. Gracchus procured a law for the diſtribution of his treaſures among the poorer citizens, and for the diſpoſal of the revenues of Pergamus, not by the ſenate, but by the aſſembly of the people. Theſe meaſures gave him a great degree of influence among the citizens, and he conceived the deſign of ſecuring the powers of which he felt himſelf poſſeſſed, by raiſing his father-in-law to the conſulate, his brother to the tribuneſhip, and continuing to himſelf the ſame office another year. He alſo planned other regulations for abridging the authority of the patricians, and throwing more weight into the popular ſcale. The day of election was approaching, and the ſenators reſolved to make a ſtand againſt the innovations which he propoſed, and a conſpiracy was openly formed to take away the life of Tiberius Gracchus. Of this he was informed by a friendly ſenator, as he was proceeding to the capitol. He, nevertheleſs, advanced, and his party prepared to repel force by force. In the uproar, he attempted to ſpeak, but his voice could not be heard. He made ſigns to his friends, by raiſing his hand to his head, to ſhew that his life was in danger. This ſignal was inſtantly interpreted by his enemies as a demand of the regal crown, and Scipio Naſica, the inveterate enemy of Gracchus, cried out "Since we are betrayed by our conſul, let thoſe who love the republic follow me." A general conteſt now commenced. The adherents of Gracchus were quickly diſperſed, and himſelf was diſpatched with a thouſand blows. Not leſs than 300 perſons were ſlain in this commotion, and the bodies of the dead, even that of Gracchus himſelf, were ignominiouſly thrown into the Tiber. Several of his friends were afterwards baniſhed, and not a few put to death, without the form even of trial, and the ſenate paſſed an act of indemnity for all thoſe who were concerned in the maſſacre. The people, however, indignant againſt his enemies, drove Naſica from Italy, and would never permit him to return. With reſpect to Tiberius Gracchus, his character has been celebrated either as that of a martyr to liberty, or as a victim to lawleſs ambition, according to the different principles of thoſe who have commented on his actions. Many have thrown on his memory reflections as unmanly as they are ſevere. It ſeems to be acknowledged on all hands that he poſſeſſed great talents, and was eſteemed for his private worth. That he was a man of ambition none will deny, and it may be that a love of popularity ſuggeſted the great meaſures which he propoſed; nevertheleſs, the hiſtorian may be ſafely followed, who ſays, that he was actuated by the beſt intentions, but that he proſecuted his deſign with too much violence.

GRACCHUS CAIUS, brother to Tiberius, but his junior by nine years, enjoyed the ſame advantages of education with his brother, which he ſo well improved as to become one of the ableſt orators of his time. Cicero ſays of him, that he knows not if he had his equal in eloquence, and recommends his compoſitions, though unfiniſhed, to the ſtudy of youth. After the tragical end of his brother, Caius paſſed ſome time in retirement, cultivating his rhetorical talents, and ſecretly preparing to act his part on the theatre of the public. In the year 126 B. C. he accompanied the conſul Aurelius Oreſtes to Sardinia as his queſtor, and obtained great applauſe, as well for his humanity and temperance, as for a ſtrict attention to the duties of his office. The ſenate ſhewed evident ſigns of jealouſy on account of the popularity which he acquired, and retained him as proqueſtor in Sardinia in order to keep him at a diſtance from the Roman forum. Perceiving their intentions, he ventured, in defiance of their orders, to quit the iſland without leave of his commander, and ſuddenly made his appearance at Rome. He was called to account for this breach of military diſcipline, but was readily acquitted. Soon after he became a candidate for the tribuneſhip, and ſuch was the zeal of the people in his favour, that the Campus Martius was not able to contain the multitude who flocked from the Italian towns to ſupport his election, and many gave their votes from the tops of the adjacent houſes. Caius had not forgotten the enemies of Tiberius, and would have purſued them to their deſtruction, but was probably diſſuaded from it by his mother. His ſpeeches were calculated to revive the indignation of the people againſt the ſenators for their conduct towards Tiberius, and he propoſed and carried motions for confirming his brother's laws, and the paſſing of others ſtill more obnoxious to the patricians. He was appointed commiſſioner for the diviſion of lands among the poor citizens and allies, and in his progreſs through Italy he employed his talents and wealth in repairing roads, building bridges, and in other works equally uſeful and important. He eſtabliſhed public granaries in Rome, from which the citizens were to have their monthly diſtributions of corn at a low price, the expences of which were to be defrayed by duties laid on goods imported into the dominions of the late king Attalus. By theſe, and other acts of a like kind, he ſo ingratiated himſelf with the people, that he was choſen a ſecond time tribune. Triumphing in his ſucceſs, he propoſed a law for transferring from the ſenators to the knights the cognizance of all private cauſes. When he had obtained his purpoſe he exclaimed, "at length I have humbled the ſenate." He now felt himſelf the arbiter of the republic, and treated the patricians with contempt. This behaviour haſtened his ruin. There is a point, beyond which the moſt ſucceſsful man, whatever be his pretenſions, cannot go with ſafety. Caius had tranſgreſſed this boundary, and his enemies were perpetually on the watch for opportunities to check his power, and to introduce rivals who might, by the appearance of more liberality, depreciate his reputation and influence in the ſtate. During his abſence in Africa his enemies were ever on the alert to injure his fair fame, and to aſcribe unworthy and baſe motives to all that he did or propoſed to do; and in the tumult which accompanied the diſcuſſion of ſome of his laws after his return, he fled to the temple of Diana, and, unwilling to ſacrifice either himſelf or his adherents to popular fury, he propoſed terms of accommodation. Theſe were rejected by the arts of Opimius the conſul, and a price was inſtantly ſet upon the heads of Gracchus and his friend Fulvius. A formal battle enſued, in which multitudes were ſlain on both ſides, and the populace without heſitation deſerted their friends: Fulvius concealed himſelf, but, being diſcovered, was inſtantly killed. Gracchus, having ſolemnly imprecated upon the heads of the Roman people perpetual ſlavery for the baſe deſertion of the cauſe, left the city and paſſed acroſs the bridge named Sublicius. His retreat was favoured by two faithful friends, who defended the bridge till they fell covered with wounds. In the mean time Gracchus reached a grove ſacred to the furies, where it is ſaid a ſlave, by his order, firſt diſpatched him, and then put an end to his own life. Others have, however, given a different account of the matter; they ſay that he was overtaken by his enemies, and by them ſlain. His head was cut off and ſold to the conſul for its weight in gold. The body was thrown into the Tyber, but afterwards being taken from the water it was delivered to his afflicted mother for burial. This cataſtrophe, in which three thouſand perſons periſhed, happened in the year 121 B.C., and the ſenate immediately proceeded to aboliſh all the laws of the Gracchi. Their names, however, were ſtill fondly cheriſhed by the people, ſtatues were erected to their memory, and the places in which they were killed were conſecrated, by religious rites, to their manes. Caius has been generally conſidered as leſs pure in his intentions, and leſs moderate in his plans, than Tiberius. From the evidence of hiſtory it ſhould ſeem, that the diſturbance of the public tranquillity was rather owing to his oppoſers than to him; "ſo that," ſays the hiſtorian, "inſtead of calling the tumults of that period the "ſedition of the Gracchi," we ſhould rather call them the ſedition of the ſenate againſt the Gracchi, ſince the efforts of the latter were made in vindication of a law, to which the ſenate had aſſented, and as the deſigns of the former were ſupported by an armed power from the country that had never before interfered in the buſineſs of legiſlation, and the introduction of which gave a moſt irrecoverable blow to the conſtitution. Caius in his perſon was graceful, his action was ſtrong and impreſſive, his voice of great compaſs and melodious when the vehemence of his pleading did not raiſe it to too high a key; to correct this defect he was accuſtomed to place a judicious perſon behind him with a pitch-pipe, by which he was enabled to regulate his tone. In temper he was warmer than Tiberius, nor was he diſtinguiſhed by ſobriety of manners, though in this reſpect he might be advantageouſly compared to the Roman youth in general. Plutarch. Univer. Hiſt.

GRACE, Gratia, χαρις, in *Theology*, denotes in general any gift or favour, which God *freely* beſtows upon mankind; whether ſuch gift pertains to the preſent or future life: but as thoſe which relate to the improvement of their temper, and their fitneſs for final happineſs, were favours of the greateſt importance, this term is by way of eminence applied to them. The proper ſignification of the word *grace* is favour;—favour in ſuch a ſenſe as denotes mercy and goodneſs in a ſuperior, either remitting ſomewhat of his own right, or conferring ſomewhat beneficial upon others, *freely* and without any obligation of debt. And becauſe this may be done in various modes and in a great diverſity of inſtances, hence the word *grace* in ſcripture is accordingly applied in a correſponding diverſity of ſignifications. Sometimes it ſignifies thoſe extraordinary gifts and favours of the Holy Ghoſt, by which the apoſtles were enabled to demonſtrate the truth of their commiſſion, to preach their doctrines with authority, to convince gainſayers with evidence, and to govern the churches by a proper diſtribution of different truſts and offices. The gifts or powers, by which the apoſtles were enabled to do all theſe things with extraordinary efficacy and ſucceſs, are therefore called grace, becauſe they are not at all natural acquiſitions but free gifts of God; diſtributed to every one, not according to the will of man, but at ſuch times, and in ſuch proportions, and to ſuch perſons, and for ſuch purpoſes as God himſelf pleaſed. See Rom. i. 5. Epheſ. iv. 7. 11.

In other paſſages, the ſame word is uſed to ſignify that extraordinary aſſiſtance and ſupport which God has been pleaſed ſometimes to afford to his ſervants under extraordinary difficulties and trials; and this is called grace, becauſe it is conſidered as given particularly and gratuitouſly upon extraordinary occaſions over and above the general ſupports ariſing from the conſiderations of reaſon, and from the promiſes and motives of the goſpel in general. See 2 Cor. xii. 9.

A third ſenſe, in which the word grace ſometimes occurs in the New Teſtament, is to expreſs ſuch moral virtues as are the effects of men's being influenced by the ſpiritual motives of the goſpel, and the practice of which preſerves men in the favour of God, and recommends them to his gracious acceptance. (See Epheſ. iv. 29. 2 Pet. iii. 18. 2 Cor. viii. 1. 6.) Moral virtues are plainly for this reaſon diſtinguiſhed by the denomination of grace, becauſe they proceed from and are founded on a regard to God in general, and in particular to his will revealed under the gracious diſpenſation of the goſpel of Chriſt.

Another ſignification of the word grace in Scripture is to expreſs the merciful acceptance of repentance and amendment, by which God is pleaſed, not out of any obligation of juſtice, but in gracious goodneſs, to reſtore men to favour. In this ſenſe Paul ſays (1 Cor. xv. 9.) "By the *grace* of God I am what I am:" ſo John, i. 17., the doctrine of Chriſt is ſtyled "grace and truth." The Apoſtles' preaching is by St. Luke (Acts, xiv. 3.) called "the word," or declaration "of God's grace:" ſo when St. Paul declares (Rom. iii. 24.) that repenting ſinners are "juſtified freely by grace," and blames thoſe "who continue in ſin, that grace may abound." The word grace in all theſe paſſages ſignifies that merciful and compaſſionate diſpoſition of the divine nature, by which God freely remits of his right of puniſhment, and receives penitent ſinners, upon more gracious terms, and to greater degree of his favour, than he was bound to do by any obligations of juſtice.

Hence it is, that the goſpel itſelf, as being the great and ſtanding declaration of God's mercy and goodneſs towards men, ſhewn forth in the free pardon and forgiveneſs of ſin upon the gracious terms of repentance and amendment, is in the New Teſtament very frequently meant by the phraſe, "the grace of God." (Clarke's Serm. vol. ii. p. 265—275. 8vo. fol. ed. vol. i. p. 180, &c.) Biſhop Pearce (Comm. vol. ii. p. 259.) renders χαριτι in 1 Cor. x. 30. thankſgiving, and not grace, as it is in our verſion; and he obſerves that this ſenſe of the word χαρις is too frequent in St. Paul's writings to require a proof of it. He adds that ευχαριστω in the latter part of the verſe confirms this ſenſe.

Some divines define grace to be any degree of divine influence on the mind, inclining it to believe in Chriſt, and to practiſe virtue; and thoſe divine influences, which are not effectual in producing ſaving faith and ſincere obedience, they call *common* grace, in contradiſtinction to *ſpecial* grace, the operation of which is completely efficient and ſaving; and thoſe influences which introduce *ſpecial* grace, though they do not actually amount to it, are with reſpect to that introduction ſometimes called *preparatory*. It is diſputed among theologians whether ſpecial grace, which they ſuppoſe is never on the whole finally rejected, ſo as to fail of working faith in thoſe who are the happy objects of it, be in the nature of its operations upon the human mind *irreſiſtible* or not; and it is alſo queſtioned, whether common grace be *ſufficient*. Whether the mind be entirely *paſſive* in the firſt moment of its converſion, or whether there be any cooperation of our own together with the influences of divine grace upon the heart, is a queſtion, which has been alſo very much diſputed amongſt divines of a particular deſcription; and another queſtion, no leſs the ſubject of controverſy, is ſimilar to the former, and that is, whether the work of regeneration and converſion be accompliſhed in an *inſtant*. But we ſhould far exceed our preſcribed limits if we were to ſtate the arguments *pro* and *con* on queſtions of this nature.

Grace, in *Law*, is ſometimes uſed for a faculty, licence, or diſpenſation; but this ſeemeth to be only in a caſe where the matter proceedeth, as it were, *ex gratia*, of grace and favour; and not where the licence or diſpenſation is granted of courſe or of neceſſity.

Grace is alſo a term in the formula of all patents, &c. which begin, George, by the grace of God, king of Great Britain, &c. The Romiſh biſhops frequently began their mandates in the like manner: ſuch a one, by the grace of God, and the holy ſee, biſhop of, &c.

The Engliſh archbiſhops ſay, by divine grace, or divine providence. See Archbishop.

All ſovereigns uſe the phraſe grace of God; as emperors, kings, princes, &c. Anciently dukes, counts, and even lords, talked in the ſame ſtyle. In the new collection of Father Martene we meet with a mere ſeigneur, or lord, qualified by the grace of God ſeigneur de Comborn. Louis XI. forbade the duke of Britanny to ſtyle himſelf by the grace of God.

Grace is alſo a title of dignity, attributed to princes of inferior rank, and who are not qualified for that of highneſs.

In former times the kings of England were addreſſed under the title of grace, as they are now under that of majeſty. See King.

Our Engliſh dukes and archbiſhops are ſtill addreſſed under the title of grace. But that title is moſt frequent in Upper Germany, and particularly Auſtria, where it is borne by the barons, as being inferior to that of excellence.

Grace is alſo applied to perſons, and various kinds of performances, to denote a quality, or rather the reſult of a combination of qualities, which attracts peculiar notice, and affords peculiar pleaſure.

Grace is alſo uſed for a ſhort prayer offered before and after meat. This practice is very ancient, and has very generally obtained both in the heathen and Chriſtian world: and hence grace-cup is uſed by ſome of our poets for the cup or health drank after grace.

Grace, in the arts of *Painting* and *Sculpture*, is uſed to ſignify a peculiar quality which heightens the effect that beauty of form is calculated to produce, and renders it ſtill more engaging.

We have already, in the article Beauty, ſlightly touched upon this ſubject, and there mentioned the origin of the term among the Greeks; who gave to the Charites or Graces, whom they deified, the preſidency over whatever was amiable and engaging in the actions or ſentiments of mankind. By the undiſguiſed nakedneſs in which they always repreſented theſe goddeſſes, to whom they gave the names of Aglaia, Thalia, and Euphroſyne: they allegorized the pure ſincerity and ſimplicity in which acts of kindneſs ſhould always be wrought. By the union of theſe perſons, which are gently holding each other by the hands, or with their arms round each other's necks, they marked the union of ſpirit which dictates acts of benevolence and ſocial intercourſe; and by devoting them to the ſervice of Venus, exemplified the neceſſity of uniting the virtues of humanity to the beauties of perſon, in order to become truly engaging.

This allegory of the ancient Greeks leads us to the juſt conception of the meaning of the word grace when applied to the arts. Whatever can lend to beauty, increaſe of intereſt upon the beholder, is entitled to be called graceful, or at leaſt elegant. (See Elegance, in *Painting*.) As the heart of man, when inclined to good, is to his mental, ſo is grace to his perſonal accompliſhments; that, which gives the moſt delightful gratification to thoſe with whom he aſſociates. Without it, art is nothing, compared with the values it acquires by its preſence. Independent of all which conſtitutes mere beauty of form, it is abſolutely neceſſary to give it its full force, its greateſt effect, *viz.* that which beauty acquires by motion, wherein alone grace is viſible.

Poets as well as painters and ſculptors acknowledge the value of this quality: and the beſt have conſtantly applied it to the objects of their adulation when moving. Milton ſays of Eve, "Grace was in all her ſteps." Arioſto adds it to perfect the beauties of his Alvina; when he ſays,

> "Avea in ogni parte un laſcio teſe
> O parli, o rida, o canti, *o paſſo mova.*"

The graces, lurking about the mouth and the eyes of a beautiful perſon when in motion, are the moſt conſtant theme of poets, and as conſtantly the ſource of emulation to the painter and ſculptor to imitate; and when the artiſt has by his ingenuity diſcovered and repreſented truly thoſe minute variations of form which take place both in figure and features, when the mind is excited by ſome amiable emotion; he has obtained the ultimatum of his art; no power can go beyond it. Apelles, the ancient Greek artiſt of moſt repute, declared of his contemporaries, that their ſeveral works poſſeſſed every beauty but the perfection which grace alone can give: in this he found himſelf unrivalled. Ancient ſculpture is fraught with it; their figures, whether in action or repoſe, poſſeſs it; and when we ſay that it may be found in figures repoſing, we do not militate againſt the ſentiment that action is the baſis of grace; a previous motion being ſuppoſed to have taken place, to produce the graceful poſition. No figure, ſtanding, ſitting, or lying down, can be graceful, however beautiful it may be, whoſe parts or members are preſented altogether ſtraight and full to the eye. Without ſome varying turn being given to the head, the body, the arms, or the legs, it will be in vain to look for grace; and it is their being arreſted in the action they may aſſume, at the moſt agreeable and expreſſive point of view, which gives the conſummation of this invaluable quality to them. Then, if fixed for ever, they will be for ever graceful; and the delight which the contemplation of their mere beauty of form and proportion conveyed, will be heightened to the ſummit of that gratification which art is enabled to afford.

Wherein then lies this ſource of perfection? How, with certainty, may we expreſs it in our works? is the hitherto unanſwered query of the artiſt; or anſwered but in part and unſatisfactorily. All writers on painting have touched upon grace, and ſome have attempted to give information of the principles whereon it reſts. Lamozzo, in his Trattato della Pittura ſays, that Michael Angelo gave the following precept to Marcus de Sirena, his pupil. "That he ſhould always make a figure pyramidal, ſerpent-like, and multiplied by one, two, three!" In which precept (Lamozzo continues) in mine opinion the whole myſtery of the art conſiſteth. For the greateſt grace and life a picture can have, is, that it expreſs motion. Now there is no form ſo fit to expreſs *motion as that of flame of fire.*" This text is again repeated by Du Freſnoy, and thus has Dryden tranſlated the paſſage; "Large flowing gliding out-lines, which are in waves, give not only a grace to the part, but to the whole body, as we ſee in the Antinous, and in many other of the antique figures. A fine figure, and its parts, ought always to have a *ſerpent-like* and *flaming form;* naturally, thoſe ſorts of lines have I know not what of life and ſeeming motion in them; which very much reſemble the activity of the flame and of the ſerpent."

On theſe two remarks our own induſtrious and ſkilful Hogarth has built a ſyſtem, which, if it be not altogether compleat, has yet much ſagacity and utility in it, and which he has given to the world in his Analyſis of Beauty. He therein adopts the ſerpentine line, (which he illuſtrates by ſuppoſing a wire drawn ſpirally round a cone from its baſe to its apex), as the baſis of grace, with much apparent truth: and he is moſt certainly ſupported by all thoſe fine works wherein gracefulneſs is acknowledged to reſide. The Torſo of the Belvidere, the Venus de Medicis, the Apollo Belvidere, the Laocoon, who, in the midſt of the violent anguiſh he ſuffers, ſtill poſſeſſes grace. All theſe, and indeed all others, which have any pretenſions of the like kind, have the ſerpentine line for the baſe of their compoſition, in a greater or leſs degree. Who ſhall laugh at a ſyſtem upheld by ſuch authority! Walpole attempts to ridicule it, as well as others, becauſe Hogarth was not equal to put it in practice. The futility of ſuch an argument needs no illuſtration. To conceive a thing in the imagination, and not be able to exemplify it by practice, is by no means an uncommon occurrence among artiſts, or among men; yet the propriety of the conception may be unqueſtionable, taken on general grounds. Hogarth's miſtake appears to have been, having fixed the boundary of grace; having given what he calls the *preciſe line* of it; whereas, all the antique figures mentioned above are graceful, while each varies from the other in the quantum of curve which its action conſiſts of. Hence ariſes, that he ſo narrowed the ſphere wherein grace was obſervable, which in nature is found to be ſo widely extended, that, without juſt conſideration, his ingenuity was regarded as the ravings of excentricity; whilſt no good arguments were adduced to diſprove the general principle, which appears to us to be juſt. How to employ it, is another queſtion. And here we fear no rules will ſuffice to guide the practitioner in art. As we ſaid of elegance, we repeat of grace: he that is endowed by nature with a power to feel its beauties, and diſplay its effects, may, by cultivation, improve his original ſtock; but he that requires to be taught what grace is, will, in vain, ſeek to obtain the power of painting it; if he ever arrives at the knowledge of it, or the power of ſeeing it, in nature or in art. A conſtant obſervation upon the actions, in figure and feature, of thoſe who are by nature graceful, is the beſt ſchool in which to ſtudy it, and the readieſt mode to diſcover wherein it lies.

Grace is not, or rather ought not, to be confined to the figures in a compoſition. Every part of the picture ſhould have a conjunctive effect to produce grace in the whole. Contraſt of form will aid the beauty of the principal parts, but that contraſt ſhould never force itſelf into notice, the artifice would then become apparent, and the eye would not be led to the beautiful parts, but, on the contrary, be detained from them. The painter therefore who has conceived a graceful figure, ſhould either paint it ſingly, or be careful ſo to ſupport it, by proper accompanying lines and objects, that its beauty be not loſt in the maſs, and its effect overpowered by other forms of leſs value becoming obtruſive to the obſerver. And great care ſhould be taken to prevent every attempt to produce grace in the action of figures, from degenerating into affectation. Where that begins, grace ends: and deteſtation or ridicule, inſtead of admiration, becomes the meed of the artiſt! No vice in art is ſo odious as affectation! If the beſt executed work imaginable be unhappily tinctured with it, few minds of an elegant or graceful turn of feeling will bear to dwell upon it. Thoſe artiſts who allow their minds to be impreſſed with the paſſion or ſenſation they wiſh to convey in their figures, and thence conceive the action of them, are not ſo liable to fall into this error, as thoſe whoſe ideas are more intent on making an agreeable picture, and think of the actions, before they have conſidered the paſſions of their figures. Raphael is an inſtance of the former; Correggio and Parmigiano, great and graceful as they frequently were, nevertheleſs belong too often to the latter claſs, and even their extraordinary brilliancy of talent does not ſecure them from juſt cenſure when that is the caſe.

The beſt examples of grace are to be found in ancient ſculpture and paintings, and in the works of Raphael. Some few of the works of Correggio, of Parmigiano, and of Guido Rheni, poſſeſs it, perhaps, more refined than Raphael's; but they are ſo near the extreme boundary wherein real unaffected grace reſides, that they are dangerous exemplars to a ſtudent. A confirmed artiſt may obſerve them to advantage.

Sir Joſhua Reynolds poſſeſſed it largely, and perhaps we ought to have added his name to Raphael's. But yet he is not always pure: a little too much of the Correggieſque is admitted in ſome of his fancy pictures; and particularly in the expreſſions of the features.

GRACE, *Act of*, properly denotes an act of amneſty, or oblivion, for the pardon of all offenders who are qualified, or come within the conditions of it.

The term is alſo ſometimes extended to an act made for relief of inſolvent debtors in the ſeveral priſons; by ſetting thoſe who are qualified, at liberty from their debts and confinement.

GRACE, *Covenant of*. See COVENANT.

GRACE *Cup*, ſo called becauſe the beverage contained in it was circulated amongſt the community, or other company, at a particular time, and by a ſpecial favour. It was alſo called *Poculum Charitatis*, or the *Cup of Charity*, as being intended to indicate and promote brotherly love. At other times it was termed the *Waſſel Cup* or *Bowl*, becauſe each one of the company, in drinking out of it, drank health to his next neighbour in the old terms, *Was heil*. William of Malmeſbury, deſcribing the cuſtoms of Glaſtonbury abbey ſoon after the conqueſt, ſays, that on ſuch and ſuch particular days, the monks had "Medonem in juſtis et vinum in charitatem:" Mead in their cans, and wine in the grace cup. A large cup or bowl of this nature was always heretofore placed on the table of princes, &c. as well as of abbots. In the eleventh volume of the Archæologia there is an engraving of a grace cup, which formerly belonged to Glaſtonbury abbey, and a diſſertation upon it by Dr. Milner. The inſide of this cup, which holds two quarts, is furniſhed with eight pegs, at equal diſtances, one below the other, in conformity with Edgar's law, to repreſs exceſs in drinking. This meaſurement allowed of half a pint to each perſon.

GRACE, *Days of*. See DAY, in *Law* and *Commerce*.

GRACE, *Herb of*. See RUE.

GRACES, GRATIÆ, in the *Canon Law*, are the ſame with what we otherwiſe call *proviſions*; which ſee.

GRACES, *Expectative, Gratiæ Expectativæ*. See EXPECTATIVE.

GRACES, *Gratiæ, Charities*, in the *Heathen Theology*, were fabulous deities, three in number, who attended on Venus.

Their names are Aglaia or Eglé, Thalia, and Euphroſyne; *i. e.* ſhining, flouriſhing, and gay; and they were ſuppoſed by ſome to be the daughters of Jupiter and Eurynome, the daughter of Oceanus, and by others to be the daughters of Bacchus and Venus. Voſſius de Idol. lib. xiii. cap. 15. Homer (Iliad, lib. xiv.) changes the name of one of the graces, and calls her Paſithée, and he is followed by Statius. (Theb. lib. ii.)

Some will have the graces to have been four, and make them the ſame with the *Horæ*, *Hours*, or rather with the four ſeaſons of the year. See HOURS.

The Lacedæmonians admitted only two of them, whom they worſhipped under the names of Clito and Phaenné. The Athenians allowed the ſame number, but denominated them Auxo and Hegemone.

A marble in the king of Pruſſia's cabinet repreſents the three graces in the uſual manner, with a fourth, ſeated, and covered with a large veil, with the words underneath, AD SORORES IIII. Yet Monſ. Beger will by no means allow the graces to have been four: the company there preſent, he underſtands to be the three graces, and Venus, who was their ſiſter, as being daughter of Jupiter and Dione.

They are always ſuppoſed to have hold of each other's hands, and never parted. Thus Horace, (lib. iii. od. 21.) deſcribes them:

> "Segneſque nodum ſolvere gratiæ."

They were alſo repreſented in the attitude of perſons dancing; whence Horace ſays (lib. i. od. 4.):

> "Alterno terram quatiunt pede."

They were commonly thought to be young virgins. In the earlier ages they were repreſented only by mere ſtones, that were not cut; but they afterwards were repreſented under human figures, at firſt clad in gauze. But the cuſtom of giving them drapery was laid aſide; and they were painted naked to ſhew that the Graces borrow nothing from art, and that they have no other beauties than what are natural.

Yet, in the firſt ages, they were not repreſented naked, as appears from Pauſanias, lib. vi. and lib. ix. who deſcribes their temple and ſtatues. They were of wood, all but their head, feet, and hands, which were white marble. Their robe or gown was gilt; one of them held in her hand a roſe, another a die, and the third a ſprig of myrtle.

They had temples, as we learn from Pauſanias, at Elis, Delphos, Perga, Perinthus, Byzantium, and in ſeveral other places of Greece and Thrace. The temples conſecrated to Cupid were alſo conſecrated to the Graces: and it was alſo cuſtomary to give them a place in thoſe of Mercury, in order to teach men, that even the god of eloquence needed their aſſiſtance. Indeed ſome authors reckoned the goddeſs of perſuaſion in the number of the Graces, thus intimating, that the great ſecret of perſuaſion is to pleaſe. The Muſes and the Graces had commonly but one temple; and Pindar invokes the Graces almoſt as often as he does the Muſes. Feſtivals were appropriated to their honour through the whole courſe of the year, but the ſpring was chiefly conſecrated to them as well as to Venus. Greece abounded with monuments ſacred to theſe goddeſſes; and their figures were to be ſeen in moſt cities, done by the greateſt maſters. They were alſo repreſented on many medals. The favours which theſe goddeſſes were thought to diſpenſe to mankind, were not only a good grace, gaiety, and equality of temper, but alſo liberality, eloquence, and wiſdom, as Pindar informs us; but the moſt noble of all the prerogatives of the Graces was, that they preſided over all kindneſſes and gratitude; inſomuch that, in almoſt all languages, their names are uſed to expreſs both gratitude and favours.

GRACES. There is a good article for Fr. muſic, by M. Framery, under the term *Agrémens*, New Encycl. Meth. p. 54: in this he candidly acknowledges all the defects aſcribed to Fr. ſinging by Rouſſeau and Burney. See AGRÉMENS, RIFIORAMENTI, SHAKE, BEAT, TRILL, and *Muſical* CHARACTERS.

GRACIAN, BALTHASAR, in *Biography*, an eminent Spaniſh writer, was born in 1603. He entered among the Jeſuits at the age of ſixteen, and became a teacher in their ſociety;

ſociety, of the belles-lettres, of philoſophy, and of theology. He likewiſe exerciſed the duties of a preacher, and was at length rector of the Jeſuits' college of Tarragona, where he died in the year 1658. He was a much eſteemed author, and moſt of his works have been tranſlated into French and other foreign languages. The principal of theſe are "The Hero;" "Reflections on the political Conduct of Ferdinand the Catholic;" "A Treatiſe on the different Kinds of witty Conceptions." A work treating of the errors to which man is liable, and a collection of meditations on taking the holy communion. Moreri.

GRACIAS A' DIOS, in *Geography*, a town of Mexico, in the province of Honduras, and audience of Guatimala, ſituated at the mouth of a river, which communicates with the bay of Honduras. It has ſome gold mines in its neighbourhood. N. lat. 14° 30'. W. long. 90° 6'—Alſo, a cape on the N. coaſt diſcovered by Columbus. N. lat. 15°. E. long. 132° 50'.—Alſo, a cape, called "Falſe Cape Gracias a' Dios," on the coaſt of Nicaragua, 63 miles from the other. N. lat. 13° 36'.

GRACILIS, in *Anatomy*, a muſcle of the leg, thus called from its ſlender ſhape.

It ariſes partly tendinous, and partly fleſhy, from the os pubis internally, between the firſt and ſecond heads of the triceps; and in its deſcent on the inſide of the thigh, grows narrow, and becomes tendinous, a little below the ſartorius, and is thus inſerted into the tibia. It aſſiſts in bringing the thigh and leg inwards.

GRACILIS *Rectus*, a name given by Riolan to one of the muſcles of the leg, called by Winſlow the rectus cruris anterior, and by Cowper the rectus femoris. Albinus calls it the rectus cruris.

GRACULA, in *Ornithology*, a genus of the order Picæ, having the bill convex and acute at the edges, the baſe rather naked: tongue entire, ſharpiſh, and fleſhy; and the feet formed for walking. The genus gracula correſponds with the mainate of Briſſon, from whom it appears to have been adopted by Linnæus under the former term. Some of the ſpecies of this natural tribe were known to Ray, who refers them to the crows; and alſo to Willughby, who conſiders them as of the ſtare or ſtarling kind. The ſpecies of gracula, deſcribed in the Gmelinian Syſtema Naturæ, amount to twelve; and this number is increaſed to fourteen in the work entitled "Index Ornithologicus" of Dr. Latham, by the addition of the new ſpecies *icterops*, and the introduction of the Linnæan *Paradiſea triſtis*, which latter the laſt mentioned writer has deemed it requiſite to remove to this place. As a ſecondary to the eſſential or generic character above deſcribed, it may be proper to obſerve that the birds of this kind have the bill thick, and compreſſed at the ſides; the noſtrils ſmall, at the baſe of the bill and ſometimes ſituated near the edge; the toes three forward and one behind, the middle toe connected at the baſe to the outer one, and the claws hooked and ſharp. Their principal food conſiſts of fruits and inſects.

Species.

RELIGIOSA. Violet-black; ſpot on the wing white; band on the hind head naked and yellow. Gmel. Linn. *Mainatus*, Briſſ. *Sturnus indicus Bontii*, Ray. *Bontius's Indian ſtare*, Will. *Le Mainate*, Buff. *Minor grakle*, Albin.

The length of this bird is ten inches and a half, its bulk equal to that of the black-bird: the bill an inch and a half long, of an orange colour tipped with yellow; the legs tawny or orange; feathers of the head, except the middle ones, very ſhort and ſilky; and the naked band reaching nearly to the nape. This ſpecies is found in many parts of India, and not unfrequently in a tame or domeſticated ſtate, being naturally of a familiar diſpoſition, and capable of being taught to whiſtle, ſing, and imitate the articulations of the human voice with greater preciſion than any of the parrot tribe. In the iſlands of Sumatra and Java it is called by the natives *hill-maynoa*, and in China, whither it is imported from the latter place, its common name is Teeong. Several ſuppoſed varieties of this bird are deſcribed by writers, the moſt remarkable of which is that called the greater minor grakle, le grand mainate of Briſſon; this entirely correſponds with the ordinary kind, except in ſize, which it materially exceeds, being in this reſpect not inferior to the jackdaw; it inhabits the iſland of Hainan, in Aſia.

CALVA.—Sub-cinereous, with the head naked each ſide. Linn. *Merula calva Philippinenſis*, Briſſ. *Merle chauve des Philippines*, Buff. *Goulin*, ib. *Iting, Tabaduru, vel Gulin*, &c. Phil. Tranſ. *Bald grakle*, Lath.

Size of the black-bird, with the head and cheeks bare of feathers and fleſh-coloured, except a narrow liſt of ſhort brown feathers, extending from the baſe of the bill to the back of the head; the naked part becoming of a deep red when the bird is irritated: the general colour above is ſilvery-aſh, beneath grey-brown, bill and legs brown. Theſe birds build their neſt in the hollows of trees, eſpecially preferring thoſe of the cocoa-nut: it is repreſented as a noiſy chattering bird, of voracious appetite, and as living principally on fruit. Found in the Philippine iſlands.

FŒTIDA. Black; exterior part of the quill-feathers blueiſh; band round the neck naked. Linn.

Native of America, in ſize reſembling the magpie: the head with erect, ſhort, ſilky feathers; noſtrils oval and naked; tongue ſharp; and tail even at the tip.

BARITA. Somewhat grey; ſhoulders blue; quill-feathers at the outer edge green. Linn. *Monedula tota nigra*, Ray. *Boat-tailed grakle*, Lath.

Size of the cuckow: the bill ſhortiſh, rather black, paler beneath and naked at the baſe; the plumage black, inclining to grey, and gloſſed with purple; tail rounded, concave when folded, and becoming flat on being expanded; legs and claws black. The ſpecies inhabits the Antilly iſlands and North America. It feeds on inſects and fruits.

CRITATELLA. Black, the firſt quill-feathers at the baſe, and tail-feathers at the tip white; bill yellow. Gmel. *Merula ſinenſis criſtata*, Briſſ. *Merle huppé de la Chine*, Buff. *Chineſe ſtarling or black-bird*, Edwards.

A ſpecies rather larger than the black-bird; the plumage inclining to blue, with a creſt of feathers on the head which it can raiſe and depreſs at pleaſure; greater quill-feathers from the baſe to the middle white, the remaining part deep blue; tail-feathers, except the two in the middle, tipped with white; legs dull yellow. The creſted grakle ſings and talks like the ſpecies religioſa, but with inferior diſtinctneſs; and is frequently kept in cages in China, which country it inhabits in a wild ſtate; its principal food is rice, worms, and inſects.

SAULARIS. Blueiſh-black; belly, ſpot on the wings, and lateral tail-feathers white. Gmel. *Lanius bengalenſis niger*, Briſſ. *Pie grieſche noir de Bengale*, Buff. *Bengal magpie or dial-bird*, Albin. *Dial grakle.*

Native of Bengal. Size of the Miſſel thruſh, with the head, neck, breaſt, back, rump and upper tail-coverts black; belly, ſides, thighs, and under tail-coverts white; tail even at the end, black above, and white beneath. The female differs in being black inſtead of brown on the fore-part of the neck and breaſt, and in the white being more obſcure.

QUISCALA. Violet, black; tail rounded. Linn. *Picus jamaicenſis*, Briſſ. *Cornix purpurea*, Klein. *Fur-zeæ*, Kalm. *Izanatl*, Ray. *Black-bird, or maize-thief*, Kalm. Tr. *Purple grakle*, Arct. Zool.

Native of Mexico, and the warmer parts of America, and the Weſt Indies; ſings finely, builds on trees, is deſtructive to plantations, but uſeful in deſtroying the noxious inſects that infeſt them. The fleſh is black and unſavoury. Its ſize is about that of the black-bird, the male a little exceeding the female in bulk; the bill and legs are black; tail long and cuneated, and with the wings purple; the female entirely duſky.

ATTHIS. Greeniſh-blue; belly ruſty; legs blood-red, Linn. *Corvus Ægyptius*, Haſſelq. *Egyptian grakle*, Lath.

Size of a lark; and is ſuppoſed by Haſſelquiſt to feed on inſects, the remains of centipedes and ſcorpions being found in the ſtomach. The bill is black; neck with a longitudinal ruſty line each ſide, and the claws black.

LONGIROSTRA. Brown, beneath ochre-yellow; head and neck black; band round the neck naked and wrinkled; area of the wings white; tail cuneated, black, and at the tip white. Pallas, &c.

Native of South America; length eight inches. This appears to be the ſame ſpecies as that deſcribed by Sonnini under the name of merle des Savannes.

STURNINA. Hoary; ſpot on the crown and back between the wings violet-black; tail and wings with a tinge of green, the latter with a double white ſtripe. Pallas.

Inhabits the Ozier banks of Dauuria; the neſt and eggs reſemble thoſe of the thruſh; the plumage of the female is dirty aſh, with the back brown; and the wings and tail deep black.

ICTEROPS. Black; band on the wings and body beneath white; the region of the eyes naked and wrinkled. Lath. *Le mainate a face jaune*, Vieill. *Yellow faced grakle.*

Length ſeven inches and a half; bill compreſſed; noſtrils oval; legs yellow and wrinkled. Native of New Holland.

CAYANENSIS. Striated; above tawny, beneath yellowiſh; head and chin varied with tawny and white; tail wedged, ſharp and with the wings tawny. Gmel. *Climbing grakle.*

Inhabits the interior parts of Guiana; is about ten inches in length, and remarkable for climbing trees; the bill is black, about two inches long, and a little curved; the legs are alſo black.

CARUNCULATA. Cinereous; tail and quill-feathers black; crown and chin with warty excreſcences. Gmel.

Length ſix inches; and ſuppoſed to inhabit the Cape of Good Hope.

MELANOCEPHALA. Head black, front white; back, tail, and wing-coverts blueiſh-aſh, the laſt with a tranſverſe white ſtreak near the extremity. Don. *Gracula melanocephala*, Lath. *Le mainate a tête noire*, Vieill. *Black-headed grakle.*

A ſpecies recently diſcovered in New South Wales; its height is about eight inches; the bill yellow, a little bent, and formed at the baſe like that of the *Turdus*, or thruſh tribe; the tail three inches long; the legs very long in proportion, of a pale yellow ochre-colour, and armed with ſtrong blackiſh claws.

VIRIDIS. Dull green; throat above brown and blackiſh varied; under parts of the plumage whitiſh, with ſome blackiſh ſtreaks; wings blackiſh, edged with white; tail blackiſh, with white tip. Don. *Gracula viridis*, Lath. *Le mainate vert*, Vieill. *Green grakle.*

Lately found; the ſpecies inhabits New Holland, and appears to be very rare; the bill is ſtrong, ſomewhat inclining at the baſe, and the colour of horn; the legs blackiſh.

CYANOTIS. Space about the eyes bare of feathers and bright blue; head black, with a white croſs on the hind part; upper part of the neck, body, ſcapulars, wing-coverts, and tail yellowiſh-green; breaſt lead-colour; plumage beneath white. Don. *Gracula cyanotis*, Lath. *Le mainate a oreilles bleues*, Vieill. *Blue eared grakle.*

Length twelve inches and a half; bill black; legs blue black, with very hooked black claws. Native of New South Wales.

PICATA. Greater part of the head, the neck; tranſverſe band on the breaſt, back, border of the wings, and tail above nearly to the tip black; throat, breaſt, wing-coverts, body beneath, and under ſurface of the tail-feathers white. Don. *Gracula picata*, Lath. *Le mainate pie*, Vieill. *Pie grakle.*

Rather larger than the black-headed grakle, and like that ſpecies inhabits the regions of Auſtralaſia; the general colour black and white, the former partially gloſſed with purple; bill yellow, and correſponding in form with that of the black-headed grakle; and the legs lead colour.

GRACULUS, the *Shagge*, a ſpecies of *Pelecanus*; which ſee.—Alſo, a ſpecies of *Corvus*; which ſee.

GRADATION, the act of aſcending, ſtep by ſtep, to any pitch or eminence: from the Latin *gradus*, *degree*, *ſtep*.

GRADATION, in *Architecture*, ſignifies an artful diſpoſition of parts, riſing, as it were, by ſteps or degrees, after the manner of an amphitheatre: ſo that thoſe placed before do no diſſervice, but rather ſervice, to thoſe behind.

The painters alſo uſe the word gradation for an inſenſible change of colour, by the diminution of the teints and ſhades. See below.

GRADATION, in *Chemiſtry*, is a kind of proceſs belonging to metals. It conſiſts in gradually raiſing, or exalting them to a higher degree of purity and goodneſs, ſo as to increaſe their weight, colour, conſiſtence, &c.

GRADATION, in *Logic*, is an argumentation, conſiſting of four or more propoſitions, ſo diſpoſed as that the attribute of the firſt is the ſubject of the ſecond; and the attribute of the ſecond is the ſubject of the third, and ſo on, till the laſt attribute come to be predicated of the ſubject of the firſt propoſition. As in Porphyry's tree; man is an animal; an animal is a living thing; a living thing is a body; a body is a ſubſtance; therefore man is a ſubſtance.

An argument of this kind is liable to many fallacies; both from the ambiguity of words and things; *e. gr.* Peter is a man; man is an animal; animal is a genus; genus is an univerſal; therefore Peter is an univerſal.

GRADATION, in *Painting*, relates both to chiaro-ſcuro and to colour: that is, all the different degrees in which light and dark, and colour may be modified, are comprehended in it.

An object receding from the light, and gradually loſing it, becomes at its fartheſt extremity obſcurely defined. A coloured body, pure or bright in teint, under the ſame circumſtances, gradually diminiſhes in clearneſs of hue throughout its receding parts, and becomes dull and dark. By fixing the ſcale of gradation in both theſe particulars, effects of great force or great ſimplicity may be produced. The ſcale of deſcent being made rapid, great force will enſue, from the ſtrong oppoſitions it promotes; and the reverſe will take place when the degrees of deſcent are prolonged, and leſs contraſt thereby effected. The nature of the ſubject, jeĉt, and the ſituation of the figures with regard to light, muſt's be the artiſt's guide in this matter.

The gradation of colour includes not only what is mentioned above, *viz.* the different degrees of purity, or brilliancy of the ſame colour, but alſo the approximations of each colour to its neighbour, neceſſary to produce harmony; and alſo the art of gradually loſing the local colour in obſcurity, and yet maintaining the character of it in the object: which is extremely difficult and of great importance in the art of painting.

Gradation, in *Rhetoric*, is when a ſeries of conſiderations or proofs is brought riſing by degrees, and improving each on the other. See Climax.

Such is that in Cicero to Herennius: "Africano induſtria virtutem, virtus gloriam, gloria æmulos comparavit."

GRADI, *Italian*, degrees. Every eccleſiaſtical mode, and every key in ſecular muſic, has its *gradus*, its ſcale; no note of which can be changed by an accidental *flat*, *ſharp*, or *natural*, without changing the key. As in the key of F major with one flat at the clef, annul that flat by a natural, and the key is changed to C, add another flat and it modulates into B♭.

GRADISCA, or Gradisch, in *Geography*, a town of Germany, and capital of a ſmall county, annexed with Goritz to the dominions of Auſtria, ſeated on the Lizonzo, built in the year 1473 to ſtop the incurſions of the Turks, additionally fortified in 1764, and erected into a biſhopric in 1784; taken by the French in 1797:—5 miles S. of Goritz. N. lat. 46° 2′. E. long. 13° 27′.—Alſo, a town of Sclavonia, on the river Save, near the borders of Croatia, well peopled and fortified; 132 miles W. of Belgrade. N. lat. 45° 10′. E. long. 17° 50′.

GRADISELLO, a town of Italy, in the department of the Adda and Oglia; 8 miles S. of Breno.

GRADISTA, a town of European Turkey, in Bulgaria, on the borders of Servia; 40 miles S. of Viddin

GRADISZTE, a town of Walachia; 48 miles N.E. of Galacz. N. lat. 45° 23′. E. long. 27° 19′.

GRADITZ, a town of Bohemia, in the circle of Konigingratz; burnt by Ziſca; 12 miles N. of Konigingratz.

GRADO, a ſmall iſland in the gulf of Venice, near the coaſt of Friuli, with a town which was the firſt ſee of the Venetian patriarch. N. lat. 45°. E. long. 13° 17′.

GRADUAL, Graduale, was anciently a church-book, containing divers prayers, rehearſed, or ſung, after the epiſtle: called in ſome of our ancient writers *gradile*, *graduale*, *graile*, &c.

After reading the epiſtle, the chantor aſcended the ambo with his gradual, and rehearſed the prayers, &c. therein; being anſwered by the choir; whence the name gradual, on account of the ſteps or degrees of the ambo.

The gradual or graile, which the provincial conſtitutions of archbiſhop Winchelſea, made at Merton, A. D. 1305, required to be in every church, was a book containing all that was to be ſung by the choir at high maſs; the tracts, ſequences, hallelujahs; the creed, offertory; triſagium, and alſo the office for ſprinkling the holy water. "Gradale ſic dictum, a gradalibus in tali libro contentis."

It is ſometimes taken for a maſs-book, or part of it, inſtituted by pope Celeſtine, anno 430. See ſtat. 37 Hen. VI. cap. 32.

In the Romiſh church, gradual is an appellation ſtill given to a verſe which they ſing after an epiſtle, and which was anciently rehearſed on the ſteps of the altar: though Ugutio gives us another account, and ſays it took its denomination gradual becauſe ſung in the gradual aſcent from note to note. Magri ſpeaks differently ſtill, and will have it to have taken its name becauſe ſung while the deacon went up the ſtairs to the pulpit, to ſing the Goſpel.

Gradual, *Gradualis*, is alſo applied to the fifteen pſalms, ſung among the Hebrews, on the fifteen ſteps of the temple. Others are rather of opinion that they were thus denominated becauſe the ſingers raiſed their voice by degrees, from the firſt to the laſt.

Cardinal Bona, in his treatiſe of Divine Pſalmody, ſays, the fifteen gradual pſalms are intended to repreſent to the mind, that we only arrive at the perfection of goodneſs, or holineſs, by degrees. He goes on to lay down the fifteen degrees of virtue, correſponding to the fifteen pſalms; five of them are for beginners; five for proficients; and the reſt for the perfect.

GRADUATE, a perſon who has the degrees of any faculty: a graduate in phyſic, in divinity, in muſic, &c. See Degree, Doctor, &c.

This privilege of graduates is no older than the fifteenth century: it being obſerved, that men of learning were much neglected by the collators, and patrons of churches; complaint, therefore, was made to the council of Baſil, where this decree was made; which was afterwards confirmed by the Pragmatic Sanction, and again by the Concordat.

GRADUATION *of Aſtronomical Inſtruments*, is the dividing of a circle, or of ſome aliquot part thereof, into degrees and its ſub-diviſions, on the limb of any inſtrument that is uſed for meaſuring angles with a great degree of accuracy. (See the article Degree.) When the inſtrument to be graduated is of a portable ſize, admitting of only a ſmall radius of curvature for the limb that is to be divided, the operation is very readily as well as accurately performed by an engine, ſuch as Ramſden's or Troughton's, the former of which we have deſcribed under the article Engine *for dividing Circles*, &c. but when the radius of the inſtrument is too large to admit of diviſion by an engine, the taſk of graduating, by the determination and adoption of original dividing points or lines, requires no ordinary portion of ſkill, manual dexterity, and perſeverance to be united. Before the eſtabliſhment of the Royal Obſervatory at Greenwich, the art of graduating was in a rude ſtate, but a deſire to have this inſtitution furniſhed with ſuperior inſtruments of obſervation has ſtimulated the different aſtronomers royal, ſucceſſively, to encourage the talents of ſuperior artiſts from time to time, till at length ſuch perfection is attained, that little more can now be hoped for in the improvement of our beſt Engliſh inſtruments. The hiſtory of the art of graduating aſtronomical inſtruments, and the gradual developement of the moſt convenient and moſt accurate modes of proceeding, together with the difficulties to be ſurmounted in the various ſtages of progreſs towards perfection, will be beſt explained by a conciſe detail of each ſucceſſive method of dividing, that has been practiſed, agreeably to the order of time; and by remarks ariſing out of each detail, as they moſt naturally occur.

We know not ſufficient of the aſtrolabes of Hipparchus and Ptolemy to enable us to give any ſatisfactory account of the nature and accuracy of their diviſions and ſub-diviſions, though it is probable that the graduated circles on them contained each 360°, agreeably to the Egyptian mode of dividing the circle. Neither can we give a very perfect deſcription of the manner in which Copernicus, long afterwards, had his aſtrolabe and meridian quadrant graduated, though we have ſhewn under our article CIRCLE that his parallactical inſtrument, with which his altitudes were chiefly taken, had its limb divided by equal diviſions that were the ſubtenſes of 3′ 49.″137 each.

Tycho Brahe's inſtruments had the advantage of a long radius, which rendered any inequalities that might occur in his diviſions of leſs value than they would have been in inſtruments of ſhort radii; the ſmalleſt ſub-diviſions into which he profeſſed to mark his ſpaces were 10′ each, and the ſingle minutes and portions of a minute, even to 15″ and 10″, were indicated by triangular diagonals; but with what degree of preciſion the ſub-diviſions were effected, and what dependence could be placed on his diagonals, as to accuracy, at this diſtance of time, it is not an eaſy matter to aſcertain: it is recorded, however, that the operation of graduating his inſtruments was performed by his own manual labour.

And what we have here ſaid of the inſtruments of Tycho Brahe, is equally true of the *machina cæleſtis* of Hevelius; whatever accuracy his apparatus poſſeſſed, was the reſult of his own perſevering induſtry, but we are not aware that his methods of proceeding have been particularly detailed.

In Dr. Hook's Animadverſions on the *Machina Cæleſtis* of Hevelius, 1674, this very ingenious mechaniſt has publiſhed an account of his method of racking the exterior edge of the limb of his quadrant, as performed by Tompion, which method, he ſays, "does not at all depend upon the care and diligence of the inſtrument-maker, in dividing, graving, or numbering the diviſions, for the ſame ſcrew makes it from end to end." But, as Smeaton has very properly obſerved, this inventive contriver has not given his reader any precautions or particular directions how the perfection of the ſcrew is to be enſured, or how the notches of the rack work are to be rendered perfectly equal among themſelves, notwithſtanding the unequal denſities, and hardneſs of different portions of the metal ſo racked. The difficulties alluded to here, were acknowledged by the duc de Chaulnes, in a memoir of the Royal Academy of Sciences at Paris, publiſhed in the year 1765. The doctor called the account of his method, "an explication of the new way of dividing," and as an original invention, it may probably be called his own, though the want of a perfect ſcrew, with intervals exactly proportioned to the effective radius of his quadrant, was a ſource of error, that poſterior contrivances were required to remedy. See ENGINE (by Ramſden) *for cutting the ſcrews of the circular dividing engine.*

The uſe of Dr. Hook's ſcrew for racking the limb of an aſtronomical inſtrument was not, however, abandoned, without a fair trial of its accuracy in reading the quantity of the angles ſo meaſured; for Flamſtead, (or Flamſteed,) on his appointment to the Royal Obſervatory in 1676, employed Tompion to conſtruct him a ſextant of ſix feet nine and a quarter inches radius, at the expence of Jonas Moore, with an endleſs ſcrew of ſeventeen threads per inch, acting on the racked edge of the limb, and with teleſcopic ſights, which had not been before uſed: the reſult of this trial was, that ſome ſhake took place in the notches, that were worn by the ſcrew, and frequently an error of a whole minute in reading an obſervation was unavoidably produced thereby. To remedy this evil, in the following year degree ſpaces, with diagonal diviſions to read to the accuracy of 10″, were added as a check on the meaſures of the ſcrew, and a column, to contain the *check* angle by diagonal lines, was filled up from the 11th of September of the year 1677. Theſe additions, it appears, from the *Prolegomena* of the *Hiſtoria Cæleſtis*, were inſerted by Flamſtead himſelf, and a compariſon of the ſcrew with the diagonals proved that an error of as much as *one minute* was frequently the reſult of the reading by the ſcrew. In an obſervation of the moon, taken on the 9th of June 1687, Smeaton ſays, that on looking over the obſervations, he detected an error of 55″, which, upon a radius of ſix feet nine inches, he calculates amounts to more than $\frac{1}{50}$th part of an inch. The ſcrew, however, was uſeful for giving a regular ſlow motion to the teleſcopic ſights, and though its uſe, as an accurate meaſure of a large arc, was ſoon abandoned in aſtronomical inſtruments, it has been retained as an excellent mode of producing a ſlow motion, by the aid of a tapped clamping piece, and has been applied with great ſucceſs to the limb of a dividing engine, which, being a complete circle, admits of equalization of the contiguous notches, by a long continued ſimultaneous action of ſeveral threads of a very perfect ſcrew, carried many times all round the circle, when the exact ſituations of diſtant notches have been enſured by the checks afforded by accurate diviſions, previouſly made on its plane.

Notwithſtanding what we have above ſaid of the imperfect meaſurement of an angle by the ſcrew, it was not relinquiſhed without another trial in Flamſtead's time, by Abraham Sharp, his amanuenſis, to whoſe ſkill and dexterity in manual operations of a mechanical nature both Flamſtead and Smeaton have borne ample teſtimony; the latter of whom ſays, "I look upon Mr. Sharp to have been the firſt perſon that cut accurate and delicate diviſions upon aſtronomical inſtruments." The inſtrument at which Sharp laboured, and to which he applied the ſcrew in conjunction with the diagonals of the divided ſpaces, in 1689, was the *mural arc* at Greenwich, of which the radius is ſix feet ſeven inches and a half. "But yet," ſays Smeaton, in his paper on this ſubject, read November 17, 1785, at the Royal Society's room, "whoever compares the different parts of the table for converſion of the revolutions, and parts of the ſcrew belonging to the mural arc into degrees, minutes, and ſeconds, with each other, at the ſame diſtance from the zenith on different ſides, and with their halves, quarters, &c. will find as notable a diſagreement of the ſcrew-work from the hand-diviſions, as had appeared before in the work of Mr. Tompion; and hence we may conclude, that the method of Dr. Hook, being executed by two ſuch maſterly hands as Tompion and Sharp, and found defective, is in reality not to be depended on in nice matters."

This inference of Smeaton obviouſly implies, that what he calls the *hand-diviſions* of the mural arc, are more accurate than the readings by the ſcrew alone; but, as he has given no other teſt of the accuracy of theſe hand-diviſions, nor has explained by what proceſs they were inſerted, the more legitimate inference would have been, that either the ſcrew, or the hand-diviſions may be faulty, or both may be ſo in their reſpective degrees. It is to be regretted that Sharp, who was a mathematician as well as a mechaniſt, has not publiſhed the method he adopted of marking out and cutting his dividing lines, which is more immediately the ſubject of our preſent article. Had he made his hand-diviſions firſt, and checked his notches, made by the ſcrew, thereby, as Ramſden did with his engine afterwards, his meaſures by the ſcrew would have been more perfect, though the centre-work might have been liable to be galled by too much preſſure of the ſcrew againſt the notched edge of the inſtrument, when frequently uſed.

Nearly about the time that the mural arc was fixed at Greenwich, Olaus Roemer, the Daniſh aſtronomer, ſupplied his domeſtic obſervatory with an inſtrument that had diviſions and teleſcopic ſights moving in the meridian, by means of a long axis, common to both the divided arc and teleſcope, which therefore admitted of better adjuſtment for the vertical motion than the mural arc was capable of; and which may be conſidered as the firſt *tranſit inſtrument* that properly deſerves ſuch a name. In dividing his arc, Mr. Roemer diſregarded the total length, with reſpect to an exact number of *degrees*, and looked more particularly to the equality of the diviſions, which were convertible into degrees and minutes, by a table calculated for this purpoſe. The method he made choice of, for rendering his diviſions equal, was to begin at one end of his arc, and to proceed by ſtepping, and by marking the dividing points with a proper preſſure at each ſtep, till the whole arc was finiſhed: for this purpoſe he did not depend on a pair of dividers, however ſtrong their legs, but two fine pointed pieces of ſtrong tempered ſteel were tied, or otherwiſe fixed together in ſuch a way, that the diſtance between the two points was $\frac{1}{12}$th or $\frac{1}{10}$th of an inch, and the radius of the arc to be divided was ſo proportioned, from $2\frac{1}{2}$ to 3 feet, that this diſtance made a ſpace very nearly equal to 10′; whether exactly ſo, or not, did not ſignify, as the difference was allowed for by the calculated table, when an angle had been read by the divided ſpaces as numbered. It is eaſy to conceive that this mode of meaſuring an angle would be as accurate as any other, after the due allowance was made, provided the ſpaces were perfectly equal to each other; but the theory of this method is more perfect than the practice; for none of the mixed metals is ſo perfectly uniform in its denſity, and ſo free from hard particles, occaſionally met with by the ſtepping points, as to enſure the perfect equality of the divided ſpaces, however carefully the ſtepping points are preſſed in a vertical direction; the ſmalleſt deviation on making the firſt impreſſion becomes greater by preſſure, and an attempt to rectify any erroneous points can never be depended upon: but, what is worſe, every individual deviation from perfect equality is charged on the whole arc, which therefore will be either longer or ſhorter than the true length, by the aggregate of all the poſitive, or negative quantities, that predominate in the inequalities of the individual ſpaces thus divided; and the longer the arc is from the firſt point, when any angle is meaſured, the greater is the error of the meaſurement in all probability, becauſe the greater is the probable aggregate of the deviations from perfect equality in the ſpaces. The total arc thus divided was about 75°; but as Roemer applied no correction to the errors of the diſtant diviſions of this arc, no dependence could be placed on the reſult of the readings, even when converted into degrees and minutes by his table, which ſuppoſed the arc perfectly divided.

The next ingenious artiſt who diſtinguiſhed himſelf in the art of graduating aſtronomical inſtruments, was the celebrated Graham. At the appointment of Dr. Halley to the Royal Obſervatory of Greenwich, Flamſtead's inſtruments were removed by his executors, and in the year 1725, Graham undertook the conſtruction of a new mural quadrant, which remains as a ſtanding proof of his ſkill, to this day, in the ſaid obſervatory. This artiſt availed himſelf of every contrivance that had been practiſed by his predeceſſors, and invented ſuch a ſtrong, and, at the ſame time, light method of conſtructing the frame-work of the iron quadrant, conſtructed by Jonathan Siſſon, as evinced his ſuperior knowledge of mechanics, as well as Siſſon's preciſion in the workmanſhip. The diagonals were now rejected, as being incapable of being read by a fiducial edge with requiſite exactneſs, and the vernier ſcale was ſubſtituted as much preferable in this reſpect, and the beam-compaſs, with equal advantage, was ſubſtituted for the ruler and dividing knife, which were liable to conſiderable parallax, notwithſtanding the greateſt precaution taken in drawing the dividing lines, or in marking the dividing points. The ſcrew for ſlow motion was alſo uſed for dividing the vernier ſcale in a proper way, after its value was aſcertained; and its perfection was enſured, with reſpect to the due inclination of its threads all round, as well as to the equality of their ſpaces: and laſtly, in order that the advantage of *continual biſection* might be introduced as a *check* on the degree ſpaces, the quadrant was divided in 96 ſpaces, with ſub-diviſions, in a ſeparate arc: and the readings from the 96th arc were a conſtant teſt of the readings by the 90°, when converted into degrees and minutes by calculation, or by a table uſed for that purpoſe.

As it is not our intention to deſcribe here the ſtructure of Graham's quadrant, but merely to deſcribe his method of graduating the limb of braſs, which was laid over the iron frame, we ſhall ſatisfy ourſelves by ſtating that two ſeparate arches were ſtruck by a beam-compaſs, ſecured from bending by ſeveral bracing pieces; the reſpective radii of which were 96 85, and 95.8 inches. The inner arch was divided into exact degrees, and twelfth parts of a degree, or 5′ ſpaces; but the outer one was divided, as we have ſaid, into 96 equal parts, and each of theſe again ſub-divided into 16 equal parts, ſo that the ſub-diviſions were to each other as 1080 : 1536, or in ſmaller number, as 25 : 32. To convey to the reader an idea how the arcs were divided, ſuppoſe the quadrant to be repreſented by *fig.* 1. of *Plate* XVIII. of *Aſtronomical Inſtruments*, and that the occult line *a b d* be required to be divided into degrees by points inſerted thereon, as centres for cutting the dividing lines from; the known property of the circle, that the chord of ſixty degrees is always equal to the radius, afforded the means of laying down the total arc of 90° in the firſt place; thus, from the point *a*, or zero of the arc, the point *b* was marked by meaſurement of the ſame points of the beam-compaſs unaltered, that ſtruck the occult line; and this arc of 60° was biſected at *c* by an extent nearly equal to the chord of 30 from the points *a* and *b* reſpectively; the extent, however, being a trifle leſs than the chord of 30°, the two ſweeps did not interſect each other, but approached ſo nearly together, that the ſmall ſpace between the ſweeping lines was biſected by a point put in by hand, by the aſſiſtance of a magnifying eye-glaſs: the diſtance of this point *c* from *a* or from *b* being the chord of 30°, was laid along the limb from *b* to *d*, the extreme point of the whole arc of 90°, and when this operation was ſo carefully performed, that the arcs *a c*, *c b*, and *b d* were preciſely of the ſame length, when compared with each other, the total arc might ſafely be depended on, as being of its true dimenſions. During this nice operation, it was preſumed, that the length of the dividing beam had not altered by any variation of temperature. The next ſtep was to biſect each of thoſe three arcs of 30° into ſix of 15° each, in the ſame manner as *a b*, the arc of 60°, was biſected into *a c* and *c b*: but the arcs of 15° were not diviſible into a lower number than three parts of each 5°; in order to tripartite each arc of 15°, a ſeparate arc was uſed, as an arc of trial, deſcribed by the original radius unaltered, and 15° were transferred to it, and divided by trial till one-third of it was aſcertained to meaſure exactly the diſtance between the two points of the compaſs; this diſtance was then laid off each way from each of the aforeſaid points of the arcs of 15°, and the ſecond ſpace of each being found equal to their contiguous firſt and third ſpaces thus meaſured, the whole arc was ſub-divided into 18 equal arcs of 5° each: in the ſame manner, a fifth part of one of the arcs of 5°, firſt transferred upon another part of the arc of trial, was aſcertained by repeated adjuſtments and examinations, and then inſerted within the diviſions of the divided arc, by turning the points over twice each way, from every point already laid down, and then the middle ſpace of each five being found equal to the extreme as well as contiguous ſpaces reſpectively, the whole arc was ſubdivided into points of one degree of diſtance from each other. But to enſure a perfect equality among theſe ſpaces required great ſteadineſs of hand, as well as obſervation of the eye, and caution, to preſerve the regulated diſtances of the points, unaltered during the operation. Of courſe, the marking point was required to be fine, and at the ſame time well tempered, as well as ſtrong enough to bear preſſure, which preſſure was alſo neceſſary to be made in a perpendicular direction on the face of the limb. The ſub-diviſions of the degree ſpaces into 12 parts of 5′ each, were done firſt by triſection, and then by biſection, or *vice verſâ*, in the manner we have already deſcribed; and the delicacy of theſe operations, on ſo ſmall a ſcale, required extraordinary attention and care to enſure perfect equality among the ſmalleſt ſub-diviſions, which were now in a ſtate to be transferred by lines tending to the centre of the arc to be graduated. This was an operation that could not be done well by the ſtraight edge of a rule, and a marking point, or dividing knife that would be liable to deviate a little, notwithſtanding the greateſt care; here another, but ſmaller beam-compaſs was ſubſtituted for the ruler, probably for the firſt time, for the purpoſe of transferring the graduated points from the occult arc into the arc to be graduated, in the following manner; ſuppoſe the points g and e to be intended to be transferred; becauſe the lines to be cut, as the dividing lines, are required to be in a direction tending directly towards the centre o of the concentric arcs, deſcribed on the limb; the diſtance of the cutting point, from the ſtationary point of the compaſs, was taken of ſuch a length, that the cutting point croſſed the arc to be cut at right angles, or, in other words, the beam was ſo ſituated, as to become a tangent to the arc to be cut; therefore the diſtance of the two points of the beam was regulated by the diſtance of the occult line of dots a, b, d, from the arc to be graduated by the ſtraight lines, or rather by the curved lines, which in fact were ſubſtituted, and which paſſed without ſenſible error for ſtraight lines, when the tangent line in queſtion was long. From the point or dot g, the curve $h\ k$ was drawn, and from the dot e the curve $f\ i$; but in ſuch a way that a ſmall portion only of each, that lies between the circular lines, was cut on the face of the inſtrument. In the ſame manner all the other dots were ſucceſſively transferred, while each repreſentative of the numerals 5, 10, 15, &c. were made longer than their intermediate lines of diviſion, and the ſub-dividing lines were again ſtill ſhorter. The vernier carried by the teleſcope, when nicely and accurately divided, would detect any inaccuracy in the ſub-diviſions thus transferred, by the aid of a magnifier properly adjuſted.

The arc of 96 diviſions, with their ſub-diviſions, was not, properly ſpeaking, *graduated*, but divided and ſub-divided into portions of ſmaller value than *degrees*, and 5′ ſpaces; but as the number choſen is diviſible continually by the number *two*, it was completed by *continual biſections*, which method therefore requires no further explanation. We are told by Dr. Smith (in his Optics) that theſe two arcs were never found to differ from each other more than 5″ or 6″ on any part of the limb, but that when there is ſuch difference, the preference ought to be given to the biſected arc of 96 diviſions.

To prove that the ſpaces obtained by the lines of transfer are equal to thoſe between the correſponding dots or points, let $e\ f$ and $g\ h$ be joined, alſo $o\ f$, $o\ h$, $o\ e$, and $o\ g$; and the triangles $e\ o\ f$, $g\ o\ h$, will be every way ſimilar, and equal to each other; therefore, if the common angle $e\ o\ h$ be taken away from the equal angles $e\ o\ f$, $g\ o\ h$, the angles $e\ o\ g$ and $f\ o\ h$, that remain, will alſo be equal to each other.

It does not appear that Graham took any meaſures to guard againſt, or even to detect the errors that his method of dividing is liable to, from variations of temperature in his quadrant and beam, during the time that the operation is going on, and from the correſponding variations of length in the metals, according to their reſpective expanſibilities; nor is it quite certain that he was aware of the probable extent of ſuch errors, ſeeing he conſtructed the frame-work of his inſtruments of iron, and had his circle to be divided of braſs. In Dr. Bradley's zenith ſector made by Graham, Dr. Maſkelyne has cauſed an iron limb to be ſubſtituted for the original braſs one, and has had the points of diviſion inſerted on ſtuds of gold, to avoid the errors that aroſe from the unequal expanſibility of the different metals.

We might here mention Mr. H. Hindley's plan of dividing a circle by a toothed circular plate and endleſs ſcrew in form of an engine, about the year 1740, but that we think his method of dividing and drilling the holes of his plate, by bending a ſtraight ſlender bar of braſs into a circle, and transferring the holes therefrom, cannot be depended on where much accuracy is required in the diviſions of a circle. It was originally intended, and is much better calculated, for dividing and cutting the notches between the teeth of a wheel; but the reader may ſee the plan deſcribed, and ſome improvements on it propoſed by Smeaton, in his paper already mentioned, as contained in the Philoſophical Tranſactions of London, in the year 1785.

Jeremiah, the ſon of Jonathan Siſſon, was of Graham's ſchool of dividing, and did nearly as much juſtice to the method he adopted, as Graham himſelf, probably; and his nice care, and perſevering aſſiduity, have claſſed him among the firſt dividers of his time; but we are not aware that he was the inventor of any original contrivance, except, perhaps, that he applied a triple index to ſome of his inſtruments, one of which had the vernier, and each of the others had a ſingle line or ſtroke drawn at one-third of a circle from each other, and from zero of the vernier, which might act as a check on the eccentricity of the circle, as well as on the inequality of its diviſions; though it does not appear certain that this was the original intention, as the three props of his vernier-bar in his theodolites required it to be triple; but in his circular indexes one ſtroke only was made, and that oppoſite the vernier: the importance of a triple vernier has not been noticed particularly by any one, previouſly to the time of Mr. Ed. Troughton's introduction of the triple vernier into his circular inſtruments. Mr. Ludlam, however, ſays, that Siſſon very early rejected the method of triſecting, and that of ſtepping too. "Having (by means of the radius and biſections only) divided his quadrant into three arches of 30° each, he ſet off in each of theſe arches the chord of 21° 20′, or 256 times five minutes. This chord was taken off a ſcale of equal parts, and was checked by the chord of 8° 40′, both chords together filling up the arch of 30°. The arch of 21° 20′ was divided by continual biſections into arches of five minutes each." This deſcription, ſays Mr. Ludlam, in a note to page 4, of his Introduction and Notes on Mr. Bird's method of dividing, was given by Jeremiah Siſſon, in a private letter dated May 20, 1766; and according to the ſame letter it appears alſo, that Siſſon placed the fixed or central point of his compaſs in a blank tangental line, as hereafter deſcribed by Bird, during the operation of transferring the divided points into linear diviſions; but as Bird has in the year 1767 publiſhed theſe proceſſes as originally his own, and as he worked for the Siſſons previouſly to 1766, we are diſpoſed to conſider Bird, and not either of the Siſſons, as the real contriver of the methods here adverted to. Siſſon (the younger) rejected the arc of 96, as being only a help to a bad divider; but Bird uſed to retort on him, by ſaying, that good dividing was not afraid of ſuch a teſt of its accuracy.

It is the characteriſtic of a great genius in mechanics, not to tread too cloſely in the ſteps of his predeceſſors, but, availing himſelf of any hints that may have been preſented to him, to mark out a more direct and even path for himſelf, that ſhall throw in his way fewer obſtacles to impede his progreſs. This was the caſe with Mr. Bird, who, having been brought up a cloth-weaver in the county of Durham, and having noticed ſome very coarſe diviſions on the face of a clock that fell in his way, immediately ſet about dividing one himſelf, in a much neater manner, and was ſo pleaſed with his ſucceſs, that in the year 1740 he came to London, and was in buſineſs for himſelf as an inſtrument-maker, only five years afterwards. After having made himſelf acquainted with the methods at that time in uſe of dividing a circle, he ſaw that no one had guarded againſt the errors produced by the effects of variable temperature on the beam of the compaſs, as well as on the metal of the ſcales and circles to be divided; he alſo ſaw that biſection of an arc had ſo much advantage over triſection, or quinqueſection, that he abandoned the latter modes of dividing altogether, and was the firſt probably to compute chord-lines, to be taken from a good *vernier* (what he calls *nonius*) ſcale, by the beam-compaſs, in order to determine ſuch points in an arc of 90°, as may enable a diviſion by continual biſection to be adopted, and at the ſame time ſuch as may be laid down without loſs of time, or, in other words, without ſenſible change of atmoſpheric temperature.

We cannot better deſcribe Mr. Bird's method of dividing aſtronomical inſtruments than by uſing his own words. "The requiſites," ſays he, "for the performance of this work are as follow: A ſcale of equal parts, by which the radius may be meaſured to 0.001 of an inch muſt be provided. My ſcale is 90 inches long, each inch divided into 10, contiguous to which are nonius (vernier) diviſions, *viz.* 10.1 inches divided into 100 equal parts, ſhewing 0.001 of an inch, and by the aſſiſtance of a magnifying glaſs, of one inch focal length, a third of 0.001 may be taken off by eſtimation.

"Provide fine beam-compaſſes, to which magnifying glaſſes of not more than one inch focal length ſhould be applied. Let the longeſt beam be ſufficient to draw the arcs, and meaſure the radius; the 2d to meaſure the chord of 42° 40′; the 3d to meaſure the chord of 30°; the 4th, 10° 20′; the 5th, 4° 40′; and if a ſixth, to meaſure 15°, be made uſe of, ſo much the better.

"The radius of the arc of 90° at the points is equal to 95.938 inches, from which the following numbers were computed, *viz.* 49.6615 inches = chord of 30°; 25.0448 inches = chord of 15°; 17.279047 inches = chord of 10° 20′; 7.81186 inches = chord of 4° 40′; and 69.80318 inches = chord of 42° 40′. Having drawn the ſeveral arcs, between which the diviſions were to be cut, the radius and the lengths of the above chords were taken by the beam-compaſſes, which, together with the ſcale, were laid upon the quadrant, where they remained till the next morning; during which time the door of the room was kept locked. Before ſun-riſe I re-meaſured the radius, which required ſome correction; the beam being of white fir, and the ſcale of braſs, which probably contracted, while the beam remained unaltered: the other beam-compaſſes alſo required correction. Now the quadrant and ſcale being of the ſame temperature, the faint arc *b d* (*fig.* 2. of *Plate* XVIII. of *Aſtronomical Inſtruments*,) was ſtruck, and with a very fine prick-punch (pointril) the point *a* was made; with the ſame beam-compaſs unaltered I laid off from *a* to *e* the chord of 60°, making alſo a fine point: with the chord of 30° *a e* was biſected in *c*. Now one point of the beam-compaſſes containing 60° was fixed in *c*, and with the other was marked the point *r* or 90°: next, with the beam-compaſſes containing 15°, was biſected *e r* in *n* or 75°; from *n* was laid off the chord of 10° 20′; and from *r*, 4° 40′; which two laſt chords joined exactly in *g*, being the point of 85° 20′: now each degree being to be divided into 12 parts, or every 5′, therefore, $\overline{85 \times 12} + 4 = 1024$, a number diviſible by continual biſections. The laſt chord computed was 42° 40′, with which *a g* was biſected in *o*; *a o* and *o g* were biſected by trials: but, whoever undertakes to divide a large quadrant, will do well to compute alſo the chord of 21° 20′; but for this chord any of the beam-compaſſes already provided, which will take in the length, may be uſed. The point *g*, being formed as above, I proceeded, by continual biſections, till I had the number required, *viz.* 1024. To fill up the ſpace between *g* and *r*, containing 56 diviſions, the chord of 64 diviſions was laid off from *g* towards *d*, and divided like the reſt by continual biſections; as was alſo from *a* towards *b*. The points 30°, 60°, 75°, and 90°, fell in without any ſenſible inequality."

So much will ſuffice for giving a general idea of Bird's proceedings, in *dividing* his aſtronomical inſtruments; but his method of transferring the divided points into dividing lines was equally original, and guarded alſo againſt errors that might ariſe from the handling of the beam during the operation, by variable temperature; before, however, we proceed to detail this proceſs, it may be proper to obſerve, that the points made on the faint circle were inſerted by a pointril, or piece of ſteel-wire, with a conical point made faſt into a piece of cylindrical braſs rounded at the upper end: the ſteel part was $\frac{1}{10}$th of an inch thick, and $\frac{3}{4}$ths of an inch long, and the braſs part $2\frac{1}{2}$ long, and $\frac{1}{6}$th of an inch in diameter. The angle of the ſteel conical point was from 20° to 25°, and the point ſomewhat above a ſpring temper, ſo that the point made in the circle did not exceed 0.001 of an inch; as it was ſharpened on an oil-ſtone while turning round, and while drawn in a direction outwards from the point itſelf, the ſurface partook of the nature of a counter-ſink, and, as it were, drilled a diminutive hole of a conical ſhape when gently preſſed on, as it revolved in the point of biſection, which point, by reaſon of the four angular burs made by the interſecting lines, could be *felt* as well as *ſeen*. The points of the beam-compaſſes were never made to approach nearer to each other than two or three inches, but at the ends of the arcs ſpring dividers, with conical points, were ſubſtituted to meaſure ſmall arcs. Another precaution was, that in all biſections, the place to be pointed was laid off from left to right, and then from right to left, from the reſpective central points.

As the maxim, "that an arc may be *biſected*, but not practically *triſected* or *quinqueſected* with certainty," was the maxim adopted by Bird, when he introduced the uſe of his ſcale for meaſuring the chords, ſo the maxim, "that a right line cannot be cut on braſs, ſo as accurately to paſs through two given points, but that a circle may be deſcribed from any centre, to paſs accurately through a given point," was taken up by him when he adopted the beam-compaſs, as Graham and Siſſon had done, for cutting the ſmall portions of a circle, inſtead of perfectly ſtraight lines, as boundaries of the diviſions. His plan of doing this, however, was new, as may be ſeen from his own words.

"The next ſtep," ſays he, "is to cut the linear diviſions from the points: the beſt inſtrument for this purpoſe is the beam-compaſs, having both its points conical and very ſharp. Draw a tangent to the arc $b\,d$, ſuppoſe at e, it will interſect the arc $x\,y$ in q, this will be the diſtance between the points of the beam-compaſs to cut the diviſions (nearly) at right angles to the arc $b\,d$. Lodge that point of the beam-compaſs next your right hand, in the point r; let the other fall freely into the arc $x\,y$; preſs gently with your finger upon the ſcrew-head that faſtens the ſocket (and that is convex), and with the point towards the right hand cut the diviſions. In this manner you muſt proceed with the reſt."

The intention of transferring the central or reſting point of the compaſs into a blank tangental line, inſtead of ſuffering the ſaid point to reſt in the reſpective points made in the faint arc, is, that in the former caſe ſhould any alteration take place in the length of the beam, during the operation of cutting, no error is charged on the diviſions cut, but the alteration is compenſated by the diſtance of the newly made point in the tangental line from the cutting point; that is, each diviſion is charged only with ſuch a minute error, if any, as ariſes from temperature during the act of cutting a ſingle ſtroke, and if one of the points ſhould break, another may be replaced without inconvenience; whereas, by the method of Graham, a broken point produces conſiderable difficulty; and the whole error ariſing from temperature, during the whole proceſs of cutting all the diviſions, is charged not only on the total arc, but likewiſe in a certain undefined degree on each of the whole diviſions. This idea of getting quit of the effects of temperature is ingenious, but has been objected to as liable to the ill effects of ſtepping in a certain degree, inaſmuch as that a hard particle, lying under the point of reſt, may cauſe a little deviation in the diſtance, before the ſtroke is cut. This objection, however, was not allowed to be realized by Bird, who no doubt muſt have obviated it by ſome other plan, had he found any real inconvenience ariſing from it. Great care, notwithſtanding, muſt have been taken in ſetting down, and preſſing on the point at reſt, in a perpendicular direction. Another objection applied to Mr. Bird's ſcale, from which the chord-lines were meaſured, inaſmuch as the ſcale itſelf might be erroneous in ſome places, and would impart its errors to the arcs meaſured from the computed chords taken therefrom.

Beſides the arc of 90°, the mural arc by Bird had an arc of 96 diviſions, like Graham's, divided by continual biſections, till each of the 96 diviſions had 16 ſub-diviſions, as a check on the accuracy of the arc of degrees; but ſubſequent dividers of aſtronomical inſtruments have found this ſuperfluous, as being in the opinion of others, as well as of Jeremiah Siſſon, a check only on bad dividing, and as rendering the reduction of obſervations troubleſome, when made thereby.

The vernier was retained by Bird as the beſt method he knew of ſub-dividing the 5′ ſpaces into quantities of 30″ each, which was the ſmalleſt angle he profeſſed to meaſure; and to effect his purpoſe he made ten diviſions on his vernier equal to eleven on the limb of the inſtrument, firſt by computing the chord of thirty-two parts, and then by taking ten out of thoſe parts, when biſected, as the proper diviſions for the vernier; theſe, being made in points, were alſo transferred by a tangental line into linear diviſions by the beam-compaſs, as before deſcribed; but great care was taken, that the ſtroke zero on the vernier was drawn from the quadrant's centre, preciſely parallel to the line of collimation of the teleſcope. Mr. Ludlam ſays, that the cutting-point which Siſſon uſed was flat in the knife-edge form, but that Bird's was a triangular priſm, with a ſlope ground down to a point at one of the angles; which formed the cutting-point.

At the requeſt of the commiſſioners of the Board of Longitude, Mr. Bird, in the year 1767, publiſhed his method of dividing in a quarto pamphlet, for which they rewarded him with 500*l.* beſides 60*l.* for his plates, after having bound him to inſtruct an apprentice of ſeven years in the art of conſtructing and dividing aſtronomical inſtruments.

Mr. Smeaton is of opinion that Bird's method of dividing may be improved in one reſpect, and expreſſes himſelf on the ſubject thus:

"I muſt here obſerve that I apprehend no quadrant, that has ever undergone a ſevere examination, has been found to form a perfect arch of 90°, nor is it at all neceſſary it ſhould; the perfect equality of the diviſions throughout the whole is the firſt and primary conſideration; as the proportion of error, when aſcertained by proper obſervations, can be as eaſily and readily applied when the whole error of the rectangle is fifteen ſeconds, as when it is but five. In this view, from the radius taken, I would compute the chord of 16° only. If I had an excellent plain ſcale, I would uſe it, becauſe I ſhould expect the deviation from the right angle to be leſs than if taken from a ſcale of more moderate accuracy; but if not, the equality of the diviſions would not be affected, though taken from any common diagonal ſcale. This chord, ſo prepared, I would lay off five times in ſucceſſion, from the primary point of 0 given, which would compleat 80°; I would then biſect each of thoſe arches of 16°, as preſcribed by Mr. Bird, and laying off one of them beyond the 80th, would give the 88th degree, proceeding then by biſection, till I came to an arch of 2°, laying that off from the 88th degree, would give the point of 90°. Proceeding ſtill by biſection, till I had reduced the degrees into quarters of 15′ each, I would there ſtop, as from experience I know that when diviſions are over cloſe, the accuracy of them, even by biſections, cannot be ſo well attained, as where they are moderately large. If a ſpace of $\frac{4}{10}$ths of an inch, which is a quarter of a degree, upon an eight feet radius, is thought too large an interval to draw the index over by the micrometer ſcrew, this may be ſhortened by placing another line, at the diſtance of one-third of a diviſion on each ſide of the index line, in which caſe the ſcrew will never have to move the index plate more than one-third of a diviſion, or 5′, and the perfect equality of thoſe ſide lines from the index line may be obtained, and adjuſted to 5′ preciſely, by putting each of the ſide lines upon a little plate, capable of adjuſtment to its true diſtance from the middle one, by an adjuſting ſcrew. The above hint is not confined to the chord of 16°, which prohibits the ſub-diviſion going lower than 15′; for if it be required to have diviſions equivalent to 5′ upon the limb itſelf, then I would compute the chord of 21° 20′ only; and laying it off four times from the primary point, the laſt would mark out the diviſion 85° 20′, pointed out by Mr. Bird, ſupplying the remainder to a quadrant from the biſected diviſions as they ariſe, and not by the application of other computed chords." Mr. Smeaton, ſenſible, however, that this method of laying 16° five times over, or 21° 20′ four times over, may be objected to, as liable to the errors of *ſtepping*, ariſing from Roemer's method, afterwards propoſes to lay down the chord of 64°, or of 85° 20′, from computation all at once, and then to biſect, and complete the quadrant from the biſected diviſions, which Mr. Bird himſelf preſcribed as a good method for Hadley's ſextants and octants. But theſe plans are now ſuperſeded for inſtruments of ſmall radius by the dividing engine, which performs the work with great expedition, as well as accuracy, and the original methods of dividing the circle are only uſeful for the larger inſtruments, and for the finiſhing of the dividing engines themſelves.

In the year after Mr. Bird had publiſhed an account of his method of dividing aſtronomical inſtruments, the duc de Chaulnes printed in French a folio work, entitled "Nouvelle methode pour diviſer les Inſtrumens de Mathematique et d'Aſtronomie," and alſo a work proper to be bound with the former, called "Deſcription d'un Microſcope et de differens Micrometres deſtinés a meſurer des parties circulaires ou droites avec la plus grande preciſion." The former of theſe pamphlets contains 15 plates, and the latter ſix, which exhibit plans and drawings in different points of view, of all the apparatus, both in pieces and together; theſe are not neceſſary to be copied by us, but we will deſcribe them as far as they fall within our preſent purpoſe. This new method of dividing is performed by the aſſiſtance of compound microſcopes, with croſs hairs in the focus of the eye-glaſs of each, to be fixed to the circle to be divided in any given ſituation, and of moveable pieces of braſs with fine dividing lines marked thereon, which may be ſo fixed with wax, as to be adjuſtable to the point of interſection in the focus of any of the microſcopes, and when duly adjuſted, a ſliding pointril, moving in a complex frame of braſs, cuts the line, on the circle to be divided, that ſhall correſpond to the point of the circle where the adjuſtable diviſion is fixed; though the line cut is not in the ſame part of the circle. As this method may be conſidered as the ground-work of Ramſden's method of dividing a large circle, and has not, that we know of, been tranſlated into our language, we will give the ſubſtance of that part of the work which more immediately relates to our preſent ſubject, without following the author through all his minute details. The circle, which the duc de Chaulnes propoſes to divide by his original method, is the table of his dividing engine, but as it is equally applicable to any circle that may be fixed concentrically on it, we will ſuppoſe it an aſtronomical circle for altitudes or azimuths that is to be divided by his method. In the firſt place, he propoſes to have from 30 to 40 thin pieces of ſmooth braſs about one-third of an inch long, and one-ſixth broad, having each a fine ſtroke drawn acroſs, perpendicular to the long ſides and juſt deep enough to be ſeen; and ſecondly, three compound microſcopes are to be provided, one to be *fixed* diametrically oppoſite the pointril, or cutting point, that is carried in and out, *i. e.* towards and from the centre of the circle by an adjuſtable frame, and the other two are adjuſtable to any given points along the plane of the circle to be divided. When the circular lines are ſtruck on, the adjuſtable microſcopes, which we will call A and B, are placed as oppoſite to each other, in a diametrical line, as can be gueſſed, or roughly meaſured by any of the ordinary means, and a moveable diviſion on a piece of braſs already deſcribed, is put by means of wax under each of the two microſcopes, and moved by hand, till the lines, which muſt be in a radial direction, fall reſpectively under the centres or interſecting points of the fields of view; theſe microſcopes, it muſt be underſtood, are fixed, not on the table which bears the circle, and which is made ſo as to revolve on a long vertical axis, but on a fixed or ſtationary ſurrounding frame, that is unconnected with the table itſelf, when the table is at liberty to revolve; ſuppoſe now the table and circle on it to be carried half round, while the microſcopes remain fixed, in ſuch a way that the moveable diviſion which was under the microſcope A, falls under the centre of microſcope B; in this ſituation, if the oppoſite diviſion falls under the centre of A, the circle is truly biſected; but as this is not likely to be the caſe at the firſt trial, the quantity that is over or ſhort muſt be adjuſted, one half by the moveable diviſion, and the other by the microſcope, and the operation of reverſing muſt be repeated, and the rectifications made, till the circle is found to be truly biſected, both backwards and forwards, by the coincidence of the diviſions with the interſected points in each focus of the microſcopes. The two microſcopes A and B may now be removed, and the third or fixed microſcope muſt be made faſt over one of theſe two dividing ſtrokes, after the pointril has been brought preciſely to occupy the place of the other, in which ſituation the pointril and the fixed microſcope will ſtand ſo diametrically oppoſite each other, that whenever an adjuſtable line is brought to biſect the field of view of this microſcope, the pointril will be ready to cut a line on the oppoſite ſide of the circle, and whenever a ſet of adjuſtable diviſions are properly placed, by the wax, on one ſemi-circle, the lines in the other ſemi-circle, directly oppoſite theſe reſpectively, can be permanently cut, before the moveable pieces are taken off, and afterwards the ſaid lines ſo cut may be brought ſucceſſively under the fixed microſcope, in order that their oppoſites, where the moveable pieces were ſtuck on, may, in like manner, be cut; ſo that one-half of the circle will be ſufficient to be divided and ſub-divided by the adjuſtable pieces, ſeeing that each of its diviſions and ſub-diviſions, brought in ſucceſſion under the fixed microſcope, may be inſtantly transferred by the pointril, into the oppoſite ſemicircle, and alſo theſe in their turn transferred back again. Let us now ſee how the ſemi-circle is divided and ſub-divided by means of the two microſcopes A and the fixed one, B being no longer wanted; the firſt operation is the triſection of it into arcs of each 60°; for this purpoſe, while the pointril remains at T, (*fig.* 3. of *Plate* XVIII.) one of the points cut, *viz.* at 180°, and the fixed microſcope reſts at Z, or zero, *i. e.* the firſt point of the circle, to be figured 0 or 360°; two moveable pieces are ſtuck on at C and D reſpectively, ſo as to triſect the ſemi-circle Z B T very nearly, and the microſcope A is placed directly over C, ſo as to view its ſtroke or line at the point of interſection in the focus of the eye-glaſs; there it is made faſt for the preſent; the line C is now brought under the fixed microſcope at zero, by making the circle revolve, and ſuffered to remain; the piece D has its ſtroke put under the microſcope A, as before was the caſe with piece C, now at zero; the circle is again made to revolve till the ſtroke of D is under the fixed microſcope at zero; in this ſituation the point T, or 180°, will have been brought forward 120°, or 60° twice over, provided the pieces C and D were truly placed, and in this caſe an eye, looking into the microſcope A, will ſee this dividing line biſect the field of view; but as this is not likely to happen at the firſt trial, the microſcope muſt be moved one third of the error now ſhewn, and each of the pieces C and D another third, accordingly as the portions of the ſemi-circles Z C, C D, and D T taken together, are found to be more or leſs than an exact ſemi-circle. The operation we have here deſcribed is repeated again and again, till the three equidiſtant arcs amount to an exact ſemi-circle; after which they are rendered permanent, by ſtrokes made ſucceſſively on the oppoſite ſemi-circle, at the points *c* and *d*, which triſect the ſemi-circle T A Z, when the adjuſtable ſtrokes C and D are in ſucceſſion exactly fixed in the centre of the field of view of the fixed microſcope. The diſtance between the two microſcopes, which is here 60°, is called the *opening* of the microſcopes, which are conſidered as the two points of a pair of dividers, and the arc between them is therefore denominated accordingly.

The next ſtep is to biſect the arcs of 60° each, into two of 30°, by an opening of 30°; to do this one moveable piece, ſtuck at the middle of each arc of 60°, will be requiſite, and the two halves, to the right and left of each piece, may be examined and adjuſted till the biſections are complete, and in a ſtate to be transferred into the oppoſite ſemi-circle; for inſtance, ſuppoſe the arc of 60° from Z to C to be biſected, put a moveable ſtroke at 30°, more or leſs, and place the microſcope A over it; make the table and circle revolve till this ſtroke 30° falls under the fixed microſcope; in that ſituation, the ſtroke 60° ought to biſect the field of view of microſcope A, and whatever the deviation may be, plus or minus, it muſt be adjuſted by trial, partly by moving the microſcope A, and partly by moving the piece with the ſtroke on at 30°, when brought back again under the microſcope A. In the ſame way, any other biſection may be made within the poſſible opening of the microſcopes. Again, the arcs of 30° are triſected, as before deſcribed, into arcs of 10°, which are all transferred into the oppoſite ſemi-circle in ſucceſſion.

With reſpect to the diviſion of the arcs into ſmaller quantities than thoſe of 10°, where the microſcopes approach too near together to admit of the neceſſary adjuſtments, an ingenious mode of ſub-dividing is adopted by a property of the number 9, thus; having all the arcs of 10° round the ſemi-circle laid down, the points 90° and 180° are of courſe among them, and as theſe are diviſible by 9, an opening of nine degree's is taken by trial, which repeated ten times, by means of the moveable ſtrokes, will reach from 0 to 90°, when properly adjuſted; beſides the 10°, 20°, 30°, &c. there will now be 9°, 18°, 27°, &c. up to 90°, and alſo 99°, 108°, 117°, &c. up to 180°, and the differences or ſpaces left between the diviſions obtained from 10°, and thoſe from 9° repeated, will be reſpectively 1°, 2°, 3°, &c. up to 9°; now, if the points 9°, 18°, 27°, &c. which numbers decreaſe by unity in the units place, be made in ſucceſſion points of commencement, for the arc of 10° to be repeated from, they will from 9° produce 19°, 29°, 39°, &c.; from 18° they will give 28°, 38°, 48°, &c.; and from 27° they will give 37°, 47°, 57°, &c. and ſo of the reſt, till all the ſingle degrees are put on by the arc of 10° thus applied from the points derived from 9° and its multiples. The work is performed thus: make the opening of the microſcopes again 10°, by fixing the one called A at the tenth degree when zero is at the fixed one, then turn the table and ſuperincumbent circle to be divided till the ſtroke 9° comes to zero, then a moveable piece ſtuck properly under A will be 19°; bring this to the fixed microſcope, and the place for 29° will be had for the next ſtroke, under A again; and in like manner every individual degree may be marked in ſucceſſion, by taking thoſe ending with 8, after thoſe ending with 9 have been gone through; and after that, thoſe ending with 7, with 6, with 5, &c. till all the numerals are included. If the circle is large enough to admit of diviſion to 5° by the opening of the microſcopes, the numbers 4 and 5 may be ſubſtituted with advantage for 9 and 10, and then the opening may be 20° for inſerting them, inſtead of 10°, as in the mode we have deſcribed. When half degrees are required to be inſerted 15° may be biſected, and the line obtained will be in the middle between 7° and 8°, from which ſtroke, with an opening of 15°, all the other half degrees may be marked as before, by the aid of the adjuſtable marks to be transferred afterwards into the oppoſite ſemi-circle, and all the ſtrokes in that ſemicircle may then be transferred back again permanently, ſo as to compleat the circle.

The uſe of the numerals nine and ten, or of the four and five, is evidently borrowed from Clavius the Jeſuit, whoſe problem for thus dividing a right line, or arc of a circle, was publiſhed in 1611.

Another method of ſub-dividing the circle, when marked into degrees, as above deſcribed, is alſo propoſed as being leſs tedious, and capable of carrying the ſub-diviſions to a lower denomination; thus, a ſocket is made to fit the arbor of the revolving table that carries the circle to be divided, ſo tight, that it will revolve with the ſaid arbor, or without it, as the caſe may be: to this ſocket a teleſcope is fixed with a vertical hair in the focus of its eye-glaſs, that may biſect any diſtant mark to which it may be directed, then a long ruler, of ſix or ſeven feet in length, is divided, for inſtance, into twelve equal parts, ſo that it may be read diſtinctly; the diſtance of this ruler is ſo adjuſted from the teleſcope, that when placed at right angles to the line of collimation, it may juſt ſubtend *one degree*, which may be firſt calculated nearly, and then adjuſted by trial, till the run of the teleſcope over the twelve marks of the ruler be exactly correſponding to the run of one degree of the circle under one of the microſcopes. In this ſituation of things, the diviſions of the ruler, as ſeen through the teleſcope, are, with great care and ſteadineſs, transferred in ſucceſſion, not to one of the degree ſpaces itſelf on the circle, but to a pattern-piece of braſs, which may be afterwards fixed with ſcrews under the object lens of the fixed microſcope, ſo as to be applied in ſucceſſion to each ſeparate degree, as the circle is made to revolve, during the operation of transferring theſe five minute ſpaces, to the oppoſite parts of the circle, by means of the pointril. In ſtrictneſs, the ruler, viewed through the teleſcope, ought to be a portion of a circle; but the arc and the chord of one degree are ſo nearly alike, that one may be ſubſtituted for the other, without ſenſible error. When ſmall circles, or parts of a circle, were propoſed by the duc de Chaulnes to be divided, they were fixed on the revolving arbor of the table, and the microſcopes and cutting point were ſo arranged, that the diviſions of a large divided circle were transferred to the ſmall one in ſucceſſion, and the whole apparatus, ſo arranged, conſtituted an *engine* for dividing; but the work could not be performed with ſuch expedition as with our modern engines, where ſtops are ſubſtituted for the microſcopes, and where the *touch* has greatly the advantage over the *ſight*. With reſpect to the accuracy of the work performed by the duc de Chaulnes, we are greatly inclined to believe, that the ſliding mechaniſm of the cutting-point would not ſecure the ſtrokes from having a devious direction ſometimes, ariſing from the neceſſary liberty that the ſliding parts muſt have had to admit of free motion, unleſs, indeed, the parts of action were fitted with extreme nicety.

Laſtly, the vernier ſcale was retained by the author before us, as the beſt ſub-divider of the 5′ ſpaces, or other ſmall diviſions; but he has not conceived it neceſſary to deſcribe, in detail, how he proportioned it to the diviſions of his circle, though it is eaſy to conceive how this may be done by the help of microſcopes and the cutting-point. Our remark on this original method of dividing is, that it ſhews great ingenuity; but we conceive, that making an equality in the divided and ſub-divided *arcs* will not always enſure perfection in the *angular meaſures*, becauſe the axis of motion may be out of the centre of the divided circle, and the eccentricity will neither be detected by this method, nor allowed for in the diviſions and ſub-diviſions, unleſs, indeed, two or three equidiſtant verniers were uſed for taking an average of the readings from different ſides of the circle. It is ſomewhat remarkable that the ſame thought that introduced the microſcopes for meaſuring the arcs to be divided, did not ſubſtitute them for the vernier, in reading off ſmall quantities of a ſub-diviſion when an inſtrument was finiſhed; which practice was left for Mr. Ramſden afterwards to adopt. The ſecond ſemi-circle, being only the copy of a copy, renders this method of dividing leſs worthy of imitation, as an original method, than it would have been if the imperfections of the firſt portion of the circle had not been neceſſarily transferred to the other, and from that back again. In ſhort, we think the wax-work might have been better employed.

The elder Troughton (John) whoſe dividing was acknowledged to be equal to that of any of his predeceſſors, or contemporaries, uſed the beam-compaſſes, like Bird, but rejected the computation of chords, and the meaſures taken from ſcales, as being liable to uncertainty in determining the primary points from which the biſections were to proceed. After having deſcribed his circle, or rather quadrantal arc to be divided, he determined the point 60° with the radius, as Graham and Bird had previouſly done, and, having biſected it at 30°, ſet off 30° in addition to the 60° to complete the arc of 90°; he then biſected till he had arcs of 15°, and again till he had 7° 30′ in each diviſion: the two marks neareſt to 90° were now 82° 30′, and 86° 15′; but the point 85° 20′, or limit of the largeſt biſectional arc, lay between theſe two, and could not be obtained by further biſections; the ſpace between the two marks in queſtion was therefore triſected, and the more forward of the two new points was 85°: again, the ſpace between this mark of 85°, and that of 86° 15′, was triſected; from which came 85° 25′, as denoted by the more backward of the two new marks; and laſtly, a fifth part of one of the ſub-divided arcs was ſet backwards from 85° 25′, to 85° 20′, the point from which the 1024 diviſions were inſerted from 0 entirely by biſections. The quadrantal arc was then completed from the ſub-diviſions thus obtained. It may be neceſſary, however, to obſerve, that the marks at firſt made by the radius, biſections, triſections, &c. were none of them permitted to be permanent, being of no further uſe than to aſcertain the individual point 85° 20′, from which the ſubſequent biſections were to commence. This method is conſidered as being preferable to Bird's method of computing the chords and uſing the ſcale, inaſmuch as it does not depend on ſecondary or auxiliary means of aſcertaining the primary point in the biſectional arc. It has uniformity of means to recommend it in preference to thoſe mixed methods that depend partly on computation, and partly on the extended radius.

The method of dividing a large circle, commonly known by the appellation of *Ramſden's method*, or the method of *coaxing*, conſiſts of Bird's method, and of that propoſed by the duc de Chaulnes united: the circle is firſt divided by the beam-compaſſes into primary points; and the true ſituation of each of theſe points is aſcertained by oppoſite microſcopes, as the work proceeds, and is rectified accordingly, by puſhing the points forward or backward a trifle, till they are in their true places. This method, now generally practiſed by all the beſt dividers, except the preſent Mr. Troughton, has not, that we know of, been very particularly deſcribed, with references to drawings, &c. though it is capable of conſiderable accuracy in the hands of a good workman, who has perſeverance enough to do juſtice to it. The great number of points that will require to be rectified, will, notwithſtanding the utmoſt precaution, render the work irregular in its appearance, and a circular line muſt neceſſarily paſs through the centre of all the points or conical holes, to render them concentric; beſides, the biſectional arcs deform the conical ſhape of the points, by paſſing through them, and the ſubſequent eraſures muſt leave an unevenneſs in the metal that cannot but offend a nice eye. Sir George Shuckburgh, in his paper on the equatorial, calls the points that have been enlarged by rectification, and burniſhed level again, "doubtful or bad points;" and theſe bear a conſiderable proportion to the whole. "It would," ſays Mr. Troughton, "be a great improvement of this method to divide the whole by hand at once, and afterwards to correct the whole; for a dot, forced to its place, as above, will ſeldom allow the compaſs-point to reſt in the centre of its apparent area; therefore, other dots made from thoſe will ſcarcely ever be found in their true places. This improvement alſo prevents the corrected dots from being injured or moved by the future application of the compaſſes, no ſuch application being neceſſary."

The circle that is divided by this method is placed horizontally to have its firſt points made, after it has had its circle deſcribed from a revolution on its own axis, and then it is placed vertically in a frame, in which it revolves, and which carries the microſcopes with micrometers, that ſub-divide, and read to the accuracy of one ſecond, in order that the ſemi-circles, taken from any given oppoſite points, may have their equality aſcertained, or their deviation therefrom determined previouſly to final rectification. In theſe operations great attention is paid to the temperature of all the metallic parts employed in the work.

Mr. Ed. Troughton has deviated from the beaten track of his predeceſſors, and made a road for himſelf, (probably before Ramſden's plan was adopted,) that he has trodden with great ſucceſs, and which he has fully deſcribed in a paper of the Philoſophical Tranſactions of the year 1809, which gained him Copley's medal. The reaſon that cauſed him to think for himſelf on this ſubject, as he has done ſucceſsfully on many others, ſeems to have been this: "With as ſteady a hand, and as good an eye," ſays he, "as young men generally have, I was much diſappointed at finding, that after having made two points, neat and ſmall to my liking, I could not biſect the diſtance between them without enlarging, diſplacing, or deforming them with the points of the compaſſes."

This diſcovery led to the abandonment of the beam-compaſſes and ſpring-dividers, and, the art of turning appearing to have approached the neareſt to perfection of any of the mechanical arts, a *roller* was thought of, which by its revolutions might ſub-divide the circumference of a circle rolled over, after the ratio of their reſpective diameters was aſcertained and properly adjuſted. When this ſpeculation was firſt attempted to be realized, ſome circumſtances occurred which could not be certainly inferred from reaſoning, *à priori*, from known data, but of which a perfect knowledge was neceſſary for the conſummation of the project; in the firſt place, it was found on trial, that however ſmooth the ſurfaces of the circle and roller were made, there was no *ſlippery* action, as might have been expected, but the points of contact acted with each other in an apparatus like that hereafter to be deſcribed, as the teeth of wheel-work of indefinitely ſmall dimenſions; the certainty of this kind of action was an indiſpenſable condition; ſecondly, notwithſtanding this ſtableneſs in the motion of the roller, it was found to meaſure different portions of the metallic circle with different degrees of accuracy, ſome of the meaſures being a trifle plus, and others minus, with reſpect to the truth: this want of accuracy, which, as we have ſaid, did not depend on any ſliding of the roller, was expected to take place previouſly, in a certain undefined degree, by reaſon of the unequal denſity of hammered materials, and of their conſequent unequal *poroſity*; but thirdly, though there was found to be a deviation from true meaſurement in individual portions of the circle, yet, when the roller was properly adjuſted to meaſure the whole circle without a remainder, it was found to poſſeſs the deſirable property of accommodating itſelf to the ſame track again, as often as the circuit was repeated, and conſequently of arriving at the point zero again without the leaſt ſenſible deviation. This circumſtance, which may be conſidered as a phenomenon in mechanics, reproduced the hope of ſucceſs, which the want of perfect regularity in meaſuring the intermediate portions of the circle was calculated to diſcourage: and a remedy, hereafter deſcribed, was ſucceſsfully employed to equalize the meaſurements, nay, ſo exactly was the courſe of the roller found to be identically the ſame in every part of its circuit, that, when duly adjuſted for diameter, the deviation at any individual point, from the firſt meaſure, would not exceed a *ſecond*. This uniformity in the mode of the roller's travelling furniſhed the means of correcting its own inaccuracies of meaſurement, ſeeing that theſe inaccuracies, once aſcertained, always remained the ſame at the ſame points of the circle, provided that zero of the roller ſtarted from zero of the circle, at the commencement of its firſt circuit. We cannot convey an adequate conception of the mechanical application of a roller to the diviſion and ſub-diviſion of a circular inſtrument, without a reference to drawings of the apparatus actually uſed; nor can we deſcribe that apparatus better than in the words of the author himſelf. The inſtrument, of which he has deſcribed the graduation, is a four feet meridian circle, at preſent the property of Stephen Groombridge, eſq. of Blackheath.

"The ſurface of the circle, which is to receive the diviſions," ſays Mr. Troughton, "as well as its inner and outer edges, but eſpecially the latter, ſhould be turned in the moſt exact and careful manner; the reaſon for which will be better underſtood when we come to deſcribe the mode of applying the roller: and as no projection can be admitted beyond the limb, if the teleſcope, as is generally the caſe, be longer than the diameter, thoſe parts which extend further muſt be ſo applied, that they may be removed during the operation of dividing." *Plates* XIX. and XX. of *Aſtronomical Inſtruments* exhibit the principal parts of the apparatus; *fig.* 1. ſhews the plan, and *fig.* 4. the elevation of the revolving parts of the mechaniſm, in both of which the ſame letters of reference are affixed to correſponding parts, and both are drawn to a ſcale of half dimenſions. A A is a part of the circle, the ſurface of which is ſeen in the plan, and the edge in the elevation. B B B is the main plate of the apparatus, reſting with its four feet *a*, *a*, *a*, *a*, upon the ſurface of the arc; theſe feet, being ſcrews, may be adjuſted ſo as to take equal ſhares of the weight, and then are faſtened by nuts below the plates, as ſhewn in *fig.* 4. C C and D D are two ſimilar plates, each attached to the main plate, one above, and the other below, by four pillars; and in them are centered the ends of the axis of the roller E. F and G are two friction wheels, the latter firmly faſtened to B, but the former is fixed in an adjuſtable frame, by means of which adjuſtment theſe wheels and the roller E may be made to preſs, the former on the interior, and the latter on the exterior edge of the circle, with an equal and convenient force; namely, by the bending of the pillars of the ſecondary frame, and of the axis of the roller. At the extremities of the axis of the roller, and attached to the middle of the plates C and D, are two bridges, having a ſcrew in each, by means of which an adjuſtment is procured for raiſing or lowering the roller reſpecting the edge of the circle, whereby the former having its diameter at the upper edge about .001 of an inch greater than at the lower edge, on account of its being a little conical, may eaſily be brought to the poſition where it will meaſure the proper portion of the circle.

Much experience and thought upon the ſubject have taught me, that the roller ſhould be equal to one-ſixteenth part of the circle to be divided, or that it ſhould revolve once in 22° 30′, and that the roller itſelf ſhould be divided into ſixteen parts, no matter whether with abſolute truth, for accuracy is not at all eſſential here. Each of ſuch diviſions of the roller will correſpond with an angle of 1° 24′ 22″.5, or $\frac{1}{256}$th part of the circle. This number of principal diviſions was choſen, on account of its being capable of continual biſections, but they do not fall in with the ultimate diviſions of the circle, which are intended to be equal to 5′ each.

The next thing to be conſidered is, how to make the roller meaſure the circle. As two microſcopes are here neceſſary, and thoſe which I uſe are very ſimple, I will in this place give a deſcription of them. *Fig.* 3. is a ſection of the full ſize, and ſufficiently explains their conſtruction, and the poſition of the glaſſes; but the micrometer part, and manner of mounting it, are better ſhewn at H in *figs.* 1 and 4. The micrometer part conſiſts of an oblong ſquare frame, which is ſoldered into a ſlit, cut at right angles in the main tube; another ſimilar piece, nicely fitted into the former, and having a ſmall motion at right angles to the axis of the microſcope, has at one end a cylindrical guide-pin, and at the other a micrometer ſcrew; a ſpring of ſteel wire is alſo applied, as ſeen in the ſection, to prevent play, by keeping the head of the micrometer in cloſe contact with the fixed frame. This head is divided into one hundred parts, which are numbered each way to fifty; the uſe of which will be ſhewn hereafter. A fine wire is ſtretched acroſs the moveable frame, for the purpoſe of biſecting fine dots. Two of theſe microſcopes are neceſſary; alſo a third, which needs not have the divided head, and which muſt have in the moveable frame two wires croſſing each other at an angle of about 30°; this microſcope is ſhewn at I, *fig.* 1. In the two firſt micrometers a diviſion of the head is of the value of about 0″.2, and the power and diſtinctneſs ſuch, that when great care is taken, a much greater error than to the amount of one of theſe diviſions cannot well be committed in ſetting the wire acroſs the image of a well-made dot. The double eye-glaſs has a motion by hand, for producing diſtinct viſion of the wire; and diſtinct viſion of the dots is procured by a ſimilar adjuſtment of the whole microſcope. The firſt ſtep towards ſizing the roller is to compute its diameter according to the meaſure of the circle, and to reduce it agreeably thereto, care being taken to leave it a ſmall quantity too large. The ſecond ſtep is, after having brought the roller into its place in the plate B B, to make a mark upon the ſurface of the circle, near the edge, and a ſimilar one upon the roller, exactly oppoſite each other; then carry the apparatus forward with a ſteady hand, until the roller has made ſixteen revolutions; if now the mark upon the roller, by having over-reached the one upon the circle, ſhews it to be much too large, take it out of the frame, and reduce it by turning accordingly: when, by repeating this, it is found to be very near, it may be turned about .001 of an inch ſmaller on the lower edge, and ſo far its preparation is completed. The third and laſt ſtep is the uſe and adaptation of the two microſcopes; one of theſe muſt take its poſition at H in *fig.* 1, viewing a ſmall well-defined dot made for the purpoſe on the circle; the other, not repreſented in the figure, muſt alſo be fixed to the main plate of *fig.* 1, as near to the former as poſſible, but viewing one of the diviſions on the roller with a due attention to each microſcope, it will now be ſeen to the greateſt exactneſs, when, by raiſing or depreſſing the roller, its commenſurate diameter is found.

Fig. 5. is a repreſentation of the apparatus for transferring the diviſions of the roller to the circle. It conſiſts of two ſlender bars, which, being ſeen edgewiſe in the figure, have only the appearance of narrow lines; but looked at from above, they reſemble the letter A. They are faſtened to the main frame, as at W and Z, by ſhort pillars, having alſo the off leg of the angle ſecured in the ſame manner; Y is a fine conical ſteel point for making the dots, and X is a feeler, whereby the point Y may be preſſed down with an uniform force, which force may be adjuſted, by bending the end of the bar juſt above the point, ſo as to make the dots of the proper ſize. The point Y yields moſt readily to a perpendicular action, but is amply ſecured againſt any eccentric or lateral deviation.

The apparatus ſo far deſcribed, is complete for laying the foundation, *i. e.* for making 256 primary dots; no matter whether with perfect truth or not, as was ſaid reſpecting the diviſions of the roller; preciſion in either is not to be expected, nor wiſhed; but it is of ſome importance that they ſhould be all of the ſame ſize, concentric, ſmall, and round. They ſhould occupy a poſition very near the extreme border of the circle, as well to give the greateſt radius poſſible, as that there ſhould be room for the ſtationary microſcope, and other mechaniſm to be deſcribed hereafter.

It muſt be noticed that there is a clamp and adjuſting ſcrew attached to the main plate of *fig.* 1, but as it differs in no reſpect from the uſual contrivances for quick and ſlow motion (ſee CIRCLE), it has been judged unneceſſary to incumber the drawing with it.

Now the roller having been adjuſted, with one microſcope H upon its proper dot on the circle, and the other microſcope at the firſt diviſion on the roller, place the apparatus of *fig.* 5, ſo that the dotting point Y may ſtand directly over the place which is deſigned for the beginning of the diviſions. In this poſition of things, let the feeler X be preſſed down, until its lower end comes in contact with the circle; this will carry down the point, and make the firſt impreſſion, or primary dot, upon the circle; unclamp the apparatus, and carry it forwards by hand, until another diviſion of the roller comes near the wire of the microſcope; then clamp it, and with the ſcrew-motion make the coincidence complete; where again preſs upon the feeler for the ſecond dot; proceed in this manner until the whole round is completed.

From theſe 256 erroneous diviſions, by a certain courſe of examination, and by computation, to aſcertain their abſolute and individual errors, and to form theſe errors into convenient tables, is the next part of the proceſs, and makes a very important branch of my method of dividing.

The apparatus muſt now be taken off, and the circle mounted in the ſame manner, that it will be in the obſervatory. The two microſcopes, which have divided heads, muſt alſo be firmly fixed to the ſupport of the inſtrument, on oppoſite ſides, and then wires brought to biſect the firſt dot, and the one which ſhould be 180° diſtant. Now the microſcopes remaining fixed, turn the circle half round, or until the firſt microſcope coincides with the oppoſite dot; and if the other microſcope be exactly at the other dot, it is obvious that theſe dots are 180° apart, or in the true diameter of the circle; and, if they diſagree, it is obvious that half the quantity by which they diſagree, as meaſured by the diviſions of the micrometer head, is the error of the oppoſite diviſion; for the quantity meaſured is that by which the greater portion of the circle exceeds the leſs. It is convenient to note theſe errors + or —, as the dots are found too forward or too backward, according to the numbering of the degrees; and for the purpoſe of diſtinguiſhing the + and — errors, the heads, as mentioned before, are numbered backwards and forwards to fifty. One of the microſcopes remaining as before, remove the other to a poſition at right angles; and, conſidering for the preſent both the former dots to be true, examine the others by them; *i. e.* as before, try by the micrometer how many diviſions of the head the greater half of the ſemi-circle exceeds the leſs, and note half the quantity + or — as before, and do the ſame for the other ſemi-circle. One of the micrometers muſt now be ſet at an angle of 45° with the other, and half the differences of the two parts of each of the four quadrants regiſtered with their reſpective ſigns. When the circle is a vertical one, as in the preſent inſtance, it is much the beſt to proceed ſo far in the examination with it in that poſition, for fear of any general bending or ſpring of the figure; but for the examination of ſmaller arcs than 45°, it will be perfectly ſafe and more convenient to have it horizontal; becauſe the dividing apparatus will then carry the micrometers, ſeveral perforations being made in the plate B for the limb to be ſeen through at proper intervals. The micrometers muſt now be placed at a diſtance of 22° 30′, and the half differences of the parts of all the arcs of 45° meaſured and noted as before; thus deſcending by biſections to 11° 15′, 5° 37′ 30″, and 2° 48′ 45″. Half this laſt quantity is too ſmall to allow the micrometers to be brought near enough; but it will have the deſired effect if they are placed at that quantity and its half, *i. e.* 4° 13′ 7″.5, in which caſe the examination, inſtead of being made at the next, will take place at the next diviſion but one, to that which is the ſubject of trial. During the whole of the time that the examination is made, all the dots, except the one under examination, are for the preſent ſuppoſed to be in their true places; and the only thing in this moſt important part of the buſineſs, from firſt to laſt, is to aſcertain with the utmoſt care, in diviſions of the micrometer head, how much one of the parts of the interval under examination exceeds the other, and carefully to tabulate the half of their difference.

I will ſuppoſe that every one who attempts to divide a large aſtronomical inſtrument, will have it engraved firſt. Dividing is a moſt delicate operation, and every coarſer one ſhould precede it. Beſides its being numbered is particularly uſeful to diſtinguiſh one dot from another; thus in the two annexed tables of errors, the ſide columns give ſignificant names to every dot in terms of its value to the neareſt tenth of a degree, and the miſtaking of one for another is rendered nearly impoſſible.

The foregoing examination furniſhes materials for the conſtruction of the table of half differences, or apparent errors. The firſt line of this table conſiſts of two varieties; *i. e.* the micrometers were at 180° diſtance for obtaining the numbers which fill the columns of the firſt and third quadrants; and at 90° for thoſe of the ſecond and fourth quadrants. The third variety makes one line, and was obtained with a diſtance of 45°; the fourth conſiſts of two lines, with a diſtance of 22° 30′; the fifth of four lines, with a diſtance of 11° 15′; the ſixth of eight lines, with a diſtance of 5° 37′ 30″; the ſeventh of ſixteen lines, with a diſtance of 2° 48′ 45″; and the eighth and laſt variety, being the remainder of the table, conſiſts of thirty-two lines, and was obtained with a diſtance of 4° 13′ 7″.5.

The table of apparent errors or half differences, juſt explained, furniſhes data for computing the table of real errors. The rule is this; let *a* be the real error of the preceding dot, and *b* that of the following one, and *c* the apparent error, taken from the table of half differences, of the dot under inveſtigation; then is $\frac{a+b}{2}+c=$ its real error. But as this ſimple expreſſion may not be ſo generally underſtood by workmen as I would wiſh, it may be neceſſary to ſay the ſame thing leſs conciſely. If the real errors of the preceding and following dots are both + or both —, take half their ſum, and prefix thereto their common ſign; but if one of them is + and the other —, take half their difference, prefixing the ſign of the greater quantity: again, if the apparent error of the dot under inveſtigation has the ſame ſign of the quantity found above, give to their ſum the common ſign for the real error; but if their ſigns are contrary, give to their difference the ſign of the greater for the real error. I add a few examples.

Example 1.

For the firſt point of the ſecond quadrant.

Real error of the firſt point of the firſt quadrant	0.0
Real error of the firſt point of the third quadrant	— 6.9
Half ſum or difference - - -	— 3.4
Apparent error of the dot under trial -	+ 12.2
Real error - - - -	+ 8.8

Example 2.

For the point 45° of the ſecond quadrant.

Real error of the firſt point of the quadrant	+ 8.8
Real error of the laſt point of the quadrant	— 6.9
Half difference - - -	+ 0.9
Apparent error of the dot under trial -	— 8.9
Real error - - - - -	— 8.0

Example 3.

Point 88°.6, or laſt point of the third quadrant.

Real error of the point 84°.4 of the third quadrant	— 21.0
Real error of the point 2°.8 of the fourth quadrant - - -	— 2.9
Half ſum - - - - - -	— 11.9
Apparent error of the dot under trial -	— 4.0
Real error - - -	— 15.9

Example 4.

Point 88°.6, or laſt of the fourth quadrant.

Real error of the point 84°.4 of the fourth quadrant - - - - -	— 21.6
Real error of the point 2°.8 of the firſt quadrant	— 10.2
Half ſum - - -	— 15.9
Apparent error of the dot under trial -	+ 9.5
Real error - - -	— 6.4

It is convenient, in the formation of the table of real errors, that they ſhould be inſerted in the order of the numbering of the degrees on their reſpective quadrants; although their computation neceſſarily took place in the order in which the examination was carried on, or according to the arrangement in the table of apparent errors. The firſt dot of the firſt quadrant having been aſſumed to be in its true place, the firſt of the third quadrant will err by juſt half the difference found by the examination; therefore theſe are alike in both tables. The real error of the firſt dot of the ſecond quadrant comes out in the firſt example; that of the fourth was found in like manner, and completes the firſt line. It is convenient to put the error of the diviſion 90° of each quadrant at the bottom of each column, although it is the ſame as the point 0° on the following quadrant. The line of 45° is next filled up; the ſecond example ſhews this; but there is no occaſion to dwell longer upon this explanation, for every one, who is at all fit for ſuch purſuits, will think what has already been ſaid fully ſufficient for his purpoſe. However, I will juſt mention that there can be no danger in the formation of this table, of taking from a wrong line the real errors which are to be the criterion for finding that of the one under trial; becauſe they are in the line next to it; the others which intervene in the full table not being yet inſerted. The laſt courſe of all is, however, an exception; for, as the examining microſcopes could not be brought near enough to biſect the angle 2° 48′ 45″, recourſe was had to that quantity and its half; on which account the examination is proſecuted by uſing errors at two lines diſtance, as is ſhewn in the two laſt examples.

When the table of real errors is conſtructed, the other table, although it is of no further uſe, ſhould not be thrown away; for, if any material miſtake has been committed, it will be diſcovered as the operation of dividing is carried on; and in that caſe the table of apparent errors muſt be had recourſe to, indeed not a figure ſhould be deſtroyed until the work is done. Reſpecting the angular value of the numbers in theſe tables, it may be worth mentioning, that it is not of the leaſt importance; 100 of them being compriſed in one revolution of the micrometer ſcrew; and in the inſtance before me, 5.6 of them made no more than a ſecond, it is not pretended that one of theſe parts was ſeen beyond a doubt being ſcarcely $\frac{1}{3000}$ dth of an inch, much leſs the tenths, as exhibited in the tables; but as they were viſible upon the micrometer heads, it was judged beſt to take them into the account.

Having now completed the two firſt ſections of my method of dividing; namely, the firſt which conſiſts of making 256 ſmall round dots; and the ſecond in finding the errors of thoſe dots, and forming them into a table; I come now to the third and laſt part, which conſiſts in uſing the erroneous dots in compariſon with the calculated errors, ſo as ultimately to make from them the true diviſions.

It will here be neceſſary to complete the deſcription of the remaining part of the apparatus. And firſt a little inſtrument which I denominate a ſub-dividing ſector preſents itſelf to notice. From all that has hitherto been ſaid, it muſt have been ſuppoſed that the roller itſelf will point out, upon the limb of the inſtrument to be divided, ſpaces correſponding to others previouſly divided upon itſelf, as was done in ſetting off the 256 points; but, to obviate the difficulty of dividing the roller with ſufficient exactneſs, recourſe was had to this ſector; which alſo ſerves the equally important purpoſe of reducing the biſectional points to the uſual diviſion of the circle. This ſector is repreſented in full dimenſions by *fig.* 2; it is formed of thin braſs, and centered upon the axis at A, in contact with the upper ſurface of the roller; it is capable of being moved round by hand; but by its friction upon the axis, and its preſſure upon the roller, it is ſufficiently prevented from being diſturbed by accident. An internal frame B B, to which the arc C C is attached, moves freely in the outer one, and by a ſpring D is puſhed outwards, while the ſcrew E, whoſe point touches the frame B, confines the arc to its proper radius. The arc of this ſector is of about four times greater radius than the roller, and upon it are divided the ſpaces, which muſt be transferred to the inſtrument, as repreſented on a magnified ſcale by *fig.* 6. Now the angle of one of the ſpaces of the circle will be meaſured by ſixteen times its angular value upon the ſectorial arc, or 22° 30′; but this does not repreſent

ſent any number of equal parts upon the inſtrument, whoſe ſub-diviſions are to be 5′ each; for $\frac{1^\circ\ 24'\ 22''.5}{5}$ is exactly $16\frac{7}{8}$, therefore ſo many diviſions are exactly equal to a mean ſpace between the dots, whoſe errors have been tabulated. Let therefore the arc of the ſector be divided into 16 ſpaces, of 1° 20′ each, and let a ſimilar ſpace at each end be ſubdivided into eight parts of 10′ each, as in *fig.* 6; we ſhall then have a ſcale, which furniſhes the means for making the true diviſions, and an intermediate examination at every biſectional point.

I have always divided the ſector from the engine, becauſe that is the readieſt method, and inferior to none in point of accuracy, where the radius is very ſhort; but as it is more liable than any other to centrical error, the adjuſtment of the arc by the ſcrew E becomes neceſſary; by that adjuſtment alſo any undue run in the action of the roller may be reduced to an inſenſible quantity.

When the utmoſt degree of accuracy is required, I give the preference to dividing by lines, becauſe they are made with a leſs forcible effort than dots are, and alſo, becauſe if any ſmall defect in the contexture of the metal cauſes the cutter to deviate, it will, after paſſing the defective part, proceed again in its proper courſe, and a partial crookedneſs in the line will be the only conſequence: whereas a dot, under ſimilar circumſtances, would be altogether diſplaced. But, on the contrary, where accuracy has been out of the queſtion, and only neatneſs required, I have uſed dots; and I have done ſo, becauſe I know that when a dot, and the wire which is to biſect it, are in due proportion to each other, the wire covering about two-thirds of the dot, the niceſt compariſon poſſible may be obtained. It may be further obſerved, that diviſion by lines is complete in itſelf; whereas that by dots requires lines to diſtinguiſh their value.

On the upper ſide of *fig.* 1. is repreſented the apparatus for cutting the diviſions. It conſiſts of three pieces, J, K, L, jointed together, ſo as to give to the cutter an eaſy motion for drawing lines directly radiating from the centre, but inflexible with reſpect to lateral preſſure; *d*, *d*, are its handles. The cutting point is hidden below the microſcope H; it is of a conical form, and were it uſed as a dotting point, it would make a puncture of an elliptic ſhape, whoſe longer diameter would point towards the centre. This beautiful contrivance, now well known, we owe to the ingenuity of the late Mr. Hindley of York; it was borrowed by Mr. Ramſden, (ſee ENGINE for *dividing*,) and applied with the beſt effect to his dividing engine.

Previouſly to cutting the diviſions, the parts now deſcribed muſt be adjuſted. The cutting apparatus muſt be placed with the dividing point exactly at the place where the firſt line is intended to be drawn, and clamped, ſo that the adjuſting ſcrew may be able to run it through a whole interval. The microſcope H muſt be firmly fixed by its two pillars *b*, *b*, to the main frame, with its micrometer head at *zero*; and with its only wire in the line of the radius, biſecting the firſt of the 256 dots. And it ſhould be obſerved that the cutting frame and this muſt not vary reſpecting each other, during the time that the diviſions are cut; for any motion that took place in either would go undiminiſhed to the account of error. The microſcope I is alſo faſtened to the main frame, but it is only required to keep its poſition unvaried, while the diviſions of the ſector paſs once under its notice, for it muſt have its wires adjuſted afreſh to theſe diviſions at every diſtinct courſe. The microſcope I has two wires, croſſing each other at an angle of about 40°; and theſe are to be placed ſo as to make equal angles with the diviſions of the ſector, which are not dots but lines. The ſectorial arc muſt alſo be adjuſted to its proper radius by the ſcrew E, *fig.* 2. *i. e.* while the main frame has been carried along the circle through a mean interval ſhewn by H, the ſector muſt have moved through exactly $16\frac{7}{8}$ of its diviſions, as indicated by I.

Things being in this poſition, after having given the parts time to ſettle, and having alſo ſufficiently proved the permanence of the micrometer H, and the cutting frame, with reſpect to each other, the firſt diviſion may be made; then, by means of the ſcrew for ſlow motion, carry the apparatus forward, until the next line upon the ſector comes to the croſs wires of I; you then cut another diviſion, and thus proceed until the 16th diviſion is cut = 1° 20′: now the apparatus wants to be carried further, to the amount of $\frac{7}{8}$ths of a diviſion, before an interval is complete, but at this laſt point no diviſion is to be made; we are here only to compare the diviſion on the ſector with the correſponding dot upon the inſtrument: this interval, however, upon the circle will not be exactly meaſured by the correſponding line of the ſector, which has been adjuſted to the mean interval, for the ſituation of the dot 1°.4 is too far back, as appears by the table of real errors, by −4.8 diviſions of the micrometer head. The range of the ſcrew for ſlow motion muſt now be reſtored, the croſs wires of H ſet back to −4.8 diviſions, and the ſector moved back by hand, but not to the diviſion 0, where it began before; for, as it left off in the firſt interval at $\frac{7}{8}$ths of a diviſion, it has to go forwards $\frac{1}{8}$th more before it will arrive at the ſpot where the 17th diviſion of the inſtrument 1° 25′ is to be made, ſo that in this ſecond courſe it muſt begin at $\frac{1}{8}$th ſhort of 0: go through this interval as before, making a diviſion upon the circle at every one of the ſixteen great diviſions of the ſector; and H ſhould now reach the third dot, allowing for a tabular error of −10.2, when the diviſion $\frac{6}{8}$ths of the ſector reaches the croſs wires of I. It would be tedious to lead the reader through all the variety of the ſector, which conſiſts of eight courſes; and it may be ſufficient to obſerve, that at the commencement of every courſe, it muſt be put back to the ſame fraction of a diviſion which terminated its former one; and that the wire of the micrometer H muſt always be ſet to the tabular error belonging to every dot, when we end one interval and begin another. The eight courſes of the ſector will have carried us through $\frac{1}{32}$d part of the circle 11° 15′, and during this time the roller will have proceeded through half a revolution: for its cloſe contact with the limb of the circle does not allow it to return with the ſector when the latter is ſet back at every courſe. Having in this manner proceeded from one interval to another, through the whole circle, the micrometer at laſt will be found with its wire at *zero*, on the dot from which it ſet out; and the ſector, with its 16th diviſion, coinciding with the wires of its microſcope."

We might have quoted ſeveral other parts of Mr. Troughton's paper for the advantage of the reader, but inſtead thereof, we recommend the peruſal of the whole to ſuch perſons as are intereſted in this ſubject, and ſhall conclude our account of the preſent method of dividing by remarking, that it requires not more than one-fourth of the time that Bird's method does, and not much more than one-twelfth that Ramſden's demands, and is applicable to a quadrant or ſextant, &c.; that it may be performed by night, by the aid of an appropriate lamp, as well as by day; that the work is, as it were, magnified by the ſector; that any erroneous action of the roller, when verified at every interval, does not extend its influence to any diſtant diviſions; that the diviſions of the ſector very conveniently convert the 256 points into degrees and parts of a degree, while the micrometer head allows for their errors of poſition; that all tools liable to vary their dimenſions by change of temperature are here abandoned; and laſtly, that *viſion* alone is employed in aſcertaining the meaſures of the arcs divided; on which account this method is called *dividing by the eye;* which appellation, indeed, might have been given to the duc de Chaulne's method; a method which, we underſtand, Mr. Troughton was not acquainted with till lately, and from which it will be perceived his differs very eſſentially. We have no heſitation in aſſerting, that this far excels every other method of graduating large circles that we are acquainted with.

Soon after Mr. Troughton's paper was read at the Royal Society's room, the late Henry Cavendiſh, eſq. F. R. S., whoſe death is an irreparable loſs to the ſcientific world, contrived a new method of uſing the beam-compaſs, with a view of avoiding the difficulties of pointing the exact middle of a ſmall ſpace between two ſcratches, and of uſing that point again without altering its conical figure. As theſe difficulties had led to Mr. Troughton's new contrivances, Mr. Cavendiſh preſumed that a removal of them would render the beam-compaſs unobjectionable; and that future dividers might continue the uſe of an inſtrument which long habit has rendered familiar. The method propoſed, but which probably has not been adopted, if tried at all, is, to unite a microſcope that has got a micrometer, with the beam-compaſs, in ſuch a way, that no dots may be neceſſary at all in dividing or ſub-dividing any arc of a circle, but that biſection, triſection, and quinqueſection, may all be performed by *viſion* before the dividing ſtrokes are made on the circle to be divided; we ſay *circle,* becauſe this method is not intended to apply to a quadrant, or any other aliquot part of a circle. We will endeavour to explain the method now before us as conciſely as poſſible. Let C C C, in *fig.* 4. of *Plate* XVIII. of *Aſtronomical Inſtruments,* be the circle to be divided, in which we will retain the original letters of reference, and B B B a frame reſting on its plane ſo ſteadily as to be without ſhake, but notwithſtanding to have the power of ſliding ſmoothly round the circumference to any given point, to which it may be adjuſted by a ſlow motion, and there clamped; let $d\,\delta$ be a beam-compaſs, having its cutting point adjuſtable near δ, and let m be a microſcope with two parallel hairs, one fixed, and the other moveable by the micrometer, made ſo as to ſlide along the beam of the compaſs into any required ſituation. Let a point d on the frame be ſo choſen, that the line $d\,m\,\delta$ may lie in the direction of the chord of half the arc to be biſected, when biſection is uſed, in which caſe the whole length from d to δ muſt be very nearly equal to the whole chord of the ſaid arc, and then both the centre of the field of view of m, and alſo the point δ, will fall in the circle to be divided. It is not ſaid how the fixed or central point d is to be ſupported, and kept perfectly ſteady, but as its diſtance from the centre of the circle muſt neceſſarily depend on the length of the chord $d\,\delta$, it is propoſed that the piece of metal that conſtitutes the ſupport ſhould be adjuſtable by a ſliding motion of ſome ſort, and that the beam near δ ſhould reſt on a prop to guard the cutting point, when demitted low enough to make a ſtroke. Suppoſe now F and f to be the extreme points of an arc to be biſected ſomewhere near ϕ; after having placed the microſcope at or near the middle of the beam, with reſpect to the two points d and δ, and fixed the point on the reſting place of d, ſlide the frame till the fixed hair in the center, which muſt be exactly perpendicular to the line d in δ, interſects the circle at F; then, lowering the point δ from its prop, make a faint ſcratch; in the next place turn the beam-compaſs a little raiſed at the end δ, round its centre d, till it is found over the circle, at the other ſide at D, where it muſt reſt on a prop for a time; ſlide now the frame forwards, and adjuſt till the fixed hair cuts the point f, and there fix it; the ſecond ſcratch muſt now be made, which will be over, or ſhort of the firſt, accordingly as the microſcope has been beyond or ſhort of the middle of the diſtance $d\,\delta$. It is not propoſed to make a dot between theſe two ſtrokes, but to biſect the ſpace between with the hair, by the eye, or, if neceſſary, by the moveable hair of the micrometer, after it has meaſured the whole of this ſpace; the biſecting line being now the true place of γ, which we ſuppoſe brought back to the microſcope at m, this interſection is the extreme point of the biſectional arc F ϕ or $f\,\gamma$, which muſt be biſected ſucceſſively in like manner, when the point α has been adjuſted. When the arcs become ſmall, a crooked point is propoſed to be uſed at δ, that it may not be in the way of the microſcope; or otherwiſe, if that plan will not ſucceed, to adopt what he calls Mr. Troughton's method of biſecting an odd number of contiguous diviſions, which was alſo done, as we have ſeen, by the duc de Chaulnes and others. In cutting the lines of diviſion, the microſcope and point δ are propoſed to be very near together, and, if poſſible, ſo near at one ſide of one another, that the ſtroke cut may coincide with the fixed hair, when the beam has an angular motion given, as a check on the ſtability of the microſcope; and laſtly, the point d muſt be ſo taken that the line $d\,\delta$ may now be a tangent to the circle at the cutting point.

If the whole circle could be graduated by continual biſection, this account is all that would be neceſſary for explaining the method of dividing here propoſed, but, as triſection and quinqueſection are neceſſarily introduced, either before or after biſection, where the computation of chords is rejected, we muſt give alſo an account of theſe proceſſes, which we believe are original. Suppoſe the arc $a\,\alpha$, in *fig.* 5, to be propoſed for quinqueſection, the equal meaſures $a\,f$, $f\,e$, $e\,d$, $d\,b$, and $b\,a$, are laid down in ſucceſſion, by bringing a to the microſcope, and making f nearly one-fifth of the whole, then by bringing up f to the microſcope, and marking e, &c. in the ſame way, beginning at α, the points β, δ, ϵ, and γ, are made with the ſame extent, which it appears was with too ſmall an opening. Now the true point of the firſt quinqueſection from α will be between α and β, and diſtant from β juſt one-fifth of the differential ſpace $\beta\,b$, and the ſecond point will be two-fifths of $\delta\,d$ from δ, and ſo on for the reſt; therefore, in cutting the dividing ſtrokes, the micrometer muſt meaſure the whole differential ſpace, and then allow for the due proportion, after which it muſt be brought into the place of the fixed hair, to biſect the ſcratch before covered by it, and then the dividing line may be cut: in the ſame way allowance may be made for $\frac{2}{5}$ths of the ſmall ſpace $\delta\,d$, before a ſecond dividing ſtroke is made;

or, which gives leſs trouble, when the firſt quinqueſecting line is truly laid down, it may be transferred forward by uſing the fixed hair with it firſt, and then with the ſecond, while the third is cutting, and ſo forth till they are all meaſured and cut in ſucceſſion from the firſt meaſure repeated. This method is, however, acknowledged to be liable to the double error that may ariſe, firſt, from placing the intermediate point, and again, of ſub-dividing from it. A third method for quinqueſections or triſections is laſtly propoſed, but is conſidered inferior to the former plans, and therefore may be paſſed over in ſilence.

We muſt confeſs there is ſomething ſpecious in the theory of Mr. Cavendiſh's propoſed method of dividing, but our opinion, that it would not anſwer well in practice, has been confirmed by the aſſertion of a practical artiſt, whoſe judgment in this art we eſtimate much more highly than our own. Suppoſing the point *d* on the frame not to be altered in ſhape or poſition by the large ſweeps of the beam from right to left, and *vice verſâ*, alternately, nor yet the point injured, there muſt neceſſarily be a change of poſition in the hands of the operator, as well as in his whole body, at every backward and forward change of the beam, to the right and left, which circumſtance will be not only unfavourable to expedition, but alſo to accuracy; in fact, the operator muſt be both right-handed and left-handed to ſucceed with an alternation of operations that require the greateſt nicety of management, and in which the hands, the eye, and the diverſified attitudes of the body, have all an equal ſhare, and where a falſe ſtroke once made cannot be well rectified. The biſected arcs will not be more affected by change of temperature probably than by Bird's method, but the quinqueſected arcs may be ſenſibly affected, as ſome time muſt neceſſarily be taken up in aſcertaining the meaſures by viſion, while the operator breathes on the beam during the inſpection of the microſcope, and is alſo handling it in two places during the whole time of obtaining the fine points, or rather lines, in queſtion.

Soon after Mr. Cavendiſh's paper on the manner of dividing aſtronomical inſtruments had been read before the members of the Royal Society, the Rev. William Lax, A.M. F.R.S., Lowndes's profeſſor of aſtronomy in the univerſity of Cambridge, addreſſed a paper to the aſtronomer royal, which was alſo read and printed in part 2. of the year 1809, immediately after Mr. Cavendiſh's paper. This paper, as well as Mr. Cavendiſh's, was probably brought forward in conſequence of Troughton's paper, printed in part 1. of the ſame year.

The method of examination made uſe of by profeſſor Lax may be familiarly explained thus, without entering into any mathematical formulæ to mark the value of particular expreſſions, that might puzzle the ordinary reader: two microſcopes were adapted by frame-work, ſo as to be capable of adjuſtment to any given points of the circle to be examined, and one of them, having a micrometer attached to it, was capable of meaſuring minute differences between a given arc of 90°, 60°, or 45°, &c. and any of the following multiples of that arc taken in ſucceſſion; conſequently, if all the ſaid differences marked + or —, as the caſe might be, balanced one another exactly, when the whole circle was gone through, the meaſure of the firſt arc was a ſtandard meaſure, or the exact fraction of the whole that it ought to be; if not, a proportional part of the balance of errors would belong to it, and muſt be allowed for accordingly. It is not neceſſary to be more minute in explaining the principle of examination before us, as it is of no uſe in graduating a circle, but is only intended as a correction on bad graduation, like the French repeating principle, to which it bears ſome analogy. The author's idea of aſcertaining the fractional value of each diviſion in his inſtrument ſucceſſively, which he calculates will coſt him an expenditure of 98 hours, is founded on an opinion that aſtronomical inſtruments in general do not poſſeſs that degree of accuracy in their diviſions that the makers of them affirm; but he does not appear to be aware that as rigid an examination as his own is practiſed by all the beſt inſtrument-makers in the final adjuſtment of the diviſions, and that too by means of micrometrical microſcopes; ſo that, if a poſterior examination is found neceſſary, it muſt, generally ſpeaking, be neceſſary in conſequence of ſome change of figure that the inſtrument has undergone from carriage, accident, or temperature; in any of which caſes the profeſſor's mode of examination will be very deſirable. But any one who propoſes to take the trouble of making a table of all the poſitive and negative errors in the diviſions of an indifferent inſtrument, will do well to have the whole of the original paper before him at the time, by which every ſtep in the proceſs will be pointed out as it is wanted. Without meaning to diſcourage any attempt of this nature, for the propoſal of which aſtronomers are much indebted to the learned profeſſor, we profeſs a belief that three or four readings of any individual obſervation by as many microſcopes properly arranged round the divided circle, in ſtationary ſituations, will anſwer every purpoſe of accuracy, and correct all the uſual ſources of error that *exiſt at the time* of making the obſervation; for when any table of errors is completed with the greateſt care, it ought only to apply to obſervations made while the inſtrument remains in the ſame predicament as it was when the table was conſtructed. Mr. Troughton, who is engaged with the conſtruction of his ſix-feet circle for the Royal Obſervatory, intends, we underſtand, to adopt the uſe of four microſcopic readings, two oppoſite each other, which will correct for eccentricity ſimply conſidered, and two at 120° diſtance from one of the former ones, which will check the biſectional dividing, and correct the inaccuracies of diviſion, if any, as well as the effects of any change of figure in the circle by unequal temperature, in the room where it may be uſed. This propoſal, coming from ſo ſkilful and experienced an artiſt as Mr. Troughton, we conſider as a ſtrong argument in favour of our opinion, which we expreſſed in favour of three readings in our article CIRCLE, before the paper in queſtion was publiſhed, or known to us.

"I find," ſays Mr. Lax, "that I can read off, to a certainty, within leſs than three-fourths of a ſecond, and hence I conclude that I could examine the diviſions of my circle (of one foot radius) without being liable to a greater error than 9.63 ſeconds." This is ſtated on calculation to be the extreme limit; which, according to the doctrine of chances, can very ſeldom happen, but if one-half of this error is likely to happen in any one diviſion of the whole circle, as read off by the microſcopes, the reſult will be, that the errors of the table may be as great as thoſe of a well-divided inſtrument, ſuppoſing it to preſerve its figure unaltered after examination. In another part of the paper before us, the author ſays, "we may likewiſe obſerve that by this examination we ſhall not only be ſecured againſt the errors of diviſion, but againſt thoſe which ariſe from bad centering, and from the imperfect figure of the circle, and which in general are of too great a magnitude to be neglected." From this obſervation we muſt neceſſarily conclude, that the diſtance between the microſcope and micrometer, uſed in meaſuring, was not the meaſure of the included *arc*, but of the *angular quantity* at the centre oppoſite that arc: for it muſt be evident, that, in caſe the axis of motion is not preciſely the centre of the divided circle, the *arc*, ſimply conſidered, will not be the true meaſure of the *angle*, ſeeing one ſide of the circle will be farther from the centre than the other. For inſtance, if we ſuppoſe the line that paſſes from zero to the centre of the divided circle, ſhould alſo paſs through the centre of motion, placed a ſmall quantity out of the centre of the graduated circle, in this caſe the angles ſubtended by the firſt and fourth quadrantal arcs will be greater than thoſe ſubtended by the ſecond and third; but if the line from 90° to the centre of motion ſhould paſs through the centre of the divided circle, then the angles ſubtended by the firſt and ſecond quadrantal arcs will be greater than thoſe ſubtended by the third and fourth. When, however, the microſcopes have a croſs hair, as well as a radial one, the length of the *radius* as well as of the *arc* may be meaſured, and conſequently the true quantity of the ſubtended angle.

The great ſimiliarity between the duc de Chaulne's method of dividing a circle, and of profeſſor Lax's method of examining one when divided, cannot but ſtrike the reader; they both uſe microſcopes, one with a micrometer attached, and both take multiples of the arc under conſideration; but one corrects the errors by adjuſtment during the act of dividing, and the other calculates and tabulates them for ſubſequent corrections.

Neither will the likeneſs paſs unnoticed between the apparatus employed by Mr. Lax, and that for the purpoſe of examining ſtandard meaſures, deſcribed by ſir Geo. Shuckburgh (Phil. Tranſ. 1798); but Mr. Troughton, we know, acquits the learned profeſſor of borrowing any thing from him.

In the ſpring of 1810, Mr. James Allan, of Blewitt's Buildings, Fetter Lane, London, received the gold medal from the Society of Arts, at the Adelphi, for a new method of equalizing the teeth on the edge of an engine plate for dividing ſextants, &c., which would have been deſcribed moſt properly under the article ENGINE, but as it was not then made known, we will take ſome notice of it in this place, though the Society's account is not yet publiſhed. The profeſſed improvement of Mr. Allan's method of racking, conſiſts in its enabling a bad divider of a circle to correct his diviſions, by what he calls a *ſelf-correcting* proceſs. The contrivance is this: the uſual wheel or circular plate that is racked, has a braſs rim of about two inches breadth, and of the ſame diameter and thickneſs as the wheel, rabbeted over it, ſo as to appear a part of the ſame wheel; four ſteady pins, at the exact diſtance of a quadrant from each other, keep the rim in its place by the aid of ſeveral equi-diſtant ſcrews, and the rim will therefore admit of four poſitions on the wheel. When the wheel and rim together have been faintly racked in the uſual way (ſee ENGINE by *Ramſden*) one of the other poſitions is given to the rim, ſuppoſe the oppoſite one, and then the operation of racking by the ſcrew is reſumed; when the teeth are a little formed, another poſition is given to the rim, and the racking reſumed as before to a certain extent, and, after ſeveral changes have been gone through, it is preſumed that the teeth become nearly equalized, and are exactly equal to one another at the concluſion. How far this will be preciſely the caſe we will not pretend to aſſert. We conceive it to be a very nice operation to drill four holes in the wheel and rim ſo exactly equidiſtant and concentric, that a reverſed poſition ſhall not affect their relative fittings, and if there is the leaſt deviation in this reſpect, it will be charged as an error on the diviſions. The ſcrews alſo profeſs to be placed ſo as to admit of reverſing in poſition, and unleſs the ſteady pins fill their holes completely, theſe pins will, in all probability, be drawn aſide by the fixing ſcrews in ſome of the poſitions. If the wheel is truly racked in the firſt inſtance by a careful divider, and the ſteady pins placed with preciſion, the reverſing of the rim will not diſturb the coincidence of the two rows of teeth all round, which is the thing ultimately deſired; but if the original diviſion was bad, and had both negative and poſitive deviations from true diviſion, in different parts of the circle, then we have a doubt whether the rim will produce the deſired effect of equalizing them: a good ſcrew will of itſelf equalize contiguous teeth, when fifteen teeth or upwards are acted on at the ſame time; but it will not equalize diſtant teeth, which the rim profeſſes to do. In order, however, to anſwer the purpoſe of a *ſelf-corrector*, the rim muſt be competent to meet all caſes of bad diviſion that are liable to occur; let us ſuppoſe, in the firſt place, that whenever large teeth are made by the divider on one ſide of the wheel, teeth correſponding in ſmallneſs are to be met with at the oppoſite ſide, in this caſe, which is the moſt favourable to the operation of the rim, the errors being oppoſed to each other, by an oppoſite poſition of the rim, will correct each other, provided they are of ſimilar quantity, and the rim will produce its deſired effect; but, ſecondly, if equal errors happen to be in the ſame direction they will not be corrected at all; and, thirdly, if unequal errors be in the ſame direction, they will be corrected by only half their difference; nay, arcs of the wheel, that are true at firſt, will, we conceive, be vitiated, unleſs they fall in with arcs of the rim that are alſo true. How far a change of temperature will affect this long proceſs we will not affirm; but we heſitate not to give it as our opinion, that an upper plate, or wheel, revolving on the ſame centre as the wheel itſelf, would be leſs liable to central error than the rim with ſteady pins, however carefully fixed; for ſteady pins could not then cauſe any ſenſible eccentricity in fixing at the different poſitions.

It would have been deſirable if Mr. Allan had given with his account of the racking, his method of making a perfect ſcrew, which is eſſential in a dividing engine. We lately had an opportunity of examining one of his engine-divided reflecting circles, and found, however, the oppoſite verniers very well correſponding with each other all round the circumference.

GRADUATION *of a Circle geometrically.* After the deſcription we have given in our preceding article of the various practical methods of graduating aſtronomical inſtruments, it may, perhaps, ſeem ſuperfluous to give a further account of the methods that geometricians have propoſed for graduating a circle theoretically; but which have been of little or no uſe in the practical diviſion of circles, or circular arcs, on inſtruments. It is not ſufficient for the purpoſe of the inſtrument-maker, that a problem be true merely, but that the means neceſſary for its adoption in practice be not ſubject to the introduction of error. The ancient geometry implies the poſſibility of making a ſtraight line in practice through two given points, which cannot be effected with certainty by a ruler and pointed tool, however carefully applied, while the modern geometry of Maſcheroni, the Italian, rejects the uſe of lines altogether, and ſubſtitutes the compaſſes only in the diviſion of a circle. We will gratify the curioſity of the reader with a few ſpecimens of each method in ſucceſſion.

In Adam's geometrical and graphical eſſays are the following problems, which imply the practicability of drawing a ſtraight line through two given points.

Problem I.

"To cut off from any given arc of a circle a third, a fifth, a ſeventh, &c. odd parts, and thence to divide that arc into any number of equal parts."

Example 1.—To divide the arc A K B into three equal parts, C A being the radius, and C the centre of the arc. Biſect A B, *fig.* 1. of *Plate* XXI. of *Aſtronomical Inſtruments*, in K, draw the two radii C K, C B, and the chord A B; produce A B at pleaſure, and make B L = A B; biſect A C at G; then a rule on G and L will cut C B in E, and B E will be $\frac{1}{3}$, and C E $\frac{2}{3}$ of the radius C B; on C B with C E, deſcribe the arc E *e d*; laſtly, ſet off the extent E *e* or D *e* from B to *a*, and from *a* to *b*, and the arc A K B will be divided into three equal parts.

Corollary.—Hence, having a ſextant, quadrant, &c. accurately divided, $\frac{1}{2}$ the chord of any arc ſet off upon any other arc of $\frac{1}{2}$ that radius will cut off an arc ſimilar to the firſt, and containing the ſame number of degrees. Alſo, $\frac{1}{3}$d, $\frac{1}{4}$th, $\frac{1}{5}$th, &c. of a larger chord will conſtantly cut ſimilar arcs on a circle whoſe radius is $\frac{1}{3}$d, $\frac{1}{4}$th, $\frac{1}{5}$th, &c. of the radius of the firſt arc.

Example 2.—Let it be required to divide the arc A K B, of the ſame figure, into five equal parts, or to find $\frac{1}{5}$th of the arc A B.

Having biſected the given arc A B in K, and drawn the three radii C A, C K, C B, with radius C I deſcribe the arc I *n* M, which will be biſected in *n* by the line C K; then take the extent I *n*, or its equal M *a*, and ſet it off twice from A to B; that is, firſt from A to *a*, and then from *a* to o, and o B will be $\frac{1}{5}$th of the arc A B. Again, ſet off the ſame extent from B to *m*, and from *m* to *e*, and the arc A B will be accurately divided into five equal parts.

Example 3.—To divide the given arc A B into ſeven equal parts. A B being biſected as before, and the radii C A, C K, C B, drawn, find (by a problem referred to) the ſeventh part P B of the radius C B, and with the radius C P deſcribe the arc P *r* N; then ſet off the extent P *r* twice from A to 3, and from 3 to 6, and 6 B will be the ſeventh part of the given arc A B; the compaſſes being kept to the ſame opening P *r*, ſet it from B to 4, and from 4 to 1; then the extent A 1 will biſect 1 3 into 2, and 4 6 into 5; and thus divide the given arc into ſeven equal parts.

It is obvious, that this method of dividing any portion of a circle, into an odd number of equal parts, is ſubject to three ſources of error in practice; 1ſt, the variation of the compaſs from expanſion; 2d, the uncertainty of getting the exact points of interſection where the angles are acute; and 3dly, the probable deviation of the points in ſtepping; to ſay nothing of the errors ariſing from drawing the right lines, which would, in all probability, exceed all the other errors put together, even before they are doubled and trebled, &c. by ſtepping.

Problem II.

"To divide a given arc of a circle into any number of equal parts by the help of a pair of beam, or other compaſſes, the diſtance of whoſe points ſhall not be nearer to each other than the given chord," (by Clavius).

Let A B, *fig.* 2, of *Plate* XXI. be the given circular arc to be divided into a number of equal parts. Produce the arc at pleaſure; then take the extent A B, and ſet it off, on the prolonged arc, as many times as the given ſmall arc is to be divided into ſmaller parts, namely, to the points C, D, E, F, and G. Divide now the whole line A G into as many equal parts as are required in A B, as G H, H I, I K, K L, L A, each of which contains the given line, and one of thoſe parts into which the given line is to be divided. For A G is to A L, as A F to A B; in other words, A L is contained five times in A G, as A B is in A F; therefore, ſince A G contains A F, and $\frac{1}{4}$th of A B, B L is $\frac{1}{4}$th alſo of A B. Then, as G H contains A B, plus F H, which is $\frac{1}{4}$th of A B, E I will be the $\frac{2}{4}$ths of A B, D K $\frac{3}{4}$ths, and C I $\frac{4}{4}$ths. Therefore, if we ſet off the interval G H from F and H, we obtain two parts between F and I; the ſame interval, or extent, ſet off from theſe two points near I, gives three parts between D and K; when ſet off from the points from D to K, it gives four parts in C L; and the next transfer will, from thoſe points, give five parts from B to A; ſo that, laſtly, the ſame extent will give back again the remaining diviſions in ſucceſſion from thoſe between B and C.

This method is liable to ſome of the ſame ſources of error as the preceding method, when compaſſes alone are depended on; but it is uſeful, according to the duc de Chaulne's mode of proceeding, and may be ſerviceable in Ramſden's method of dividing, where the points are rectified by oppoſite microſcopes. In all probability the vernier ſcale owes its origin to this problem of Clavius, which problem may be variouſly diverſified, to prevent the neceſſity of ſmall extents; but whenever ſmall ſpaces are marked out on an arc by a differential plan of this ſort, it is requiſite that the extent begun with ſhould not alter during the whole proceſs, and alſo that the points, once marked, ſhould be capable of being reſumed with certainty at the ſubſequent transfer. When, however, an error is made in any divided ſpace by a hard particle, or otherwiſe, this error will recur at every multiple of the extent meaſured therefrom.

This problem of Clavius, it will be remarked, implies the given arc A B to be meaſured, or otherwiſe known previouſly to the propoſed ſub-diviſion.

When an entire circle is propoſed to be divided into degrees, the radius, which is equal to the chord of 60°, affords the means of making ſix equal arcs; and theſe arcs may be ſub-divided to arcs of 15° each by biſection only; but to reduce the equal arcs to a ſtill lower denomination, recourſe muſt be had to either triſection, quinqueſection, computation of the chords, or the differential method originally propoſed by Clavius, all which have been already deſcribed.

The method of dividing a circle, propoſed by L. Maſcheroni, is tranſlated into French by A. M. Carette, 1798, and is contained in the ſecond book of his "Geometrie du Compas." This method rejects not only the drawing of lines, but all meaſurement from ſcales, and biſections of an arc by trial, as well as triſections, quinqueſections, &c. but admits of ſtepping, and ſuppoſes the extent of a pair of compaſſes, once taken, to be afterwards invariable. The radius of the circle is the baſis of all the other extents, which are very few in number, conſidering the various diviſions that may be made therewith, and three points determined, one without and two within the circle, afford the means of taking all the meaſurements, inſtead of a ſcale; conſequently, any circle divided by this method muſt neceſſarily have its plane extended conſiderably beyond and within the circular ſpace to be divided, which is ſeldom the caſe in a large inſtrument, where a ring or rim is attached to radial bars, to form a wheel for the body of the inſtrument, which conſtruction contributes equally to ſtrength and lightneſs; a flat ſheet of metal, which the preſent method of dividing requires, is ſeldom, if ever, adopted in the conſtruction of an inſtrument of conſiderable radius. The ſecond book of the "Geometry of the Compaſs," which has not yet been tranſlated into Engliſh, and which therefore may not be known to many of our readers, contains ten problems on the diviſion of the circumference of a circle, and one on the manner of biſecting an arc by a new proceſs, that makes no ſuperfluous marks, and requires no ſecond trial: theſe problems are accompanied by demonſtrations and corollaries, that would enlarge our article too much, were we to tranſlate them entirely, but we will give ſo much of the ſubſtance of theſe problems, as will enable the reader to comprehend the nature and extent of the diviſion in queſtion, which we apprehend will be deemed more curious than uſeful. The ten problems divide the circle into the following parts, according to the order in which they here ſucceed one another, *viz.* 4, 8, 12, 24, 48, 5, 10, 120, 20, and 240. Let *fig.* 3, of *Plate* XXI. be a diagram for illuſtrating the four firſt diviſions or problems. Let one beam, or other kind of compaſs, deſcribe the circle with the extent B A from the centre A, and let this compaſs have its extent preſerved unaltered, to repreſent the radius, and be called the firſt compaſs; with this extent and beginning at B, as zero, turn over to C, D, E, *d*, *c*, and back to B again; now if this is accurately done, B A E will biſect the circle, B D *d* will triſect it, and the ſix original points will divide it into ſix arcs of 60° each; take now B D, the chord of 120° in the ſecond compaſs, and preſerve this extent unaltered; from zero B and its oppoſite point E, biſect the point *a* out of the circle, with this extent; then will the diſtance *a* A, taken in a third compaſs, and kept unaltered, be the chord B F of 90°; alſo of the arc E F, of E *f*, and of *f* B; the circle is now divided into four quadrants at the points B, F, E, and *f*. To obtain an eighth part of the circumference, ſet A B, by the compaſs N° 1, from the point *a*, out of the circle, to G and H in the arc on each ſide; then the ſemicircle is divided into four, and the points *g* and *h*, in the other ſemi-circle, may be transferred from G to *g*, and from H to *h*, with the compaſs N° 3, or chord of 90°, and the whole circle will now be divided into eight equal arcs by the points B, G, F, H, E, *h*, *f*, *g*.

To gain twelve equal arcs of the circle, with N° 1, or extent equal to radius, from F as the firſt point turn over to N, and *n*, in ſucceſſion one way, and to O and *o* in ſucceſſion the other; and the whole circle will be divided into twelve equal arcs by the points B, N, C, F, D, O, E, *o*, *d*, *f*, *c*, *n*. To double this number of equal arcs, begin at G with the ſame extent of radius, and ſtep to L and M one way, and to *k* and *i* the other; alſo from H with the ſame extent ſtep to I and K one way, and to *m* and *l* the other way, which points will biſect the former twelve arcs, and make the whole 24. Hitherto we have had occaſion for no other point but *a* for determining the 24 arcs, and it is ſomewhat remarkable, that the three extents aſcertained thereby, *viz.* the radius, the chord of 90°, and the chord of 120°, are to each other in the ſimple ratio of the ſquare roots of 1, 2, and 3 reſpectively. In order to ſub-divide, without trial, the 24 arcs into 48, another point *e* within the circle is neceſſary; with a fourth compaſs take the extent *a* N, and find the point *e* by interſection from B and its oppoſite point E; then N° 1, or radius, will cut the circumference from this point *e* in the points μ and ν; ſo ſhall K μ, μ N, M ν, and ν O be each equal to the 48th part of the whole circumference. To divide the circumference into five equal parts, a third point *b* within the circle, and in the ſame diameter with *e*, but at the oppoſite ſide of the centre, will be neceſſary: to avoid confuſion from further ſub-diviſion, we will take another *fig.* (4) with ſimilar letters of reference as the preceding one. With N° 3, or extent *a* A of 90°, interſect at the point *b* from the points N and O, then with a fifth extent B *b* ſet off from B to Q, and the arc B Q will be the fifth part of the circumference. To biſect theſe five large arcs, take the ſixth extent A *b* and ſet it from B to P, which will be equal to the arc P Q, and, conſequently, will be a tenth part of the circumference. Again, without any further operation, the ſmall arc Q I, already marked, will be the 120th part of the circumference; and to obtain $\frac{1}{20}$th part of the ſame, in the quadrant B V *f*, the fifth extent B *b*, ſet off from *f* to V, will leave the arc B V equal to this quantity. And laſtly, to procure 240 equal arcs, take the extent *e* π, and ſet it over from ν to β, and from β to δ, ſo ſhall the arc P δ be the $\frac{1}{240}$th part of the circumference; but to ſubdivide all the circumference by the ſmall arc P δ of 1° 30′, the arc N G of 15° muſt firſt be divided into five parts of 3° each, without quinqueſection; thus, with the extent A *b* = B P, ſtep from B to the points P, Q, R, S, and it will fall next in E already marked; then with A *b*, as before, begin at L and put in the points *q* and *p* ſucceſſively; alſo from I put in π; and from O put in φ, by ſtepping the points ρ, ω, and τ; thus ſhall the points *p* P π and φ ſub-divide the arc N G into five equal arcs, and δ π will be found equal P δ, or $\frac{1}{240}$th part of the whole. After having obtained theſe five ſub-diviſions of 3° and 1° 30′, the firſt may be transferred, with the extent N G for inſtance, into other arcs of 15° in ſucceſſion, beginning with G C firſt, and uſing the points N, *p*, P, &c. as they occur, till the whole is gone through, after which the ſmall arcs thus transferred may be biſected by an extent δ N, going a ſecond time over the ſame points in ſucceſſion as before. Thus will the whole circumference be ſub-divided into 240 parts of each 1° 30′.

The eleventh or laſt problem on this ſubject, is to divide any arc B C (*fig.* 5.) into two equal parts in G. To do this; with radius A B, which has deſcribed the arc B C to be divided, and from the centres B and C, the two extremities of the arc, let the arcs A D and A E be deſcribed; let A D and A E be each made equal to B C; then from the points D and E, as centres, and with radius D C or E B, find by interſection the point F; laſtly, with the radius A F, and from the centres D and E, let the point G be interſected, which will fall in the circumference, if the operation is truly performed, and will alſo biſect the arc B C as was required.

By the help of the three remarkable points *a*, *e*, and *b*, in our *fig.* 4, the author of the Geometry of the Compaſs, has laid down in his twelfth and laſt book a dozen equations, ſome one of which may be applied to determine, by approximation, almoſt any ſmall arc of a circle that ſhall cut off a given quantity. It would be tedious to enter here minutely into his various calculations, but, for the ſake of amuſing the reader, we will ſelect the ſolutions of a few problems, without the annexed demonſtrations, which would enlarge our article too much.

Problem I.

To find the arc of one degree without the error of half a ſecond.

Solution.—Let the arc B *z*, below B, be 55° 30′, (in the circle which has been divided into 240 parts of each 1° 30′,) take the diſtance *b z*′, and from the point *e*, as a centre, deſcribe an arc to cut the circumference in ſome point Z, and the arc B Z′, above B, will be 52° 59′ [illegible], or 53° within about 25″; then in the diviſions between B and F is the diviſion 54°, or $\frac{18}{120}$ of the whole circle; there will therefore be 54° − 53° = 1° by approximation within the required degree of accuracy.

Solution 2.—Let the arc B Z be taken = 10° 30′, (by the diviſions exiſting) from the centre *a*, and with the diſtance *b* Z as radius, croſs the circumference in the ſaid point Z′ = 29° 29′ $\frac{2511}{2552}$, or 29° 30′ without an error of half a ſecond; then look for 28° 30′ in the exiſting diviſions, *viz.* $\frac{19}{240}$ of the circle, and the difference will be very nearly as before = 1°. This ſolution is leſs accurate than the former by about 4‴; the error being 29‴.

Problem II.

To find an arc of 15′ without an error of 1‴.

Solution.—Take the arc B *z* = 12° below B, the diſtance *e z* will be the chord of 87° 15′; with a radius of this extent, and from B, as a centre, cut the arc B F above, in the point Z′, and the arc B Z′ will be 87° 15′; but among the exiſting diviſions of the arc is 87°, or $\frac{29}{120}$th of the circumference; therefore, the difference of the two arcs is = 15′.

Problem III.

To find an arc of 10′ without an error of 10‴.

Solution.—Take the arc B *z* downward = 49° 30′, and the diſtance *b z* will be the chord of 38° 50′, without an error of 10‴; then, the diviſion 39°, or $\frac{13}{120}$, being found already, their difference on the circumference taken from B upwards, will be an arc of 10′.

Problem IV.

To find an arc of 6′ within 13‴.

Solution.—Take the chord of 45° from B to G above, and from the point *b* cut the circumference at *z*, which will be at 40° 6′, downwards from B, without an error of 13‴, but 40° counted downwards already exiſts, therefore the ſmall arc between is 6′.

Problem V.

To find an arc of 1′ within 22‴.

Solution.—Let B *z* downwards be = 27°; from the point *c* as a centre with radius *b z*, cut the circumference above at Z; and the arc B Z will be 29° 59′, with an exceſs of 22‴; therefore, the arc B N being 30°, the arc Z N will be 1′ within 22‴.

By ſuch means as theſe an arc of 9′ within 7‴ is determined; alſo, an arc of 20″ within 1‴; an arc of 15″ within 10‴; an arc of 12″ within 1‴; an arc of 10″ within 1‴; and an arc of 5″ within 2‴; but theſe laſt arcs are ſo minute in all ordinary circles, that we omit the ſolutions, as being of no utility.

We have hitherto ſuppoſed the circle divided into 360° with their ſub-diviſions, but the French have propoſed a centeſimal diviſion of the circle to be ſubſtituted, where each quadrant has 100° inſtead of 90°, making 400° in the whole circle, with each degree ſub-divided by hundreds, &c. This mode of dividing has been exemplified by L. Maſcheroni, in his Geometry of the Compaſs; and Mr. Troughton has deſcribed the method of graduating a circle in this way by his method, if it ſhould ever prevail in England; but, as there appears to be no advantage to the divider in affording biſections lower than 25°, and as our tables of logarithms, as well as aſtronomical tables, are adapted to the exiſting mode of dividing the circle, we are unwilling to lend our aid to the introduction of uſeleſs innovations, by entering more minutely into the ſubject.

L. Maſcheroni is the Italian geometrician, we are informed, who taught Bonaparte ſome problems, when in one of his campaigns in Italy, with one of which he puzzled the French mathematicians, and gained the reputation of being an adept in mathematics.

Graduation, in *Mineralogy*. When a mineral is diſcovered which is intermediate between other known ſpecies, and in different ſpecimens, or parts of the ſame ſpecimen, approaches very near to ſuch known minerals, it is ſaid to *graduate*, paſs into, paſs over to, or make tranſitions to, ſuch minerals. Frequently, the ſtrata of the earth graduate thus into each other, ſo that it is extremely difficult to define where one ſtratum ends and another of very different properties begins: theſe graduations are not uncommon between ſome lime-ſtone ſtrata and the chert beds in them. More frequently, each ſtratum is ſeparated by a thin layer or way-board of pulverulent matter, which occaſions the ſtrata to part freely; and often, in ſuch caſes, the parts of the ſtrata in contact with theſe way-boards differ nothing from the general maſs of each ſtratum, or there is no graduation between one ſtratum and the next in ſucceſſion.

Graduation *of ſaline Liquors*, in *Chemiſtry*, is a method of concentrating weak ſaline ſolutions, by pouring them through a heap of faggots, and expoſing them in this divided ſtate to a free current of air. See Muriate of *Soda*.

GRADUS Gemonic. See Gemoniæ.

GRÆA, Γραια, a name uſed by the old Greek writers for the wrinkled pellicle which ariſes upon milk in the boiling.

It was alſo uſed in a figurative ſenſe for the wrinkles in the ſkin of old people.

GRÆCIA, Greece, in *Ancient Geography*, a country of conſiderable extent, forming, as it were, the boundary or frontier between Europe and Aſia, and comprehending a great number of different ſtates and kingdoms. We have various opinions as to the etymology of the appellations Græci and Græcia. The moſt prevalent opinion traces the origin of theſe terms to Graicus or Græcus, the father, as ſome ſay, but, according to others, the ſon of Theſſalus, who gave its name to Theſſaly. Salmaſius ſuppoſes the name Græcus to be derived from Ragau or Rau, the ſon of Peleg, the fourth in deſcent from Shem, the ſon of Noah, by the tranſpoſition of a letter in order to ſoften the ſound. Pezron deduces it from Grain, ſignifying in Celtic *ancient*, and applicable to the Grecians by way of contradiſtinction to more modern people. But it has been objected to this etymology, that the Pelaſgi and Hellenes were a more ancient people than the Greeks. M. de Gebelin ſuppoſes the origin of the appellation to have been the word *rha*, or *rhe*, denoting vaſt or immenſe, in reference to the ſea which terminated the Adriatic gulf, on the borders of which the Greeks migrated ſouthwards, whence he forms *Raicus*, ſignifying this ſea, and by prefixing the guttural G to the lingual R, *Graicus*. The Greeks were alſo called Achæans, Hellenes, and Pelaſgi. The firſt of theſe appellations is ſuppoſed to have been derived from Achæus, the ſon of Xuthus, the ſon of Hellen, and father of Ion; the ſecond from Hellen, juſt mentioned, the ſon of Deucalion, and father of Dorus, from whom ſprung the Dorians; and the third, from a pretended founder Pelaſgus, who, taking poſſeſſion of the Peloponneſus, occaſioned its being denominated Pelaſgia. Grotius, Salmaſius, and Stillingfleet, names of conſiderable authority in diſquiſitions of this nature, ſuppoſe that the deſcendants of Peleg, the fourth in deſcent from them, the ſon of Noah, whom they ſuppoſe to have been the father of the Scythians, were the firſt who peopled Greece; and that they only ſoftened the name of Peleg, or Phaleg, their progenitor, and called them Pelaſgians. But Bochart (in his "Phaleg") ſhews, that both Phaleg and Ragau, and their deſcendants, remained in the confines of Media and Armenia; and that the Scythians were the deſcendants of Magog, and not of Phaleg or Ragau. Some have aſſerted that the moſt ancient name of all is that of Iones, which the Greeks themſelves derive from Xuthus, grandſon to Deucalion. Joſephus affirms (Ant. l. i. c. 7.) that their original is of much older date; and that Javan, the ſon of Japhet, and grandſon of Noah, and his deſcendants, were the firſt who peopled theſe countries; and in proof of this poſition the learned Bochart has alleged ſeveral ſtrong preſumptive arguments. He firſt adduces the authority of Joſephus, juſt cited; he then appeals to the name of the patriarch, יָוָן, which, without the points, ſounds more properly Ion than Javan; he next alleges the authority of Moſes, who ſays (Gen. x. 5.) that "by theſe" (the ſons of Japhet) "were the iſles of the Gentiles divided;" which, according to the genius of the Hebrew, mean, not iſlands properly ſo called, but all maritime countries, at any diſtance from Paleſtine, eſpecially thoſe which are along the Mediterranean; and he alſo refers to the prophets (Iſ. cap. ult. v. 19. Dan. viii. 21. x. 20) who call Græcia by the name יָוָן, Ion, or Javan, and hence the Jews have always called the Greek tongue יונית, Javanith. To theſe arguments he adds that the clear remains of Eliſha, Javan's eldeſt ſon, are ſtill to be found in that of Elis, one of the ancient kingdoms of the Peloponneſus.

GRÆCIA, or *Ancient Greece, Geography of.* Excluſively of the provinces of Epirus and Macedonia, which long remained barbarous and uncultivated, the continental poſſeſſions of the Greeks (ſays Dr. Gillies,) were nearly equal to Scotland in extent. In its length, comprehended between the 36th and 41ſt degrees of N. latitude, the whole country is almoſt equally divided by two oppoſite gulfs, compreſſing between them a mountainous neck of land, to the breadth of only five miles, into the peninſula of Peloponneſus, and the territory extending northwards, from the extremity of the Corinthian iſthmus to the ſouthern frontier of Macedonia. The Peloponneſus, 160 miles in length, and ſcarcely 100 in breadth, is every where interſected by mountains, particularly the towering ridges of Zarex and Taygetus. During the flouriſhing ages of Greece, this ſmall peninſula contained ſeven independent communities of unequal power and fame, which ranked in the following order: the comparatively large, and highly diverſified, territory of Laconia; the fruitful vale of Argos; the extenſive coaſt of Achaia; the narrow but commercial iſthmus of Corinth; the central and mountainous region of Arcadia; together with the more level countries of Elis and Meſſenia, which are throughout better adapted to tillage, than any other provinces of the Peloponneſus. The Grecian poſſeſſions beyond the iſthmus of Corinth were more conſiderable, extending above 200 miles from eaſt to weſt, and 150 from north to ſouth. They were naturally divided by the long and intricate ridges of Olympus, Pindus, Oeta, and Oſſa, into nine ſeparate provinces; which, during the celebrated ages of Grecian freedom, were occupied by nine independent republics. They comprehended the extenſive and fertile plains of Theſſaly and Bœotia, both of which were, in early times, much expoſed to inundations, and the latter, abounding in ſubterranean caverns, was peculiarly ſubject to earthquakes; the leſs fertile, but more ſecure territory of Attica; the weſtern provinces of Ætolia and Acarnania, encompaſſed on one ſide by dangerous ſeas, and confined on the other by almoſt impaſſable mountains; and the four ſmall rocky diſtricts of Phocis, Doris, Locris, and Megara.

Theſe names and diviſions (ſays the above cited hiſtorian) which remained to the lateſt times, are pretty accurately marked by Homer, whoſe poems continued, through ſucceeding ages, to be the approved ſtandard and legal code, to which neighbouring communities appealed, in adjuſting their diſputed boundaries. This qualification, however, muſt be admitted with two exceptions. During the Trojan war, the extenſive province of Theſſaly ſent forth above a fourth part of the whole Grecian ſtrength, and was divided among many warlike leaders. But when commerce, navigation, and the mechanic arts, enriched and adorned the middle and ſouthern diviſions of Greece, the northern diſtrict of Theſſaly loſt its ancient pre-eminence. The other exception aroſe from the extenſive power of the houſe of Pelops, which had, by fortunate marriages and rich ſucceſſions, acquired dominion over the northern and eaſtern parts of the Peloponneſus, formerly containing ſeveral independent principalities, and, after the misfortunes of Agamemnon and his family, again divided into the immortal republics of Sparta, Argos, Corinth, and Achaia. The following table will exhibit at one view the principal ſtates of Greece, with ſome of their towns and rivers, referring to each article for a further account, and obſerving that we have admitted into it Macedonia, though it was not properly a province of Greece till after the reign of Philip, or rather that of Alexander, and alſo Epirus and Illyria.

GRÆCIA.

TABLE

Of the Principal Geographical Diviſions of Greece.

Natural Diviſions of Græcia, *or* Greece.	Terra Firma.	Peloponnesus.	Argolis.	Rivers.—*Inachus*, *Eraſinus*. Towns.—Argos, *Mycenæ*, *Epidaurus*, &c.
			Laconia.	R. *Eurotas*. T. Sparta, *Amyclæ*, *Gythium*, *Teucrium*.
			Messenia.	R. *Pamiſus*. T. Messene, *Stenyclarus*, *Colonides*.
			Elis.	R. *Alpheus*, *Anigrus*, *Selleis*. Div. *Triphylia*, *Piſatis*, *Cæle-Elis*. T. *Olympia*, *Piſa*, Elis.
			Achaia.	R. *Melas*, *Crathis*. T. *Dyme*, Patræ, *Ægium*.
			Sicyonia.	R. *Aſopus*. T. Sicyon, *Phlius*.
			Corinthia.	T. Corinthus, *Lechæum*, *Cenchræ*.
			Arcadia.	R. *Alpheus*, *Erymanthus*, *Aoranius*. T. Megalopolis, *Mantinea*, *Tegea*, *Orchomenus*, *Phigalia*.
		Græcia Propria.	Attica.	T. Athenæ, *Eleuſis*, *Marathon*, *Sunium*, prom.
			Megaris.	T. Megara, *Nyſæa*.
			Bœotia.	R. *Cephiſſus*, *Copais*, lac. *Aſopus*. T. Thebæ, *Orchomenus*, *Cheronæa*, *Tanagra*, *Eleuteræ*, *Theſpiæ*.
			Phocis.	R. *Cephiſſus*. T. Delphi, *Elatia*, *Cryſſa*, *Anticyra*.
			Doris.	T. *Cytinium*.
			Locris.	Locri *Ozolæ*, Amphissa, *Naupactus*. Locri *Epicnemidii* . . . Cnemides. Locri *Opuntii* . . . Opus.
			Ætolia.	R. *Acheloüs*, *Evenus*. T. *Thermus*, *Calydon*, *Chalcis*.
			Acarnania.	Argos *Amphilochicum*, *Stratus*, *Actium*.
		Thessalia.		R. *Peneus*, *Oncheſtus*, *Sperchius*. T. Larissa, *Pharſalus*, *Pheræ*, *Demetrias*.
		Epirus.		R. *Acheron*, *Avas*. T. *Buthrotum*, *Nicopolis*.
		Illyria.		T. *Epidamnus*, *Apollonia*.
		Macedonia.		R. *Erigon*, *Axius*, *Strymon*, *Haliacmon*. T. Edessa, *Pella*, *Theſſalonica*, *Olynthus*.
	Islands.	To the Weſt.		*Corcyra*, *Leucadia*, Cephallenia, *Dulichium*, *Zacynthus*.
		To the South.		*Cythara* . . . Creta.
		To the Eaſt.		*Thera*, *Naxia*, *Paros*, *Delos*, *Myconus*, *Tenos*, *Andros*, Ceos, Eubœa, *Scyros*, *Thaſos*.

The ancient authors who are to be conſulted with regard to the different periods of the geography of Greece, are Homer, for the more remote times, in his account of the forces collected for the ſiege and capture of Troy; Strabo, who avails himſelf of ample materials to which he had acceſs; Pauſanias, who details the reſults of his own travels and obſervations; and Ptolemy, who furniſhes an uſeful nomenclature of the ſtates and chief towns, with their longitudes and latitudes.

GRÆCIA, or *Ancient Greece, hiſtory of.* The traditions of the Greeks (ſays the learned hiſtorian, Dr. Gillies,) agree with the authentic records of ſacred hiſtory in repreſenting the countries afterwards known by the names of Thrace, Macedon, and Greece, as peopled at an earlier period than any other portion of the weſtern world. The ſouthern corner of Europe, comprehended between the 36th and 41ſt degrees of latitude, bordering upon Epirus and Macedonia towards the north, and on other ſides ſurrounded by the ſea, was inhabited, above 18 centuries before the Chriſtian era, by many ſmall tribes of hunters and ſhepherds, among whom the Pelaſgi and the Hellenes were the moſt numerous and powerful. The barbarous Pelaſgi venerated Inachus, as their founder; and, for a ſimilar reaſon, the more humane Hellenes reſpected Deucalion. From his ſon Hellen, they derived their general appellation, which originally denoted a ſmall tribe in Theſſaly, and from Dorus, Eolus, and Ion, his more remote deſcendants, they were diſcriminated by the names of Dorians, Eolians, and Ionians. The Dorians took poſſeſſion of that mountainous diſtrict of Greece, afterwards called Doris; the Ionians, whoſe name was gradually loſt in the more illuſtrious appellation of Athenians, ſettled in the leſs barren parts of Attica; and the Eolians peopled Elis and Arcadia, the weſtern and inland regions of the Peloponneſus. Notwithſtanding many partial emigrations, theſe three original diviſions of the Hellenes generally entertained an affection for the eſtabliſhments which had been preferred by the wiſdom or caprice of their reſpective anceſtors; a circumſtance which remarkably diſtinguiſhed the Hellenic from the Pelaſgic race. While the former diſcovered a degree of attachment to their native land, ſeldom found in barbarians, who live by hunting or paſturage, the latter, diſdaining fixed habitations, wandered in large bodies over Greece, or tranſported themſelves into the neighbouring iſlands; and the moſt conſiderable portion of them gradually removing to the coaſts of Italy and Thrace, thoſe that remained melted away into the Doric and Ionic tribes. At the diſtance of 12 centuries, obſcure traces of the Pelaſgi occurred in ſeveral Grecian cities; a diſtrict of Theſſaly always retained their name; and their colonies continued, in the fifth century B. C., to inhabit the ſouthern coaſt of Italy, and the ſhores of the Helleſpont; and in thoſe widely ſeparated countries, their ancient affinity was recognized in the uniformity of their rude dialect and barbarous manners, extremely diſſimilar to the cuſtoms and language of their Grecian neighbours. Such is the account of the firſt ſettlers in Greece, given by Dr. Gillies on the cited authorities of Herodotus, Dionyſius Halicarn., Pauſanias, Thucydides, Diodorus Siculus, and Strabo. Modern authors, however, have entertained different opinions on this ſubject. Some have ſuppoſed that the Pelaſgi ſucceeded the Hellenes, and others have conſidered them as the ſame people under different denominations. According to M. de Gebelin, Moſes, the Jewiſh legiſlator, has given us the primitive origin of the Greeks. In tracing the genealogy of the deſcendants of Noah he ſays that Japhet, one of the ſons of Noah, had ſeven ſons: that the fourth was called Ion, and that he was the father of Eliſa, Tharſis or Thraſis, Ketim, and Dodanim; this Ion was the father of the Greeks, and M. de Gebelin labours to find among the Greeks four nations formed by his four ſons. With this view, he ſays, that Pelaſgia comprehended the whole territory between the Danube and the ſea of Peloponneſus; and here we may diſcover, as he conceives, the reſpective ſituation of each of Ion's four ſons. Thrace acknowledges Tharſis or Thraſis for its founder; Ketim poſſeſſed the country of the Getæ, N. of Macedonia, and Macedonia itſelf; Dodanim had the country that lay between Macedonia and the Peloponneſus, inhabited by the Dorians; and Eliſa deſignated the inhabitants of the Peloponneſus. This author, in no ſmall degree indulging his imagination, and yet exerciſing a very conſiderable degree of ingenuity and attention to facts, obſerves, that the hiſtory of Deucalion is the foundation of the Greek chronology and hiſtory: this Deucalion is diſtinguiſhed by his deluge, his ark, and his being the father of the Greeks or Hellenes. All theſe circumſtances afford a preſumption that Deucalion and Noah were the ſame perſon. He alſo ſays, that the fable of the Argonauts and their voyage to Colchis is a copy of the navigation of Noah. Phryxus, or the "man ſaved," in the Grecian mythology, is Noah. He diſcovers alſo other coincidences, which lead him to conclude, not only that Noah and Deucalion, but that Ion and Hellen, the reputed father of the Greeks, were the ſame perſons; and that the Hellenes and Pelaſgi were the ſame people. According to this writer, the Pelaſgi were the ſole poſſeſſors of the whole country which extended itſelf from the banks of the Danube, to the ſea of the Peloponneſus; they peopled Thrace, Getia, Macedonia, Illyria, Epirus, Theſſaly, the Phocide, Attica, and the Peloponneſus; they ſent colonies to the iſle of Crete, to Etruria, and to the ſouth of Italy; and others croſſed the Danube, and were denominated Dacians and Getæ. Greece was in this ſtate, ſays M. de Gebelin, when ſome colonies of ſtrangers arrived on its coaſts, as Cecrops at Athens, Danaus at Argos, and Cadmus in Bœotia. Theſe, he ſays, came not from Egypt, but from Phœnicia, a neighbouring country. The firſt inhabitants of Greece, whenceſoever they came, were, in a very conſiderable degree, like the anceſtors of other people, barbarous and ſavage; and the Hellenes, whoſe manners were mild and gentle, contributed in ſome meaſure to civilize them; but their efforts produced effect very ſlowly. At length, however, the happy poſition of their country, forming a kind of frontier between Europe and Aſia, and divided only by a narrow ſea from Egypt and Syria, and not far remote from thoſe eaſtern regions which were anciently moſt populous and flouriſhing, invited ſtrangers firſt to viſit, and afterwards to dwell among them. The Greeks were not inſenſible of their obligations to ſtrangers for the moſt important diſcoveries, not only in religion, but in agriculture and the arts; but as they advanced to ſuperiority in arts and arms, above ſurrounding nations, they vainly fancied that their infancy was reared by the gods: and to the gods they transferred the merit of many uſeful inventions, that had been communicated to them or their progenitors by their ancient viſitants: and it muſt be acknowledged, that the worſhip of ſeveral divinities was introduced at the ſame time, and by the ſame perſons, who made known to them the arts moſt ſubſervient to the purpoſes of human life.

From the middle of the 16th to the middle of the 14th century, B. C. an inundation of Egyptians, Phœnicians, and Phrygians overflowed the Hellenic coaſts. The principal colonies were conducted by Cecrops and Danaus, Egyptians, who reſpectively ſettled in Athens and Argos; Cadmus, a Phœnician, who founded Thebes in Bœotia; and Pelops,

lops, a Phrygian, whoſe deſcendants, by intermarriages with thoſe of Danaus, king of Argos, and Tyndareus, king of Lacedæmon, or Sparta, acquired in the perſon of Agamemnon ſo powerful an aſcendant in the Peloponneſus. The family of Deucalion ſtill reigned in Theſſaly; but Thebes, Athens, Argos, and Sparta, which were long regarded as the principal cities of Greece, thus fell under the dominion of four foreign lines of princes, whoſe exploits, and glory, and misfortunes are immortalized by the firſt and nobleſt productions of Grecian genius; ſuch are the works of Homer and Pindar, and of the Greek tragedians.

The invaders of Greece introduced many important and uſeful improvements. They brought into that country the knowledge of the Phœnician alphabet; they aſſiſted them in the operations of agriculture; they multiplied the rites of religion; diſcovered to them ſeveral uſes of the metals; and, in return, adopted the Grecian language, and generally conformed to the Grecian cuſtoms and inſtitutions. By the Phœnicians they were taught and encouraged to brave the dangers of the ſea, and to maintain a commercial intercourſe with each other, as well as with foreign nations. Their country, indeed, was peculiarly advantageous for this purpoſe; three ſides of it being waſhed by the ſea, and being ſurrounded by numerous iſlands, and abounding in excellent harbours. Greece, however, was ſlow in availing itſelf of the advantages it enjoyed; and in making improvements in commerce, as well as in agriculture, and other uſeful arts. Many circumſtances concurred to retard its improvement. The inhabitants of different parts of the country were unconnected on account of the creeks and rivers, as well as the mountains and promontories, that rendered Greece different from any other part of Europe. The Grecian ſtates were ſmall; each city was at war with its neighbour, and want of union and mutual concurrence prevented their advancement in ſcience and the arts. Beſides, their coaſts were ravaged by pirates, and the metals, inſtead of being formed into uſeful implements of agriculture, were converted into inſtruments of deſtruction, partly for hoſtility and partly for ſelf-defence: and the inland country was invaded by Thracians, Amazons, and other northern ſavages. But theſe irruptions and ravages of the barbarians occaſioned the inſtitution of the Amphictyonic council, which reſtored ſome degree of preſent tranquillity to Greece, and laid the foundation of its future grandeur. This council produced, after a conſiderable interval of time, *viz.* in the year 1263 B. C. the Argonautic expedition, an undertaking which was attended with a beneficial effect on the manners and character of the Greeks. (See ARGONAUTIC.) In the progreſs of the Greeks towards civilization, they perceived the advantages of political confederacy, before they became ſenſible of the benefits of civil union; and accordingly a federal aſſociation between different communities was formed before the members of any one ſtate had been ſufficiently united in the ſyſtem of domeſtic policy. In order to cement ſuch diſorderly communities by laws and governments, they had recourſe to the wiſe inſtitutions and examples of the Cretans, which are repreſented not only as the moſt ancient, but as the beſt regulations that ever were eſtabliſhed in any portion of the Grecian territory. (See CRETE.) Theſeus communicated the Cretan improvements to the Athenians; from Athens they were diffuſed through Attica, and in proceſs of time through the neighbouring provinces of Greece; inſomuch, that at the commencement of the Trojan war, in 1193 B. C. all the Grecian ſtates had adopted one uniform ſyſtem of government, uniting the independent ſpirit of European freedom with the reſpectful veneration of Egyptian and Aſiatic ſuperſtition.

Of the mythology and manners of the Greeks in the heroic ages, as well as their geography and hiſtory, Homer, whilſt he has indulged his fancy, has given us an accurate delineation; and ſuch as was conformable to the ſyſtem of opinions and belief which prevailed among his countrymen. The religion, or mythology of the Greeks, was adapted to the melioration of their condition, and to the improvement of civil ſociety. Unlike that of the rude inhabitants of ancient Germany, among whom the offices of prieſt and king were adminiſtered by different perſons, the ſceptre, which denoted the connection of civil power with ſacred protection, was conferred, among the Greeks, on thoſe who, while they continued the humble miniſters of the gods, were appointed to be the chief, but accountable guardians of the people. The ſame voice (ſays Dr. Gillies), that ſummoned the warriors to arms, or that decided, in time of peace, their domeſtic connections, conducted the order of their religious worſhip, and preſided in the prayers and hymns addreſſed to the divinity. Theſe prayers and hymns, together with the important rite of ſacrifice (which was likewiſe performed by royal hands), formed the *ceremonial* part of the Grecian religion. The *moral* was far more extenſive, including the principal offices of life, and the nobleſt virtues of the mind. The uſeful quality of courage was peculiarly acceptable to the ſtern god of war; but the virtues of charity and hoſpitality were ſtill more pleaſing to the more amiable divinities. To this purpoſe Homer ſays (Od. xiv. 56.) "all ſtrangers and beggars come from Jove." The ſubmiſſion of ſubjects to their prince, the duty of a prince to preſerve inviolate the rights of his ſubjects (Il. xvi. 385.), the obedience of children to their parents, the reſpect of the young for the aged, the ſacred laws of truth, juſtice, honour, and decency, were inculcated and maintained by the awful authority of religion. Even the moſt ordinary tranſactions of private life were conſecrated by the piety of the Greeks. They ventured not to undertake a voyage, or a journey, without ſoliciting the propitious aid of their heavenly protectors. Every meal (and they had three in a day, *viz.* αριϛον, δειπνον, δορπον), was accompanied with a ſacrifice and libation. The common forms of politeneſs, the cuſtomary duties of civility, were not decided by the varying taſtes of individuals, but defined by the preciſe voice of the gods. The laws of religion were guarded and enforced by correſponding ſanctions. The dreaded vengeance of imaginary powers was eſtabliſhed in the Grecian creed; and it appears from the writings of Homer throughout, that every important event, proſperous or adverſe, which happened either to individuals or to nations, appeared to the Greeks, as the reward of their religion and virtue, or the puniſhment of their irreligion and vice. The principles above ſtated are confirmed not only by the writings of Homer and Heſiod, but by almoſt every page of Herodotus, of Pindar, as well as of the Greek tragedians and hiſtorians.

The origin of the gods of Greece has afforded a ſubject of elaborate diſcuſſion; and many learned writers have traced it to Paleſtine, Egypt, and other nations, whence the firſt ſettlers or future emigrants ſprung. By the dim light of etymology and tradition (ſays the ingenious hiſtorian of Greece), and the deceitful glare of legend and fable, inquiſitive men have endeavoured to trace the corrupted ſtreams of Pagan worſhip to the pure fountain of the Jewiſh diſpenſation; and it muſt be acknowledged, that the general doctrine of providence, the rebellion in heaven, the ſtate of innocence, the fall of man, atonement by ſacrifice, and a future ſtate of retribution, for which the preſent life is only preparatory, are tenets, all, or ſome of which, are found in the traditions of all nations, Greeks and Barbarians. (See Heſiod, Oper. and Di. v. 110, 165. Theog. v. 220. 725.) But our author obſerves, that the majeſty of Jehovah is very feebly repreſented by the united power of Homer's divinities; and that the mythology of the Greeks is of ſuch a peculiar texture, that, whenceſoever originally derived, it muſt have undergone a particular modification in the Grecian ſoil; nor (he ſays) is it eaſy to concur with the opinion of writers who bring it immediately from Egypt, Chaldæa, or Leſſer Aſia, when we conſider that there is not the ſmalleſt veſtige in Homer of the judicial aſtrology which prevailed ſo much in the two firſt countries, (Diod. Sic. l. ii. Exod. ch. vi. Plin. l. xxv.), or of the worſhipping of idols, which almoſt univerſally prevailed in the laſt. (Old Teſtament, paſſim.) Dr. Gillies traces the origin of the Grecian faith and worſhip in the natural paſſions of the human heart, the hopes, the fears, the wants, the miſery of man, which have in all ages rendered him a prey to the terrors of ſuperſtition.

The great pillar of ſuperſtition, raiſed by the anxious paſſions of men, was fortified in Greece by a peculiar ſenſibility of character, which exerts itſelf in the ardour of ſocial affection, and ſtrengthens, by a thouſand aſſociations, their belief of inviſible and intelligent powers. The nature, the characters, and the occupations of the gods, were ſuggeſted by the lively feelings of an ardent, rather than by the regular invention of a cultivated mind. Theſe celeſtial beings were ſubject to the blind paſſions which govern unhappy mortals: their wants, and their deſires, were ſimilar to thoſe of man. But what was wanting in the dignity and perfection, was ſupplied by the number of the gods. Homer only deſcribes the principal and reigning divinities; but Heſiod, who gives the genealogical hiſtory of this fanciful hierarchy, makes the whole number amount to 30,000. Every virtue had its protector, every quality of extenſive power in human life had its patron, and every grove, mountain, and river its favourite inhabitants. (See GODS.) The religious creed of the Greeks, compoſed of materials, in great meaſure created by fancy, formed by poetry into beauty, and improved into uſe by policy, became the happieſt antidote againſt the furious reſentment, the ſavage cruelty, and the fierce ſpirit of wild independence, which uſually characterizes the manners of barbarians. Upon the whole, the ancient and venerable ſuperſtition of the Greeks was diſtinguiſhed above moſt other falſe religions, by the uncommon merit of doing much good, without ſeemingly occaſioning any conſiderable harm to ſociety. The Grecian tenets, while they inculcated profound reſpect to the gods, had no tendency to break the ſpirit or to repreſs the courage of their warlike votaries. In order to avert the calamities threatened by the anger of their divinities, they did not recur to the infliction of tortures on themſelves, but they repaired the wrongs which they had committed againſt their fellow-citizens, or compenſated, by new attentions, for the neglect ſhewn to the ceremonies of their national worſhip. In their eſtimation, the doing of injury to men, and the omiſſion of prayer to the gods, were the principal cauſes of the divine diſpleaſure, which they were anxious to avert by a diligent practice of moral duties. The dangerous power of oracles, the abuſed privileges of aſylums, the wild raptures of prophetic enthuſiaſm, the abominable ceremonies of the Bacchanalia, and the horrid practice of human ſacrifices, all which are circumſtances that cover with deſerved infamy the latter periods of Paganiſm, were unknown to the good ſenſe and purity of the heroic ages; nor is there to be diſcovered the ſmalleſt veſtige of any of theſe wild or wicked inventions, either in the writings of Homer, or of his cotemporary Heſiod. Their religious ſyſtem communicated its beneficial influence to the civil and military inſtitutions of the Greeks, to the laws of nations, as well as to the regulations of internal policy, and to the various duties of domeſtic as well as of ſocial life.

In examining the political ſtates of the Greeks, during the heroic age, we ſhall find that they deſerve the title of republics, rather than that of monarchies. The ſoldiers of any warlike tribe fought and conquered, in their attack of a more fertile territory than their own woods and mountains, not for their leaders, but for themſelves: and the land acquired by their united valour was conſidered as a common property. No diſtinction was known among them, but that which was occaſioned by the difference of perſonal merit and abilities. This difference raiſed a chief or leader to the head of each ſociety; and his ſuperior uſefulneſs in this ſtation, was rewarded by the gratitude of his tribe with a valuable portion of ground, ſeparated from the common property. (Il. xii. 310.) This perſon, who commanded in the field, became the arbiter and judge of their civil differences, and he was inveſted with the honourable office of preſiding in their religious ſolemnities. Theſe important functions of prieſt, judge, and general, conferred on the beſt and braveſt in each particular tribe, were conferred, upon the union of ſeveral tribes into one ſtate or nation, on the beſt and braveſt of all the different leaders. The various ſtates of Greece formed a general confederacy, in which the council of princes regulated the reſolutions of the monarch, and the voice of the aſſembly ruled that of the council; and ſo likewiſe in each particular kingdom, the deciſions of the ſenate prevailed over the will of the prince, and the acknowledged majeſty of the people controuled the deciſions of the ſenate. The ſame diſtribution of power took place in every particular village.

The civil rights of the Greeks were maintained by the ſame ſimplicity which regulated the political ſyſtem. As the price of ſubmitting to the reſtraints of ſociety, a man was ſecured in the enjoyment of his life and property: his moveables were equally divided, at his death, among his deſcendants; and the unnatural right of primogeniture, which, in order to enrich the eldeſt ſon, reduces the reſt of the family to want and miſery, was altogether unknown to the equal ſpirit of the Grecian inſtitutions. Cauſes reſpecting property were decided by the firſt magiſtrate, or by judges of delegated authority. The proſecution of murderers belonged to the relations of the deceaſed, who might accept a compenſation in money for the loſs which the family had ſuſtained; but in defect of this compoſition, all the members of the tribe concurred with the aggrieved, in either puniſhing the murderer by death, or compelling him to leave the ſociety.

The hiſtory of the heroic ages of Greece preſents the moſt intereſting picture of conjugal love, parental affection, and filial duty. The inſtitution of marriage was aſcribed to the gods; and it was celebrated with all the pomp of religious feſtivity. Adultery was held in the greateſt deteſtation, and always mentioned with the ſame horror as murder. The guilty perſon might purchaſe immunity, but more frequently eſcaped death by voluntary baniſhment. It has been erroneouſly ſaid, that, in ancient Greece, wives, as well as concubines, were the ſlaves of their huſbands, and that they were purchaſed by them. The attention of women was chiefly confined to domeſtic care and occupations, which did not require any great degree of ſtrength, courage, or wiſdom. Weaving and embroidery, which were employments of females, were practiſed by ladies of the higheſt rank, and even by queens; and they were alſo entruſted with the education of their children. They were permitted to join in the celebration of religious rites and ceremonies, and many of them were conſecrated to the ſervice of particular divinities.

War, being the principal employment of the Greeks in the heroic ages, they ſupplied by courage what they wanted in ſkill. They marched to the field in a deep phalanx, ruſhed impetuouſly to the attack, and bravely cloſed with their enemies. Their principal weapon was the ſpear; and when the uſe of this failed, they drew their ſwords, and ruſhed impetuouſly on the foe. The Greeks had alſo bows, ſlings, and darts; which were chiefly uſed in their military paſtimes. Their defenſive armour was complete: a light helmet, adorned with plumes, covered the head and face, a fine corſlet defended the breaſt, greaves of braſs deſcended to the feet, and an ample ſhield, looſely attached to the ſhoulders, turned in all directions, and oppoſed its firm reſiſtance to every hoſtile aſſault. Their cloſe compact combats ſerved to excite the moſt furious paſſions, and to embitter national animoſity by perſonal hatred and revenge. Before any war could be undertaken, it was neceſſary to diſpatch ambaſſadors, who explained the injury that had been done, demanded ſatisfaction, and if this were refuſed, denounced the reſolution of their community to proſecute its claim by force of arms. After the commencement of war, the characters of heralds were equally reſpected by friends and foes; and they travelled in ſafety through the midſt of embattled hoſts. The uſe of poiſoned weapons was forbidden, under pain of the divine diſpleaſure. The will of the gods required that life ſhould be ſpared, when a ſufficient ranſom was promiſed; and when a treaty of peace was concluded, without any ratification but the honour of the contracting parties, the perfidious wretches who betrayed the ſanctity of their engagements were devoted, amidſt libations and ſacrifices, to the fury of the terrible goddeſſes. (Iliad, iii.)

From the practice of war we may now turn our attention to the arts of peace. Paſturage and agriculture ſupplied the Greeks with food and clothing; but their implements for preparing theſe articles were very imperfect. The principal produce of their fields was barley, which ſupplied the ordinary food of men as well as horſes. Mills were unknown, and the grain was bruiſed between two large ſtones with the hand. They cultivated the olive, but knew not how to extract the oil; and though their ſoil was favourable to the grape, the juice was obtained by a tedious and operoſe proceſs, which rendered wine ſcarce and dear. Of the mechanic arts, weaving was beſt underſtood; and the hatchet, wimble, plane, and level, are the tools mentioned by Homer, who ſeems to have been unacquainted with the ſaw, the ſquare, and the compaſs. Homer does not mention the orders of architecture; and pillars are the only ornaments aſſigned to the edifices which he deſcribes. The roofs of the houſes, conſiſting of two floors, and ſurrounded by a wall, were flat. The invention of enamelled metals had been cultivated with peculiar ſucceſs; and though painting, properly ſo called, was rude and unformed during the age of Homer, the genius of the divine poet has deſcribed the rudiments of his kindred art with ſuch graces as would adorn its moſt refined ſtate of perfection. Muſic was much practiſed among the early Greeks. (See *Muſic of the* GREEKS.) The ſciences were in a low and imperfect ſtate. For arithmetic they had little occaſion; by means of their aſtronomy they were enabled to obſerve the conſtellations which directed the adventurous courſe of the mariner; but their navigation was ſo imperfect, that they ſeldom abandoned the coaſts. The only ſtars mentioned by Homer are the Great and Little Bear, the Pleiades, the Hyades, Orion, and the Dog-ſtar. Of their games, we give an account under GAMES and GYMNASTICS. As to their general character, we ſhall tranſcribe two or three paragraphs from the firſt volume of Dr. Gillies's Hiſtory of Ancient Greece, to which we have been indebted in the compilation of this article. "The Greeks," ſays Dr. G., "had advanced beyond that uniform inſipidity of deportment, that ſullen ferocity of manners, and that hardened inſenſibility of heart, which univerſally characterizes the ſavage ſtate. They ſtill poſſeſſed, however, that patient intrepidity, that noble ſpirit of independence, that ardent attachment to their friends, and that generous contempt of pain, danger, and death, which render the deſcription of the wild tribes of America ſo intereſting to a philoſophic mind. Of two principal enjoyments of life, ſtudy and converſation, they were little acquainted, indeed, with the conſolations and pleaſures of the firſt, the want of which was compenſated by the ſincerity, the confidence, the charms of the ſecond. Their ſocial affections were leſs comprehenſive in their objects, but more powerful in their effects than thoſe of poliſhed nations. A generous chief ruſhes to certain death to revenge the cauſe of his friend; yet refuſes to the prayers of an aged parent the melancholy conſolation of interring the remains of his favourite ſon, till the correſponding image of his own father ſtrikes his mind, and at once melts him to pity. (Iliad, xxiv.) The imaginary wants and artificial paſſions which are ſo neceſſary to urge the hand of induſtry, and to vary the purſuits of men, in improved commercial ſocieties, were ſupplied to the Greeks by that exceſſive ſenſibility, which intereſted them ſo deeply in the affairs of their community, their tribe, their family, and their friends, and which connected them by the feelings of gratitude even with the inanimate objects of nature. As they were not acquainted with the ſame diverſity of employments, ſo neither were they fatigued with the ſame giddy round of diſſipated pleaſures which augment the ſplendid miſery of later times. Though ignorant of innumerable acts which adorn the preſent age, they had diſcovered one of ineſtimable value, to render the great duties of life its moſt entertaining amuſement. It will not, perhaps, be eaſy to point out a nation who united a more complete ſubordination to eſtabliſhed authority with a higher ſenſe of perſonal independence, and a more reſpectful regard to the dictates of religion with a more ardent ſpirit of martial enterprize. The generous quality of their political eſtabliſhments, and their fancied intercourſe with the gods, conſpired to raiſe them to a certain elevation of character which will be for ever remembered and admired. This character was rendered permanent in Sparta, by the famous laws commonly aſcribed to the invention of Lycurgus, but which will appear (under that article) to have been "almoſt exact copies of the cuſtoms and inſtitutions that univerſally prevailed in Greece during the heroic ages." The character of the Greeks in ſubſequent periods will appear in the account of the ſeveral ſtates, provinces, or kingdoms, which they occupied.

The general hiſtory of Greece may be divided into four periods, marked by as many memorable epochas. The *firſt* extends to the ſiege of Troy in the year 1184 B.C.; the era of its commencement is not preciſely aſcertained; but if we date it with the foundation of the kingdom of Sicyon by Ægialeus in the year 2089 B.C., it laſted 905 years. This was properly the infancy of Greece; and comprehends the eſtabliſhment of the kingdoms of Sicyon, of Argos, 1856 B.C., of Athens, 1556 B.C., of Troy, 1546 B.C., of Thebes, 1493 B.C., of Mycenæ, 1344 B.C.; the deluge of Ogyges, 1764 B.C. and that of Deucalion, 1503 B.C.;

the murder committed by the daughters of Danaus on their huſbands, 1485 B.C.; the introduction of the Phœnician letters into Greece, 1493 B.C.; the legiſlation of Minos in Crete, 1406 B.C.; the Argonautic expedition, 1263 B.C.; the exploits of Theſeus, 1234 B.C.; the war of the ſeven heroes againſt Thebes, 1225 B.C., &c. &c.
